Mr. John Forster, of Gray's Inn, represented the plaintiff, Oswald Postlethwaite, a poet, of Gossamer-road, Chelsea. On June 5th, 1926, the cook, Flora Macdonald, had entered the poet's room with his tea, interrupting a moment of inspiration. She had also opened the window, so that his papers were blown about the room. Seizing what he believed to be a ruler, the enraged poet had hurled it at the cook, finding later on that he had really thrown a knife at her. Although he had long been subject to outbursts of fury if interrupted at work, this apparently homicidal attack alarmed his sister, who sent for the local practitioner, Dr. Phipps. The doctor's questions enraged the poet, who became violent. Dr. Dementius Precox, an eminent alienist, was therefore called in, and made another examination, which still further accentuated the anger of the patient, who attacked the specialist. Dr. Phipps and the odd-job man were called to the rescue, and hyoscine was administered. The stuporous poet was then removed, under an Urgency Order, signed by Dr. Precox, to the West Central Asylum. On this Order the doctor had stated, as facts indicating insanity, that the poet believed that there was a conspiracy between the Prime Minister, the Archbishop of Canterbury, and all the Members of Parliament to prevent the publication of his poems, that he stated that no one could understand his poetry, and that he was a reincarnation of the poet Ovid. Mr. Forster submitted that it was for Dr. Precox to prove that the poet was not in fact a reincarnation of the poet Ovid. The qualifications of Dr. Precox were given as M.D. Camb. and F.R.C.P. Lond., and were only peculiar in that he had also an honorary D.Sc. Aberdeen. Another item he had entered on the certificate was that the patient had called Dr. Precox's "aid to monocular vision" the "green eye of the little yellow god," and dealt him a blow on the face which dislodged that apparatus. As soon as the influence of the drug had passed off the poet behaved with such restraint that the superintendent of the asylum, Dr. Sigmund Waterman, discharged him at the end of a week. Mr. Postlethwaite then conceived the idea that Dr. Phipps and his sister were plotting to get him out of the way in order that they might marry, and consulted his friend and pastor, the Rev. Josiah Pentwhistle, a Fire Baptist, who advised him to bring the present action for wrongful detention and defamation of character.

Mr. Forster, having outlined the plaintiff's case as above, then called witnesses.

Evidence for the Plaintiff.

Mr. Oswald Postlethwaite, a lugubrious gentleman in dark glasses, with a lock of damp black hair over his forehead, deposed to the truth of the facts as outlined. He admitted that he was a genius, and only a moderately-tempered genius. The cook had on this occasion caused him to lose a moment of priceless inspiration which might never return. He had published one volume only, and that under the auspices of the Fire Baptists. Other publishers had refused to consider his work. He still believed that there was, in fact, a conspiracy between the Prime Minister, the Archbishop of Canterbury, and all the Members of Parliament to influence publishers against him. The questions of the two doctors had been such as would arouse the suspicions and rage of any man. He had fought for his liberty. Dr. Phipps had visited the house on many occasions when not required professionally, and had also been seen examining the rings at Woolworth's. The poet's household was maintained on his sister's private fortune, not on the revenue from his works.

Cross-examined by Mr. R. O'Sullivan, of the Middle Temple, counsel for the defendants, Mr. Postlethwaite said that he had at times read his poems to his sister, the cook, and the gardener. He did not agree that he had bribed them to listen; on occasions, when exhausted with the fire of declamation, he had refreshed himself with the gardener in the summer-house. The form of refreshment was gin. He took gin to assist him with his work. He worked a great deal. He had been attended by Dr. Phipps for gastritis, whether attributed to a bout of gin he could not say.

Miss Lottie Postlethwaite substantiated the facts of the case. She had sent for Dr. Phipps to see if anything could be done for her brother's fits of temper, because the cook had complained, and she did not wish to lose her. Geniuses were common, but cooks were not so common. She did not believe her brother had ever been insane at all. She was quite positive that there was a conspiracy, as he stated, to prevent the publication of his poems. She had not read any of them herself, but her brother had read them to her frequently. She admitted to 49 summers. Dr. Phipps had repeatedly proposed to her during the last nine months, and she had refused him. She had allowed herself to be guided by the specialist in signing the Urgency Order, but had refused to sign another Order at the end of the week.

Dr. Sigmund Waterman said that the patient had not been fit for examination before June 8th; such violence as he had shown in the asylum was consistent with the effects of hyoscine. There was no evidence that he had ever been insane. Cross-examined, he admitted that he was an admirer of the plaintiff's poems, and wished he would write some more.

The next witness, on being asked if he were the Rev. Josiah Pentwhistle, replied in the negative, and stated that he was a reincarnation of the prophet Isaiah. Counsel requested his lordship's ruling as to whether the evidence were relevant, as the individual appeared to be one over whom the Court could have no jurisdiction. His lordship admitted the point, but said he was loth to disallow the evidence as it promised to be interesting. The witness then deposed that he was a minister of the Fire Baptists. The doctrine of this body included the belief that every member of the sect was the reincarnation of some historical personage, and each aspirant to membership was required to appear in a public place with a bucket of boiling brandy on his head. The brandy subsequently became the property of the clergy. He did not himself write poetry, but might at times inspire it.

Evidence for the Defence.

The counsel for the defence submitted that there was no case at all against Dr. Phipps, since he had signed no paper, and asked for his lordship's ruling. Counsel for the plaintiff said that the case against Dr. Phipps was one of conspiracy, and hence the act of one was the act of both. His lordship thought it was better to allow the question to go to the jury. Mr. O'Sullivan continued the case for the defence by saying that it was based on Section 330 of the Lunacy Act, which protected medical practitioners from damages provided they had acted in good faith and with reasonable care.

Dr. Phipps deposed that he had attended plaintiff off and on for three years, and on one occasion for an attack of gastritis due to a bout of gin. He had thrown things at the cook before.

(In answer to a question by his Lordship: The same cook.)

Examination continued: There was no conspiracy between him and Miss Postlethwaite; she had never been asked to marry him. He had never inspected diamond rings at Woolworth's. His visits to plaintiff's house had been purely professional. He drew attention to his age, which was 29. He agreed with counsel that Miss Postlethwaite's belief in his ardour might be a delusion, and that delusions ran in families.

A Juryman: "Did you put any irritating questions?"

Dr. Phipps: "I examined him with regard to his mentality. He was certainly irritated."

Dr. Dementius Precox, on being asked if he were the celebrated alienist, replied, "I have made a special study of psychiatry." He would define delusional insanity as "a condition of mental disorder characterised by delusions." Violence was not an essential feature of it. He had made an entirely independent examination of the plaintiff, and had exercised the tact for which, he thought, he was well known. He regarded him as a danger to the household. He did not regard failure to secure publication of poetical works as a sign of insanity; nor would he so regard success.

Mrs. Flora Macdonald denied slamming the door, but admitted opening the window, and confirmed the remaining facts as far as they concerned herself.

Verdict.

His lordship, addressing the jury, outlined the working of the "Urgency Order" and the importance of invoking it only in cases of real emergency. He felt it his duty to inform them that he did not consider there was any case against Dr. Phipps.

The jury, after a brief discussion, found for the defendants.

Mr. Arthur Cheatle, President of the Listerian Society, thanked the Lord Chancellor for taking part in the proceedings.

Mr. Frederick William Salter, of Brough, Yorks, left, among other bequests, £500 to the Hull Royal Infirmary and £1000 (if his estate will admit of it after paying all other legacies) to the British Empire Cancer Campaign, 19, Berkeley-street, London, W. (or if his residuary estate shall not amount to such sum any balance up to that sum).

THE MOTOR SHOW.

DOCTORS who are having trouble with motor spirit are advised, when at the motor show, to take the opportunity of discussing the matter with representatives of the British Petroleum Co. (the Anglo-Persian Oil Co.). They should also visit Duckham's stall. Duckham's new process oil is an entirely new departure in lubricant distillation and has heat-resisting properties possessed by no other oil on the market. A special brand at a lower price is marketed for Trojans. Finally, the doctor who is considering the replacement of tyres should inspect the cord tyres shown by Messrs. Dunlop.

CIVIC HEALTH WEEK.

Two booklets, issued by the public health departments of large urban areas, are good examples of the advantage being taken by the sanitary service of using Health Week as an opportunity to preach the gospel of healthy living.

St. Pancras celebrated Health Week from Oct. 3rd to 9th. Dr. G. Sowden sets out to teach every member of every family, and expressly states that the booklet is intended to be kept and referred to all through the year. A number of the most common infectious diseases—measles, whooping cough, diphtheria, scarlet fever, tuberculosis, and summer diarrhœa—receive a page each of simple directions, not with any idea of enabling parents to dispense with the advice of a qualified doctor, but to help them to avoid serious mistakes and risks. Everything is stated in commendably short, simple sentences—e.g. :

Health is won by a way of life—not by a bottle of medicine.
Do not take a suspected case to the doctor or hospital or dispensary—if you do, other persons in the waiting-room may catch the disease.
Cold air is no more dangerous than cold water.

In Kingston-upon-Hull the most important feature of Health Week, held from Oct. 16th to 23rd, was a Health Exhibition in the City Hall, admission to which was by the booklet, at 1*d.* each. A large part of the exhibition was supplied by the Central Council for Infant and Child Welfare, with the organiser, Miss M. H. Keating, in charge. A message was broadcast by Dr. W. Allen Daley, M.O.H., health talks were given, plays were performed by school children, and no less than 25 different health films were shown. There were also open days for visits to various health institutions, public and private. The object of this booklet is, first, to interest people in the exhibition, a full programme of events being included, and, secondly, to bring home to the citizens of Hull all the facilities existing for their help. Short illustrated accounts are given of such items as the municipal maternity home, a maternity and child welfare centre, the sunlight clinic, the city laboratories, a school for physically defective children, the tuberculosis after-care colony, and many other provisions of the public health department.

A beginning has been made in Liverpool with what promises to be a useful development in the campaign for the more intelligent interest in and coöperation with the work of public health authorities on the part of the mass of the citizens. Taking advantage of the "Civic Week" celebrations, the medical officer of health organised a series of lantern slides demonstrating the manifold activities of the local sanitary officers, not only in those departments which touch the daily life of the man in the street, but also in those wider fields of international medicine which are of the utmost importance in the life of a great sea-port. There was also shown a collection of models illustrating the housing problem and the treatment of slums. The opportunity was taken, too, of demonstrating some of the child welfare branches of the medical officer's department.

Last week, under the auspices of the Women's National Health Association, a "Health Week" was held in Dublin, where a number of lectures dealing with various aspects of the public health were delivered at the several babies' clubs throughout the city. In connexion with the campaign, an address on "Voluntaryism in Health" was delivered to the Dublin Rotary Club by Mr. E. P. McCarron, Secretary of the Department of Local Government and Public Health. He said that the importance of domestic and general sanitation had become more clearly understood, and a noticeable improvement had taken place in general cleanliness. The mean average rate of infant mortality for the Irish Free State had come down from 82 per 1000 in 1914–18 to 69 per 1000 in 1925, a fall largely, if not mainly, referable to the beneficent activities of maternity and child welfare schemes and other educational agencies. Special attention had been paid by the department and by local authorities to the correction of deformities in children. In regard to milk, considerable improvement was noticeable in most districts; milk-borne epidemics of enteric fever, at one time of constant occurrence, were now practically unknown. The death-rate from non-pulmonary tuberculosis associated with infected milk showed a decrease of 47 per cent. since 1904. New cleansing methods had been introduced; dust and dirt were being rapidly eliminated; the domestic phase of electricity was being developed. Best of all, progress in housing had been greatly accelerated. The Local Government Act of last year had abolished the wasteful and ineffective rural sanitary units. In another address delivered later in the week, Mr. McCarron stated that medical inspection of school-children would be undertaken at once when the new county medical officers of health had been appointed. Deputy T. Hennessy, F.R.C.S.I., in an address dealing mainly with the milk-supply of Dublin, stated that the milk produced in Dublin itself was derived from first-rate cows, kept under good conditions, but there was no control over the production of the inferior milk that reached Dublin from outside.

PUBLIC HEALTH IN NYASALAND.

THE Protectorate is divided for administrative purposes into four provinces—the Zomba, Southern, Central, and Northern—each of which is in charge of a commissioner. The chief towns are Blantyre, Limbe (near Blantyre), and Zomba (the seat of the Government). At the end of 1924 the European population was estimated at 1462, the Asiatic at 669, and the native population at 1,210,344. The admissions of Europeans to hospital were 192 in 1925, as compared with 147 in the previous year, whilst 451 were attended as out-patients, as compared with 559 in 1924. There were 3539 natives admitted to hospital and 115,690 treated as out-patients, as against 2842 and 114,043 respectively in 1924. Two cases of sleeping sickness in natives were admitted to hospital and both died. There were no cases of plague reported, and only one case of small-pox. There were no serious epidemics during the year.

The climate of Nyasaland in its essential features is similar to that of the rest of Eastern Africa within the tropics. As a large proportion of the Protectorate lies at an altitude of 3000 ft. or more, the heat is not generally excessive. The monsoon commences to blow strongly in September, and the first rains may be expected any time after mid-October. From their commencement to the end of December it is usual to experience violent thunderstorms and heavy precipitation in a few hours, followed by an interval varying from 1 to 15 or 20 days of intense heat. With the return of the sun from its southern limit of declination, the thunder-storms diminish in intensity and frequency, and are replaced by steady rain—January, February, and March being usually the wettest months as regards duration of rainfall as well as actual amount. After March the frequency and intensity of rainfall diminish rapidly, and from May to September the climate is comparatively cool and dry.

INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED OCT. 16TH, 1926.

Notifications.—The following cases of infectious disease were notified during the week:—Small-pox, 132 (last week 121); scarlet fever, 1839; diphtheria, 1166; enteric fever 75; pneumonia, 744; puerperal fever, 51; puerperal pyrexia, 129; cerebro-spinal fever, 5; acute poliomyelitis 62; acute polio-encephalitis, 16; encephalitis lethargica 33; continued fever, 1; dysentery, 12; ophthalmia neonatorum, 143. There were no cases of cholera, plague or typhus fever notified during the week. The cases of poliomyelitis and polio-encephalitis are the subject of comment in an annotation. One case of small-pox was again reported from the London area, the remainder as before from the northern counties.

Deaths.—In the aggregate of great towns, including London, there was no death from small-pox, 1 (0) from enteric fever, 9 (0) from measles, 2 (0) from scarlet fever 16 (4) from whooping cough, 39 (13) from diphtheria, 171 (28) from diarrhœa and enteritis under 2 years, and 38 (6) from influenza. The figures in parentheses are those for London itself.

CIVIL VITAL STATISTICS.—The Registrar-General's Statistical Review, 1925, Tables, Part II., Civil (price 5*s.*), is now on sale at H.M. Stationery Office. The review estimates the population of England and Wales on June 30th, 1925, as 38,890,000 against 38,746,000 in 1924, an increase of 144,000. The births registered in the year 1925 totalled 710,582, representing a rate of 18·3 per 1000 population which was 0·5 per 1000 below the rate for 1924, and with the exception of the war years 1917–18 the lowest recorded. Excepting the war years 1917–19 the number of births is the lowest number registered in any year since 1861. The proportion of male to 1000 female births was 1045. This proportion showed a great increase during the war years and reached a maximum of 1060 in 1919, since when, with one exception, it has shown a continuous decline, but is still above the proportions recorded since 1860. The deaths numbered 472,841 and corresponded to a rate of 12·2 per 1000, the same as for the previous year, but 0·6 more than that for 1923, which was the lowest on record. The marriages registered in England and Wales during the year 1925 numbered 295,689, corresponding to a rate of 15·2 persons married per 1000 of the population, and show a decrease of 727 over 1924.

Bradshaw Lecture

ON THE

THEORY OF DIAGNOSIS.

Delivered before the Royal College of Physicians of London on Nov. 4th, 1926,

BY F. G. CROOKSHANK, M.D., F.R.C.P. LOND.,

PHYSICIAN TO THE PRINCE OF WALES'S GENERAL HOSPITAL AND TO THE FRENCH HOSPITAL AND DISPENSARY; CONSULTING PHYSICIAN, NEW END HOSPITAL, LONDON.

Verumtamen praesentium cognitium proprie nomine *diagnosin*, hoc est dignotium, appellare consuevimus.
—*Galen* (18–2–24).

PART I.

MR. PRESIDENT, FELLOWS OF THE COLLEGE, LADIES AND GENTLEMEN,—My first duty is to acknowledge the responsibility, cast upon me by your late President, of commemorating the professional and domestic virtues of him whose sorrowful relict became, in 1880, our eponymous benefactrix. This responsibility is, however, not unmixed with gratification, for I succeed, *sed longo intervallo*, one whose memory should still be green within these walls—Dr. Vivian Poore who, in 1881, gave here the first Bradshaw lecture.

Amongst the Fellows of this College there have been not few more learned in the history of our art and of our science; there have been others more nicely versed in the subtleties of some narrow specialism; and there have been many who have commanded greater recognition. But they have not been many who have better earned the right to be called *Physician;* one whose practice is broadly based upon an intimate acquaintance with Nature, the kind parent of all things. His humanity, his wit, and his sagacity, were gifts not often possessed in such measure by those who obtain greater immediate reward but perhaps exert less lasting influence. I am grateful for the opportunity of saying how much I owe to him.

MEDICINE AND SCIENCE.

By the terms of the Bradshaw Trust, the subject of this lecture must be connected with medicine or surgery; and I have chosen for my theme the Theory of Diagnosis, believing that none other can be more proper either to medicine or to that part thereof we call surgery. Indeed, to diagnosis even therapeusis must yield pride of place, for, in the quaint words of Hart, written in 1625, ancient physicians "did . . . divide Physicke principally into two parts, to wit, that which we commonly call Therapeuticke . . . and that part which we call Diagnosticke, whose most common scope is to discerne the whole and sound from the like and the sick and infirme from the whole, being unlike the one to the other. And this part of Physicke doth farre excell the other, to wit, the Therapeuticke, the which without the Diagnosticke is of small use and profit."

Formerly, the greatest masters of scientific method—as Harvey himself—were accustomed to interpret their observations in the light of those fundamental principles that make up the very matrix in which all true sciences are formed. But the separation between philosophy and natural science that marked the close of last century became so wide that, although reaction has set in, and many are now eager to discuss the general validity of scientific conclusions, medical men are still prone to assert that medicine as a science stands, and must ever stand, upon a so-called solid base of observed fact and planned experiment, in complete dissociation from all mental discipline as such. It is in sympathy with this attitude towards inquiry into the mental processes by which we obtain our "facts" that all trace of metaphysics, logic, and philosophy has disappeared from medical education since, in becoming more medical, it became less educative. Profoundly dissatisfied, Dr. Mercier wrote, ten years ago, that, while the fundamental concepts in every calling are the most difficult to define, and the definition of them is not arrived at until late in the history of that calling, nevertheless in every calling a time must at length arrive when such definition is needed, and that such a time is now arrived in the history of medicine. Now medicine, so far as itself a science, is (as Hobson says natural science is in its every stage and its every department) a conceptual scheme and not a perceptual intuition. The need for clear definition of the integral concepts of medicine is, therefore, at least as imperative as is the practice of that indirect or analogical form of observation by experiment, which to so many seems to afford a more solid "basis of fact" than does direct observation at the bedside or in the field.

It is necessary to insist upon the conceptual aspect of medicine as a science, for—again to quote Hobson—in modern times until recently most men of science have been dominated by the philosophical theory of knowledge—essentially unnecessary to scientific method—known as physical realism. The influence of this theory is never more prejudicial than when unconsciously sustained by those who loudly proclaim the freedom of medicine from philosophical thrall!

No further excuse seems needed for an attempt to say what we have in mind when we speak about "this so noble a part of Physicke" and to give an account of its theory—that is to say, to explain it, by appeal to first principles in terms that are independent of medical doctrine. But if success is to be obtained—and by success I mean not finality but the clarification of thought—we must give ear to Galen and "come to agreement quickly about Words, getting soon to the Things themselves, and spending on these only our time and trouble, for most of those who call themselves educated do otherwise, and so do never perfect their Art." (7–43, 44.)

Important though it be to distinguish between words and things, it is no less so to distinguish between the words by which we tell our thoughts about things: these thoughts, and the things that are thought about. This triple distinction between what I have called names, notions, and happenings—or, as Messrs. Ogden and Richards say, perhaps with greater propriety, words, thoughts, and things—should be maintained during every discussion. We should, therefore, think separately of *diagnosis*, the name, or verbal symbol: of the notions for which this symbol has stood, and the explanations thereof; and of the processes concerning which these notions and explanations have been entertained. In so doing we follow the injunction of William of Occam, the greatest of English philosophers, and choose always the *suppositio* beneath the word; whether the word be employed physically, or *materialiter*, *pro voce;* conceptually, or *simpliciter*, *pro intentionae animae;* representatively, or *personaliter*, *pro re*. This is what Ogden and Richards intend when they speak of the word or symbol, standing for a mental *reference*, which itself represents the *referents* we observe or think about.

DIAGNOSIS: THE NAME.

The Greek word *diagnosis*, with its congeners, is infrequent in the Hippocratic Collection, though less so than may be thought, since some translators have avoided the use of exact equivalents, apparently because the full Greek meaning is not always conveyed by them. Recourse has been had to periphrasis; and the suggestion that the modern English usage of the word is not that of the Greek has been avoided. Without doubt Dr. Withington—to whom I am more than indebted—is right when he says that, in the Greek, the connotation of the particle *dia-* in *diagnosis* is at least as intensive as discriminative; his view is supported by the fact that though no formal definition of the word appears in Hippocrates, Galen, in whose writings it is exceedingly common, does define it (in the "Commentary upon the Prognostics of Hippocrates") as the clear cognition, or *gnosis*, of things present (18–2–24). So, too, when he declares that it took him long to make the fundamental *diagnosis* of the pulse—that the artery not merely rises and falls, but expands (8–771). Later writers seem to have used the word mainly in copying from

Galen and, although *dignoscere* is in Virgil, it is said not to occur in Salernitan translations or in mediæval writings generally. I have not seen it in any Latin work earlier than the last part of the sixteenth century, when its revival was probably due to renewed acquaintance with the Greek of Galen. (Withington.)

Diagnosticke we have seen as an English substantive in 1625 (Hart), but *diagnosis* does not occur till 1681, when Pordage, in the glossary to his translation of Willis, defines it as *dilucidation*, or *knowledge*. Later, the word does not appear to have been greatly used for nearly a hundred years, and then somewhat differently. In 1731 de Sauvages had attempted to classify diseases as if they were indeed objects or groups of objects in nature: in Sydenham's words, "to be reduc'd to certain and determinate kinds, with the same exactness as we see it done by botanic writers in their treatises of plants," and possessing "certain distinguishing signs which Nature has particularly affixed to every species." Faber has shown how Linne, fired with enthusiasm, applied to diseases his own aphorism, *Species tot sunt diversae quot diversae formae ab initio sunt creatae*, and caused a "Genera Morborum" to be compiled for the use of his own pupils. The fashion spread, and in 1771 a new era in modern medicine commenced when Hélian published his "Dictionnaire du Diagnostic, ou l'art de connaître les maladies et de les distinguer exactement les unes des autres."

Now whatever we may hold a *species* or *genus* to be, no disease is a discrete object of perceptual experience in the way that a single plant is, and, while much may be said on grounds of convenience for classifying the various kinds of illness we recognise, the implication that *diseases* are species of classifiable entities and that the art of diagnosis only came into existence after their recognition as such, is a consequence of our failure to follow Harvey's example and to inquire, with Aristotle, whence and how knowledge reaches us. Moreover, we cannot accept the identification of a process with one of its own modalities as a definition of that process. Now although Cullen in 1772 introduced into Scotland a systematic nosology based upon symptom-complexes, and Price in 1791 published in London a "Treatise on the Diagnosis and Prognosis of Disease," or, as Forbes gives it, *Diseases*, English physicians, on the whole, long regarded diagnosis as a process applicable to persons rather than to diseases, and displayed little enthusiasm for the botanical classifications of de Sauvages and his followers and the specifist doctrines of the later French Organicists headed by Bretonneau and Laënnec. Nevertheless, in Forbes's translation of the latter's famous "Traité" (1834) we find such a phrase as "the diagnosis . . . . of pneumonia," and the advantages of classifying clinical phenomena and creating diseases by the correlation of sign-groups with post-mortem patterns, in the style of Laënnec, became so appreciated that for many years to interpret in terms of specific diseases was almost the only duty of the diagnostician. Thus, in 1882, the New Sydenham Society's "Lexicon" laid it down that diagnosis is the distinguishing of things, the noting of symptoms, whereby a disease or plant *or other object* may be known for what (it) is and not another. The following year Hecht, in the "Dictionnaire Encyclopédique des Sciences Médicales," defined diagnosis as "cette partie de la pathologie qui a pour objet la distinction des maladies entre elles," a definition persisting so lately as 1904 in Dunglison's "Dictionary of Medical Science," which states diagnosis to be that part of medicine whose object is the recognition or determination of the nature of diseases and the knowledge of the pathognomonic signs of each. By the "New English Dictionary" diagnosis, in the medical sense, is said to be the determination of the nature of a diseased condition, or the identification of a disease by careful investigation of its symptoms and history, together with the opinion, formally stated, resulting from such investigation. The same dictionary gives the general, or biological meaning as "distinctive characterisation in precise terms." That it is characterisation that is of the essence rather than characterisation in terms of any particular convention is implied by Dr. Christian when, in the "Oxford Medicine," he writes that diagnosis depends upon a proper evaluation of signs and symptoms recorded by all available means and interpreted with the critical judgment of a large common sense.

Thus do we return to Galen's definition of diagnosis as the clear cognition of things present, and to the right to employ, without doctrinal or conventional prejudice, this word which, first used by the Father of Medicine, has been absent from literature during long periods of time, and to-day is more than ever conspicuous in our verbal equipment.

DIAGNOSIS: THE EXPLANATIONS.

It is disappointing to the student of medicine to find during the last 150 years—a period coterminous with what Singer calls the Reign of Law—so easy an acceptance of linguistic subterfuges which, however convenient when teaching students, are yet responsible for much confusion in the minds of students grown to be teachers.

In former days the physician brought to medicine a mind trained in the theory of knowledge: like Galen and Locke, he made contributions thereto. Diagnosis was then the application to the field of medicine of a method of thought already learned. So, when in the sixteenth century such physicians as Fernel discussed the first principles of all science in their Institutes of Medicine, the theory of diagnosis flowed naturally therefrom and called for no separate discussion.

In the nineteenth century the case was altered. Together with a distrust of logic and philosophy, and a strange belief that science alone gave a sure foothold, there grew up a desire to contain medicine within a cincture, and to-day many a student obtains no better idea of diagnosis than that it is what we do when we encounter a disease: and of a disease, than that it is the sort of thing we diagnose when we encounter it.

Of course, so long as Sydenham's pleasant fancy was accepted as a premise—and it was believed that there are in Nature objective and real, even if immaterial, entities called diseases, denoted by fixed characters and, *ex hypothesi*, the proper subject of diagnostic studies—for so long was it impossible to define diagnosis otherwise than as the art of distinguishing between them. This premise is even yet not decisively repudiated, but, unfortunately, when the nosological systems still perpetuated in our "Official Nomenclature of Diseases" first became rife, those who, like Jeremy Bentham then combated the errors of physical or scholastic realism, had not sufficient technical interest to develop the application of their arguments to medicine, whilst Marshall Hall, in his book "On Diagnosis" (1817) merely said that the diagnosis of *diseases* constitutes the foundation of the practice of medicine, and such medical logicians as Lanza (1826) cared more to undertake medical research, as they called it, by ratiocination than to discuss so humdrum a process as diagnosis appeared to be.

Even Oesterlen, of Heidelberg, whose "Medical Logic," translated by Whitley in 1865, ably exposes the vice of treating names of diseases as if representing existent objects, finding diagnosis fallen amongst thieves, passed by upon the other side and spent energy in a laboured attempt to torture medicine into compliance with the Procrustean demands of Mill's Science of Inductive Logic, or Inductive Philosophy, as it was called. Perhaps in medicine we still tend to use the word *induction* emotively rather than intelligently, and without any clear logical connotation!

At any rate, Barclay, who, in his "Medical Errors" (1864), spoke of the "positive induction that forms one of the elements of the deductive argument by which we arrive at the true diagnosis of disease," tried hard, in his "Manual of Diagnosis" (1857–70), to analyse diagnosis in terms of the prevailing logic, and suggested that the best method of teaching it

was to lay down rules whereby the student might distinguish the diseases described to him in the schools. He never questioned the adequacy of the heroic attempt to resume or group all clinical phenomena in terms of diseases only, or the permanent validity of the nosological distinctions in vogue at the time of the Great Exhibition. Still less did he appreciate the exercise of the diagnostic art by the greatest physicians of all time long before the promulgation of these distinctions, and we receive, in some sort, the impression of an excellent photographer of the period who, writing about Art, ignores the efforts of Phidias and Leonardo in their regrettable lack of acquaintance with the technique of the carte-de-visite and the dry plate.

The truth is that Barclay, whose text-book long remained deservedly popular, had no inkling of the scholastic doctrine of *ficta*, revived in these latter days to teach us that the primary concepts of the physical sciences are subjective interpretations, justified by their convenience and the measure of common assent that they may obtain, but not as perceptions of reality. And so, again girdling medicine with her own zone, he explained diagnosis as the application to any particular case of the lessons taught by semiology and nosology; much as we might define literature as the application to a particular theme of the lessons taught us by caligraphy, dactylography, stenography, and typography!

The professed logicians were not more happy than the logical doctors in their dealings with this subject. Bain (1870), like others, ignored routine diagnosis and, whilst condemning realism in the scholastics, showed himself, like many philosophers, a realist in medicine, giving rules for the naming of diseases which (he said) are generally localised in separate organs or tissues. To Jevons (1877) diagnosis was the operation of discovering to which class of a system a certain case or specimen belongs, an operation performed by the serial rejection of the infinite classes with which the case does not agree. We still do nominal honour to this scholastic operation implying the reality of classes, when we speak of diagnosis by exclusion; but Jevons did not care to examine what generally happens. He set out what people would have to do in order that logicians might say they were behaving in the way they ought to do. And he ended by believing that they did so.

For many years after Jevons the question was not reopened. But, since the South African War, many books have been written professedly devoted to diagnosis as the most important part of medicine. These books give excellent schemes for the physical examination of the patient, whilst strangely ignoring, almost completely, the psychical. The materials are arranged semiologically or topographically rather than nosographically, and all allusion to therapeutics is foregone. But they agree with text-books of medicine generally in avoiding all discussion of first principles, and, so far as possible, any attempt to define disease or diseases, and any hint that the nosological convention represents only one method of diagnosis. Such attempts as are made to define diagnosis are usually either descriptive or involve an obvious *circulus in definiendo*. Thus, one author tells us that diagnosis is prerequisite to accurate prognosis and effective treatment, so that the true end and aim must be the earliest possible recognition of any disease (1922); a second, that diagnosis is the method of distinguishing from one another diseases that have symptoms more or less alike (1925); a third, that a correct and integral diagnosis is the *sine qua non* of rational therapeutics and one that conforms to reality, as shown by the evolution of the malady, the success of the treatment, and the findings at the necropsy!

However, three determined efforts have been lately made to grapple with the subject, and all hail from North America. Dr. Stanley Ryerson gives a clear method of case-taking, but attempts once more to explain diagnosis in terms of inductive logic. Yet, since Mill himself defined induction as the process by which what is true at certain times or of certain individuals, is inferred to be true in like circumstances at all times or of a whole class, it is difficult to see how diagnosis can be said to be an induction or an inference from known particulars to an unknown general. There is a better logical case for speaking of diagnosis as *deductive* for frequently, though quite wrongly, some diagnosticians persist in inference from an assumed general to a present particular! Dr. Llewellys Barker, in the "Oxford Medicine," says rightly that in bygone days there was, as now, recognition by only a few that groupings of signs of illness are conceptual and to be changed when the purpose changes. But we feel the ghostly presence of the Victorian realists and logicians as we turn Dr. Barker's many informative pages and trace the steps we are told we take, or ought to take, when we tread the path of diagnosis.

We learn to distinguish the philosophy, the science, and the art of diagnosis, and are told that, in the application of the science to the art, there being recognition of a problem to be solved and a feeling of diagnostic difficulty, data are accumulated, the anamnesis is recorded, and the *status praesens* investigated, while the catamnesis and epicrisis are duly noted so that, data being summarised and arranged, diagnostic suggestions are considered and, hypothesis not being undervalued, fundamental relations are thought of and elaboration by reasoning, submitted to testing, is guided towards the end. But what is this end—the final cause, in Aristotelian phrase—of diagnosis? It would almost seem, from what Dr. Barker tells us, that diagnosis is the function we discharge when, a diagnostic difficulty being felt, we decide between diagnostic suggestions in order that we arrive at diagnostic conclusions—a solution reminiscent of Raymond Lully when he said that the digestion is the form by virtue of which the digestive digests the digestible!

Dr. Warren T. Vaughan very nearly hits the mark when, in a modest essay that avoids all sophistication, he compares the act of diagnosis to a detective enterprise. For the detective, employing no formal logic or scheme, reasons as does every man in every hour of his life; making use of his acquired knowledge and experience, he interprets what he observes by means of his commonsense. But this is what Dr. Christian says the diagnostician does. In other words, and if we may talk of faculties, the detective and the physician alike exercise what Sturt calls some common constructive or reconstructive faculty and do *not* adopt any of the rationalised methods that logicians and novelists say they do.

In Rignano's language play is given to two fundamental activities—the one intellectual, the other affective. Images of the past are evoked by the present, and the mind seeks the satisfaction that is attained when a judgment that well serves our purpose is achieved. More simply still, diagnosis is just the first stage of the physician's work, the process of forming and expressing those judgments concerning the present state of the sick that guide us in our office of healing; and it consists in observation of the sick, interpretation of what is observed, and symbolisation of the interpretations accomplished.

DIAGNOSIS: THE PROCESS.

Thus considered, diagnosis ceases to be an esoteric process for finding out "what is really the matter." We do not confuse it with any particular diagnostic convention, or assume that they who do not diagnose as we do do not diagnose. We appreciate that it is not governed by strict rules or comparable to the identification of a postage stamp by reference to a collector's catalogue. Finally, we proceed to investigate diagnosis by the methods of psychology, recognising that, like logic, it is a matter for psychologists rather than for the logicians who have so dismally failed us at their own business. This being so, we come to regard diagnosis as a kind of reflex process which, regarded subjectively, resolves into three members, whereof one is perceptive or observational, another associational or interpretative, and the third efferent or symbolising. Thus every response to injury becomes at once a reflex and a diagnosis;

and the reparative process, once regarded as something put forward by a *vis medicatrix Naturae*, is better understood as the effective symbolisation by the organism of the cognisance that it takes of the lesion. The salamander who, its tail being removed, sets about and grows a new one, and the cat, who, feeling ill, seeks and finds the grass that cures, both make diagnoses that may be instinctive but are perfectly adequate to the occasion! The surgeon may reply that one salamander cannot grow a new tail for another, and the salamander may retort that the surgeon cannot grow a new leg even for himself! Still, both salamander and surgeon, like all living creatures, exercise diagnosis in their own measure and according to their own opportunities!

Moreover, Signorina Locatelli has lately shown that the reparative powers possessed by newts are exerted through the nervous system in such fashion that we have to reckon with not only a generalised tendency to repair, possessed by every tissue and by every cell —whereof (as Prof. Leathes has recently said) the persistence is by definition required for the very maintenance of living existence—but a specialised regional reflex system which, for some creatures, assures the reproduction even of a limb. May we not inquire, then, if some healers, even though "unqualified," do not possess some instinctive diagnostic and healing faculty that finds expression practically rather than verbally, but *for others*; a faculty analogous to the instinctive mathematical gifts of the strange calculating boys? At any rate, the observable diagnostic series seems to extend, with gradual transition, from the so-called instinctive and selfish processes of the lower animals to the highly rationalised, and, of course, altruistic judgment-formations of the medico-legal expert, so that the only convenient criterion, restraining the word diagnosis to forms of human endeavour, is that of verbal expression or symbolisation. We are, then, burdened with the task of distinguishing between rational and irrational or—what is not the same thing—orthodox and unorthodox symbolisations.

However, recognition of this evolutionary aspect of diagnosis—stressed by Martinet when he said that "les degrés divers actuellement réalisés par la science diagnostique reproduisent les étapes mêmes de l'évolution diagnostique au cours des âges"—carries with it an obligation to undertake comparative studies that has been insisted upon by Masson-Oursel, though it was Rivers who first pointed out that some primitives practise an art of medicine more rational than ours, in that their modes of diagnosis flow more directly from their ideas concerning disease.

It is, at first, shocking to be told that diagnosis may be at least as rational and as practical when stated in terms of demons as in terms of diseases, yet a dose of castor oil is indifferently efficacious whether a demon or a disease be held responsible for the symptoms, while there is a closer affinity than may be thought between those who believe in specific demons and those who talk about the specific clinical entities that "attack the human race." It is certainly remarkable that, at the stage of human progress when, as Bordeu said, a natural medicine is practised that is comparable to natural religion, there should be clearly marked two diagnostic trends that are traceable throughout the whole history of medicine and that persist to-day amongst us.

Rivers found, diffused throughout America, Indonesia and Papuo-Melanesia, the notion that disease is an abstraction or loss of the soul, or vital principle, or a part thereof; in India and in Africa the belief that disease is due to a something added—a spirit or a demon. Clearly we have here a hint, and more, of the secular controversy between those who find in disease an impairment or failure of functional activity or adaptation—the Vitalists, who regard disease as an accident or *aliquid entis*—and the Organicists, who explain all disease worth their attention in terms of physical attack on organs, and consider each described disease to be an entity, or *ens*. This controversy is indicative of a dichotomy that has ever vexed medicine since first practised (as we say, rationally) some 2400 years ago—a dichotomy that has sometimes seemed best indicated in terms of practice, sometimes in those of doctrine, and again in those of philosophy.

Sometimes, perhaps, the difference has been obscured by the apparent inconsistencies of the greatest physicians who, like Galen and Sydenham, have seen something of the truth in each side, have attempted to reconcile the contending opposites, and have been claimed by each party in turn. But always the difference has been one that is best *stated* as a difference in *method* of diagnosis—that is, in observation, interpretation, and symbolisation—and is best *comprehended* as dependent upon fundamental psychological divergences.

These divergences are of more than medical interest, for in some sort they affect all mankind. They are allied to those which separate the romantics and classics of literature, and, perhaps, also Ostwald's romantics and classics of science, as well as the introverts and extraverts of Jung; they are, perhaps, those which Coleridge had in mind when he said all men are either Aristotelians or Platonists, and which architects divine between the Gothic designers who build from within outwards and the classics who plan from without inwards. That such divergences should obtain in medicine is only to say that physicians are as other men; but that laymen are likewise divided in respect of diagnostic outlook was well shown, a few years ago, during the course of public discussion concerning the alleged diagnostic inefficiency of doctors!

Mr. G. B. Shaw then declared that diagnosis is not the mere affixing of a nominal label, but the finding out all there is the matter with a patient and why; the editor of the *Westminster Gazette* pleaded eagerly for the establishment of a diagnostic caste, whereof the duty should be to affix the proper label and pass the patient on to him who should treat the disease nominated. Herein Mr. Shaw ranged himself definitely with the Vitalists—best represented for us by the tradition of Cos: his colleague as definitely set himself amongst the Organicists of Cnidus—the spiritual home of all who manifest exact nosological proclivities and diagnose diseases rather than patients.

The elderly practitioner who, remote from libraries and from laboratories but near to Nature, is hesitant when asked for verbal diagnosis in terms of recent convention, yet clear in action, is in like fashion opposed to his more formal colleague who, diligently making a diagnosis in strict accordance with differential tables and tests, searches his text-books in confusion for the treatment appropriate to the disease he suspects. Wherein lies the fundamental difference between these two diagnostic attitudes?

All men, when about to interpret what is presented in consciousness, proceed in one of two ways. Some interpret the present by reference to images of past experience stored simply as memories, or as composites of like memories. Others compare present perceptions with mental constructs, made up of memories of like past experiences, but *colligated* (in Whewell's phrase) by something predicated, abstracted, or imagined which, linking them together, converts mere aggregates or composites into organised units that we call ideals, general terms, or universals—just as a colligating staff transforms a thousand men into a battalion. Herein is the difference between the two types of diagnostician —a difference that carries with it many correlations but corresponds closely to what Mr. Trotter has lately recognised as that between the direct or concrete and the indirect or abstract methods of thought.

The simple composites of *natural* diagnosticians—for whom the definition of diagnosis as clear cognition will suffice—are the *syndromes* of the post-Hippocratic empirics; as Hart said, nothing else but the collection of certain *accidents* and *circumstances* of disease. The mental constructs of *conventional* diagnosticians—for whom diagnosis must establish correspondence between the illness of each patient and some rationalised type —are, as a rule, diseases, but may be demons.

(The bibliography to Part I. will be given with Part II. in the next issue of THE LANCET.)

Thomas Vicary Lecture

ON THE

SIGNIFICANCE OF ANATOMY.

Delivered at the Royal College of Surgeons of England on Nov. 4th, 1926,

BY G. ELLIOT SMITH, M.D., F.R.C.P., F.R.S.,

PROFESSOR OF ANATOMY IN THE UNIVERSITY OF LONDON.

IT may seem strange that in this Museum where the Hunterian Collection is housed I should discuss such a subject as the significance of anatomy, the scientific and practical value of which as the essential foundation of surgery John Hunter surely established once and for all. But no one who is familiar with the attitude towards morphology which is widespread at the present time can doubt that there is need for an appreciation of the part the study of anatomy has played in the history not only of biology and medicine but also of civilisation as a whole, and the even greater services it still remains for the morphologist to achieve.

At the present time it is not only the physiologists and clinicians who question the value of morphology, but some anatomists also and even more biologists bow the knee to the strange fashion of depreciation. In some famous medical schools it is considered almost an offence on the part of an anatomist or biologist to devote himself to the essential business of his subject, and work at real anatomy. The interest and importance of experimental embryology and the fascination of this method of interrogating the processes of Nature are unquestionable. But even the fullest recognition of the value of such work and of the brilliance of its pioneers does not lend any sort of justification for the strange assumption that anatomists who devote their attention to other no less important parts of their subject are wasting their time to obsolete diversions.

The true history of this phase has been so correctly diagnosed by Prof. H. S. Jennings, of the Johns Hopkins University, that I make no apology for quoting him. Referring in *Science* (July 30th, 1926, p. 98) to anatomy as the "physics of organism," he said:—

> "It requires separate consideration, both because of its extreme importance for zoological experiment; and because it was minimised, nay, despised and rejected of the physiological impulse in zoology. This is the rôle of physical arrangements of material in organisms; gross physical arrangements as well as minuter ones; what is variously called organisation or structure. Structure had become the object of one of those epidemic phobias that beset scientific men as they do other men. In the days before experimentation, zoologists had given a romantic and mystical turn to the phenomena of structure in organisms; they built upon it a great edifice which was called morphology. They discovered in organic structure plans, styles comparable to the diverse styles of architecture; to Gothic, Romanesque, Classical, and the rest. But the physiologists said: This may be pretty, but is it Science? It is not. Out with it. We shall have nothing to do with morphology; it is fantastical. And throwing away the baby with the bath water, they largely rejected also the rôle of structural arrangements, even in experimentation. This it was that led to most of the adventures or misadventures of the sort I have recounted, in the progress of experimental zoology. It is important that this phobia should no longer dominate our work. Consider for a few moments the rôle of arrangements or organisation in experimental work, and the consequences of its neglect.
>
> Structural arrangements, organisation, is, of course, physics; we find it playing a very great rôle in physics as that science advances. The properties of atoms depend upon the arrangement of electrons, of molecules on the arrangement of atoms, of crystals on the arrangement of molecules. In organisms there is a great extension of this. They are bodies in which the arrangements have become complex and differentiated, and have passed into the grosser, the visible features as well as in the finer details. They are bodies in which there is an almost infinite variety of these arrangements, as we pass from species to species. They are systems of structures. In consequence their properties and the way they respond to experiments depend largely on these systems."

This address so admirably explains the real significance of morphology as the foundation of all science, physical as well as biological, that it is hardly necessary for me to add to it. In particular he has shown how many veins of experimental research have petered out. Many of the problems were suggested by morphological considerations and most of the results do not attain conclusiveness until they find confirmation from anatomical evidence. For example, Sir Charles Sherrington's definition of reflex action, the summary of an extensive chapter of physiological experimentation, is expressed in terms of the structures involved. The disparagement of anatomy extends also to morbid anatomy, and at the present time in many schools, with a few conspicuous exceptions, medicine and surgery are suffering from the neglect of adequate morphological tests of the reasons for diagnostic and therapeutic failures.

The eponymous label attached to this lectureship is not without interest. Thomas Vicary was the court surgeon of the Tudor kings and queens, and he left behind him an obsolete treatise on scholastic anatomy, based upon the writings of Lanfranchi and Mondeville in the fourteenth century, which completely ignored the revolution that had been effected in the whole outlook and discipline of anatomy by Vesalius 20 years before Vicary's death. Like Thomas Vicary, the anatomist at the present day has retained in his teaching an undue amount of mediæval method and material that has no justification either on the ground of its practical or scientific value. In paying respect to these antiquated conventions—the writings of earlier bookmen rather than what the human body itself reveals—he has neglected the great opportunity of bringing the subject of anatomy into closer corelation with the needs of the times. In spite of the century-old complaint that there is nothing more to be done in anatomy—as Barclay said in the eighteenth century: Anatomists are like geese picking up the stray grains left by former reapers—the possibilities for great achievements in anatomy were never so great as they are to-day; and the need for men who will devote their whole time and energies to the exploitation of these rich veins of ore was never so urgent as it now is in England. It was a great step forward when a generation ago men were appointed to devote their whole time to research and teaching in anatomy. The problems to be solved are so complex and the technique of inquiry so exacting that those who work at the subject must be wholly absorbed in it.

[After summarily describing the development and course of anatomical study from the Ptolemaic School of Alexandria to Galen, Prof. Elliot Smith referred to the special influence of the work of such anatomists as Harvey, Sharpey, and John Hunter. He continued:—]

The late Mr. Stephen Paget refers to the work of William and John Hunter on the lymphatic system as a new truth of vast importance, second only to Harvey's discovery of the circulation of the blood; and in estimating its significance he uses the words so many writers have applied to Harvey's achievement: "It changed the whole character of medical science and practice." That the lacteals, which carry food-products into the blood, were absorbent vessels, men knew already; but they had not realised that the whole body, every organ and tissue of it, is penetrated and drained by a special system of vessels to bring the fluids in the tissues back into the

blood stream. It is not necessary for me to say anything to impress upon this audience the importance of the lymphatic system in surgery and the value of the pioneer work of the Hunter brothers. A vast amount of detailed work on the lymphatic vessels and glands has been accomplished in recent years and valuable light has been shed, especially by our American colleagues, upon their developmental history. But the satisfactory solution of the controversies that have arisen as to the interpretation of the meaning of these observations will not be attained until we return to comparative methods and study the phylogeny rather than the mere ontogeny of the system.

The brilliant research on the lymphatic system of *Lophius* that has recently been accomplished in this Museum by the Physiological Curator, Mr. Richard H. Burne, is an encouraging sign that this great work is being carried on in its appropriate setting.

CHARLES DARWIN.

If Harvey introduced a new era in medicine and Hunter in surgery, Charles Darwin gave the whole world of learning a new outlook. The recognition of the reality of evolution effected a revolution not simply in biology, but in every field of intellectual work. Although Darwin's work was inspired primarily by what we now call nature studies, it is clear that the foundation of the argument, without which he would not have been able to convert people to accept his views, was represented by the facts of comparative anatomy and embryology. He himself says in the "Origin of Species" that morphology is the soul of natural history.

Darwin's achievement gave a new orientation and a new meaning to morphology. What is not generally recognised by physiologists at the present time is the vast scope of evolution and the significance of processes that took many millions of years to effect. They do not seem to appreciate that only an altogether insignificant fraction of the great natural processes is susceptible of experimental inquiry. When they ask what use can be assigned, say, to the morphology of the lizard's chondrocranium they thereby show a failure to appreciate that the great story of evolution is based upon the linking-up of the facts of morphology and palæontology. No full understanding of the behaviour of man or any experimental animal can ever be attained without a knowledge of his or its origin and evolution.

THE CELL THEORY.

What Prof. E. B. Wilson calls a milestone of modern scientific progress—the cell-theory enunciated by Scheiden and Schwann in 1838–39—stands forth as one of the greatest achievements in biology, which marked the beginning of a new era in knowledge and its application in practice. Goodsir, Virchow, and their successors used this conception for the analysis of the structure of organisms, and in doing so opened far-reaching vistas of progress in every department of biology and medicine. In more recent times the evidence afforded by the behaviour of chromosomes afforded anatomical corroboration of the results of experimental breeding and compelled even the geneticists to admit that morphology had its uses.

THE PRESENT POSITION OF ANATOMY.

Even if anatomy had achieved nothing more than make vital and essential contributions to the great revolutions in thought effected by William Harvey, John Hunter, William Sharpey, Rudolf Virchow, and Charles Darwin, its place in the forefront of progress would be established. But its claims are much wider than that. Its influence was, in fact, universally felt in the advance of civilisation. It is not, however, the place of anatomy in history with which I am chiefly concerned to-day. It is rather its present position and future development that I want to discuss. In your museum the word physiology is, significantly enough, used to connote comparative anatomy. This unusual usage expresses an important truth. For no method more clearly reveals the functions of structures than the correlation of their varying size and structure in animals of differing capabilities.

In his comparative study of the heart, and in particular of the bulbus cordis, the present conservator of the museum has shown, perhaps more clearly than in any other of his numerous works, that the spirit of John Hunter is still alive here. For the use of comparative anatomy, in conjunction with the study of the functional meaning of the varying arrangements, to illuminate the normal morphology and pathological states of the heart would have delighted the founder of the museum. Sir Arthur Keith's greatest service to science, however, has been his persistence in keeping constantly before the anatomist the urgent need for the study of function as an essential part of the interpretation of structure. From its foundation the principle has been emphasised in your museum. The use of the term "physiological series" for the collection of comparative anatomical preparations is a happy illustration of the real spirit of Hunter's work.

Take, for example, the case of the cerebellum, which I discussed in the Arris and Gale lectures in this room six years ago. Some physiologists (for example, Prof. Magnus in his Croonian lecture to the Royal Society this year) are now proclaiming that their experiments do not reveal any functions for the cerebellum; but anyone who walks through the gallery of this museum, where the wonderful collection of vertebrate brains is exhibited, can see for himself that Nature's great experiments in modes of posture and locomotion have left their impress so clearly in the cerebellum that he who runs may read. So also in the morphology of the brain as a whole the varying sizes and histological structure of its parts express the habits and capabilities of animals and reveal the broad lines of their functions.

In his great treatise on the "Integrative Action of the Nervous System," which opened a new era in the interpretation of the brain's meaning, Sir Charles Sherrington calls the cerebrum "the ganglion of the distance-receptors," by which are initiated and guided long series of reactions of the animal as a whole. Unfortunately he did not avail himself of the facts of comparative anatomy to elucidate and reap the full harvest of his illuminating idea. Here, again, it requires no difficult technical procedure or abstruse knowledge to discover facts of fundamental importance which have escaped those who neglect to give due consideration to comparative anatomy. It is only necessary to look at a comparative collection of brains such as this museum contains to see at a glance that the most primitive type of cerebrum is not equally the ganglion of all the distance-receptors, but predominantly the one concerned with smell. The part of the brain that eventually became the organ of mind is primarily a receptive centre for olfactory impressions, and the instrument whereby such experience can influence behaviour. The whole arrangement of the brain is dominated by this fact, which is fully borne out by experiments on the dog-fish, such as those of Prof. Parker, of Harvard University.

Considerations of structure cannot be ignored with impunity by those who aim at understanding function. After all the aim of experiment is to interpret the working of an instrument, and the mode of construction of that instrument cannot be neglected. But it is not only morphology that is essential, but also considerations of phylogeny, the relative place in nature and affinities of the experimental animal, the appreciation of which is based upon morphology. In all investigations considerations of evolution are matters of fundamental importance and are especially significant in the case of the nervous system, which undergoes profound changes in the course of its history. In such researches as those now being carried on by Prof. Magnus and his collaborators, the difference of behaviour in various grades of animals are being forced upon their attention. But the full fruits of much patient work are being lost by

many physiologists from their neglect of the phylogenetic factor.

THE NEW OUTLOOK IN ANATOMY.

As knowledge advances in physiology, pharmacology, biochemistry, and clinical medicine and surgery a host of new problems arise for the solution of which anatomy provides in many cases the means of solution and in all cases the coping-stone of objective demonstration and becomes the last court of appeal for its validity—the translation of elusive modes of reaction into the concrete terms of structure.

Experimental physiology aims at explaining the behaviour of living organisms and tissues, and if it is successful its results must be expressed in terms of the constitutions of the organism and its parts. Morphology is not only the foundation of experimental research—the territory in which the work is done and the study of the physical properties of the material investigated—but it also affords the ultimate test of the significance and validity of the results attained. Hence both kinds of investigation are essential and complementary the one to the other. The morphologist and the physiologist should work in close coöperation, the one with the other, and the clinician has opportunities for applying their results and making fresh observations suggesting new problems for the morphologist to investigate. How fruitful this coöperation of workers in the three fields can be is shown by recent research in neurology, by such bridge-builders as the Dutch investigators, Magnus and Brouwer, who in different domains of neurology have revealed the importance of the combination of morphological, experimental, and clinical methods in dealing with complex problems.

One could multiply examples almost without limit of the obtrusive part taken by theories of bodily structure, in particular of the heart and brain, in the building up of systems of philosophy and incidentally in effecting great reforms in knowledge. But it can also be shown that a lack of anatomical knowledge at certain epochs in the history of civilisation was responsible for hampering progress. In 1674 Malebranche (Recherche de la verité) expressed his belief [1] in the existence of vasomotor nerves (Nerfs qui environnant les artères pour fermer, par leur contraction, le passage au sang qui montre vers le cerveau, et l'ouvrir par leur relâchement à celui qui se répond dans toutes les autres parties du corps), but he lived two centuries before men had sufficient knowledge of bodily structure to appreciate all that was involved in this precocious intuition of genius.

Because anatomy had not prepared the way, for instance, the understanding of the injuries that produce aphasia had to wait for three centuries. In the year 1558 Nicholas Massa published an account of a case of traumatic aphasia, which disappeared after operation. The patient received a blow from a halberd that perforated the base of the skull and penetrated the meninges and brain, into which a fragment of bone was driven. He makes the comment, which in the mouth of a surgeon has a very modern and familiar ring about it, that the physicians had not noticed the depressed bone. Massa assumed that the loss of voice might be due to the pressure on the brain of the piece of bone he had detected. Hence in the presence of the physicians and other onlookers he proceeded to remove it. To their intense astonishment the patient at once recovered his speech.[2]

It was not until the beginning of the nineteenth century that, as the result of anatomical observations, Joseph Gall was able finally to demolish the old theory of animal spirits, and to prepare the way for the admission of the realisation of cerebral localisation. In a work published in 1818 Gall recorded a case of traumatic aphasia such as Massa had seen in 1558—an officer who received a sword thrust just above the left eye and lost "the memory for words." But it took more than another half century before physiologists and clinicians were willing to admit the reality of localisation, and then only when the genius of Hughlings Jackson and Broca and the experiments of Fritsch and Hitzig, Ferrier and others, had given the observations an anatomical setting by assigning to definite areas of the cortex the control of certain movements. The history of these 50 years is told in full by Dr. Henry Head in his great treatise on Aphasia and Other Disorders of Speech (1926).

With reference to the question of cerebral localisation it will be common knowledge that the histological investigations of Dr. Bevan Lewis from 1869 onwards established the fact of anatomical localisation. Yet Lewis's important work was brushed aside because the precise results obtained by him seemed to come into conflict with those obtained by experimental investigations. The difference in structure between the pre- and post-central convolutions of the brain was completely over-ridden by the fact that Sir David Ferrier and others obtained responses to electrical stimulation from both convolutions. It is important to remember that when Sir Charles Sherrington in 1900, using a more exact method of investigation, was able to prove that the post-central convolution was not excitable, the method of histological localisation was restored to favour, and the work which Dr. Bevan Lewis had begun more than 30 years previously was taken up with renewed vigour, and yielded some of the most significant additions to our knowledge of cerebral structure.

THE SYMPATHETIC NERVOUS SYSTEM.

The new chapter in the history of medicine created by the work of Gaskell, Langley, and Anderson on the sympathetic system was based essentially on anatomical investigations. Even the experimental part of their researches had as its chief objective the mapping out of the structural arrangements of this system. At the present time the question of the practical and clinical applications of this knowledge is the subject of lively controversy. There are grave differences of opinion in respect of almost every aspect of these problems. But in the long run the issue will be settled by the facts of anatomy. When we know more of the structure of the nerves passing to muscles and their connexions in the central nervous system, the decisive evidence for the solution of these difficult problems will have been attained. In respect of this matter the morphological outlook comes into direct conflict with the attitude taken up by many of those who rely solely on experimental evidence. It is generally admitted that muscles have two more or less distinct functions to perform, contraction and maintenance of posture. The brilliant investigations of Sir Charles Sherrington have demonstrated beyond question that posture is automatically regulated by means of proprioceptive reflex arcs. It is also admitted that in invertebrates there are separate and distinct muscles for performing these two functions, even though the movements of the animal are slow and clumsy.

To the morphologist, in whose outlook ideas of evolution loom more largely than they do to the mere experimentalist, it seems in the highest degree improbable that vertebrate animals, in which muscular activity attains a much higher degree of rapidity, skill, and complexity than it does in most invertebrates, there should reveal no corresponding differentiation of muscles and nerves for carrying out these two functions. For 50 years it has been known that there is a duality of innervation. We know that there are differences in muscular fibres—the thick and the fine—the relative proportions of which are responsible for the obtrusive differences in colour between red and white muscles. It seems, therefore, if one applies the morphological argument in the

[1] Quoted from Jules Soury, Système Nerveux Central, 1899, T. 1, p. 407.

[2] This case of Marcus Goss is reported in Nic. Massae Epistol. Medicinal., II., 90–91. Venetiis 1558, and a similar case in Fr. Arcaeus, *De recta curandorum vulnerum ratione*, 62–27, Antverpiae, 1574. My attention was called to these surprising records by the reference to them in Jules Soury, Système Nerveux Central, 1899, T. 1.

highest degree probable that the greater efficiency of the vertebrate muscle may be due to the fact that the two kinds of muscle-fibre, instead of being separate as they are in invertebrates, are intimately blended to form composite muscles.

We know that in the case of the viscera there are two functionally distinct groups of nerve-fibres, and it seems again highly improbable that the voluntary muscles, which have automatic functions to perform like those of the involuntary muscles and in addition the highly complex reactions associated with willed movements, should be less well equipped for these more complicated functions than the simpler muscles. It remains for anatomical studies to provide the explanation of the conflicting evidence derived from experiments and surgical operations.

SOME PRACTICAL APPLICATIONS.

In spite of the widespread neglect of morbid anatomy the development of cytology and the recognition of its fundamental importance in the investigation of cancer is bringing an increasing number of pathologists back to morphological studies.

An interesting application of such knowledge is now being made in clinical surgery, in which observations in the cytology of cancer (such as were made years ago by Sir G. Lenthal Cheatle) are being used by Dr. McCarty in the Mayo Clinic to determine the prognosis in cases of carcinoma.

Some observations that my colleague, Dr. H. H. Woollard, has been making on the neuro-muscular lesions of so-called beri-beri induced experimentally by depriving rats of certain vitamins, suggest that in the last resort the evidence afforded by the structural changes in muscles and nerves cannot be neglected in any estimate of the effects of food deficiency. This impression is even more emphatically confirmed by the observations on bone-growth by another of my colleagues, Dr. H. A. Harris. He has been able to demonstrate by anatomical studies that any diminution of the growth processes of the body (such as normally occur during the week after birth and in certain phases of puberty, as well as in grave illness, or even deprivation of a diabetic patient of his dose of insulin), will cause an opaque line to make its appearance in X ray photographs of bones. This has been mistaken for, and used as, a diagnostic sign of healed rickets, and the work of many observers has been vitiated by erroneous interpretations of the effects of vitamins, &c., on bone growth. Such results indicate that morphology provides criteria by which the influence of the various vitamins on growth and metabolism will in the future be tested—as for some years Prof. Herbert M. Evans in California has been doing—by their potency.

The knowledge of the arrangements of the tracts in the spinal cord that has been acquired within recent years seemed at first to have little more than an academic interest, or at most a use in diagnosing lesions beyond the scope of treatment. But in 1911 Dr. Spiller suggested that the knowledge could be put to the humanitarian purpose of relieving the terrible sufferings of patients with inoperable cancer. In the *Archives of Surgery* three months ago, Dr. M. M. Peet has described the truly wonderful results obtained by cutting that part of the antero-lateral column of the spinal cord which conveys impulses provocative of pain. Thus the unfortunate victims of incurable disease can get relief from their suffering without the resort to drugs, and at the same time retain other forms of sensibility and so be unconscious of the loss.

During the last ten years thorough investigation of the effects of nerve injuries in soldiers and the correlation of evidence so obtained with the facts of anatomy has enabled Prof. Stopford to extend and clarify our knowledge of the arrangement of the sensory nerves, and has given the surgeon new and exact methods for the diagnosis and prognosis of nerve lesions. Only four years ago the pancreas used to be cited as an example of an organ which when diseased could give rise to such profound changes in the whole organism as we know in diabetes without revealing any structural indications of disease. But we now know that this is no longer the case. The morphological changes in the islands are clear enough once one knows where and what to look for in the way of morbid change.

The identification of the anatomical localisation of the lesions of encephalitis lethargica and morphological studies to determine the sites of injuries to the midbrain and hypothalamus that in experiments and clinical cases give rise to definite reactions of body and mind will eventually give us a new insight into the physical factors concerned with personality, but also the neural processes concerned with the manifestations of the common symptoms, such as raising of the body temperature, nausea, &c., in grave constitutional diseases with which every medical practitioner is daily concerned.

These instances chosen at random are enough to indicate that in the near future anatomy promises to become the stepping-stone to a new revelation of knowledge which will illuminate the whole field of human endeavour.

In this address I have endeavoured to suggest the vastness of the opportunities that now present themselves in anatomy and how vitally they affect the progress of surgery, not merely the mere craft of operating, but also the wider problems of diagnosis, prognosis, prevention, and treatment. This College has the power actively to promote progress in these lines, which I hope you will permit one who is beyond the pale of your membership to mention. By means of the primary examination for its Fellowship it can insist that the rising generation of British surgeons is inspired with the true spirit of understanding of the human body and is alert and open-eyed to appreciate the great vision that is about to be revealed. Instead of helping the persistence of mediæval conceptions of anatomy, it can encourage a kind of anatomy that is in organic touch with really vital problems.

The College has in its great Museum the most valuable instrument for promoting the study of anatomy on right lines. The growth of the collection started by John Hunter is one of the great scientific achievements of the last century, and under the direction of Sir Arthur Keith the opportunities for the comparative study of anatomy have been brought to a higher pitch of efficiency than ever. The College has it in its power to induce the candidates for its Fellowship to avail themselves of this wonderful instrument that is now too much neglected, and in doing so it will enhance the importance of the College itself and raise the standard of the science and practice of surgery.

LONDON CLINIC OF PSYCHO-ANALYSIS.—This clinic has recently been opened at 36, Gloucester-place, W. 1, for out-patient treatment by psycho-analysis. The clinic is intended to bring a method of treatment that is lengthy, and therefore expensive, within the reach of those who cannot afford the usual, or indeed any, fees. It will also afford an opportunity for the training, under supervision, of medical students and practitioners who desire to specialise in this branch of work. The staff consists of the following honorary physicians: Ernest Jones (hon. director), Douglas Bryan, E. M. Cole, M. D. Eder, E. Glover, M. B. Herford, W. Inman, Sylvia M. Payne, R. M. Riggall, W. H. B. Stoddart, and John Rickman (hon. secretary).

NORTH AND EAST RIDING MEDICAL BENEVOLENT SOCIETY.—The Medical Benevolent Society for the North and East Ridings of Yorkshire and the City of York recently held its eighteenth annual meeting at York. The financial statement showed that there was a satisfactory balance in hand, and the trustees were directed to make a further investment from the funds of the society. The objects of the society are to give assistance to its members or their families where it may be needed owing to death, illness, or other disability. It was felt that the work of the society was not sufficiently known amongst the profession, and steps are being taken to bring its claims before all practitioners in he district,

STUDIES IN BLOOD-SUGAR.

BY ELSIE PORTER, M.B., CH.B. EDIN.,
MEDICAL REGISTRAR, ANCOATS HOSPITAL, MANCHESTER;
AND
GEORGE J. LANGLEY, M.D., M.R.C.P. LOND.,
PHYSICIAN, ANCOATS HOSPITAL; HON. ASST. LECTURER IN HUMAN PHYSIOLOGY, UNIVERSITY OF MANCHESTER.

THE introduction by MacLean and others of simple methods by which the amount of sugar in a small quantity of blood could be accurately and quickly estimated has completely altered medical work on diabetes and glycosuria.

The use of insulin in the treatment of diabetes has necessitated the application of blood-sugar estimations in the treatment of almost every case. This is necessary first, for the differentiation of cases of renal glycosuria, to determine the renal threshold for sugar, and second, in the course of insulin treatment to control the dose, more particularly when sugar has disappeared from the urine. Increased knowledge of any disease usually brings with it the possibility of earlier diagnosis, and this is particularly true in diabetes, where the term "potential diabetic" is already in current use. The method by which such a condition is found is to estimate the patient's capacity to deal with a known dose of glucose taken by mouth after 12 hours' starvation, the blood-sugar being estimated before and at frequent intervals afterwards.

The test usually adopted is as follows. The patient takes no food during the night. The blood-sugar is estimated the next morning and 50 g. glucose are given in 100 c.cm. water. Thereafter the blood-sugar is estimated every half hour until six specimens have been examined. The urine before and after the test is also examined for sugar. The results may then be expressed on a chart with percentage blood-sugar as ordinate and time intervals as abscissa.

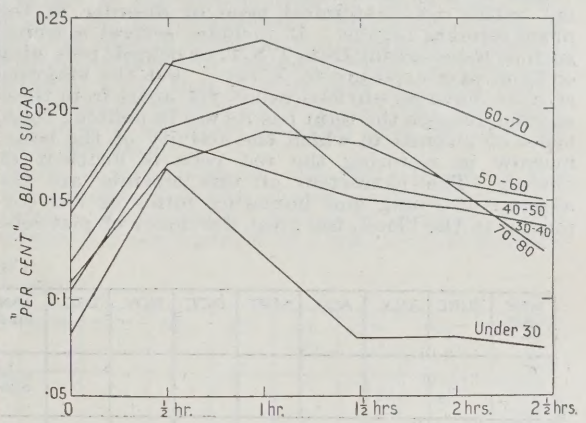
It is generally recognised now that the physiological response to 50 g. glucose during the early years of life—i.e., up to 30 years of age—will show a fasting blood-sugar level of 0·08 per cent., rising in half an hour to 0·17, but returning to the fasting level in one and a half hours, and that no sugar will appear in the urine. It is believed that the return to normal level is not due to cessation of absorption, but to the activity of the sugar storage mechanism, which appears to come into action at a concentration of 0·17 per cent. blood-sugar, which is also the renal threshold value for sugar. Authorities agree that some delay in this mechanism is usual as age advances, and it was with a view to obtaining some estimate of the amount of this physiological delay that this work was first undertaken at the suggestion of Prof. H. S. Raper.

Fifty normal individuals have been examined on the following plan: Ten cases in each decade, starting at 30 to 40, of mixed men and women were taken. Each case was starved overnight and the starving blood-sugar level estimated; 50 g. glucose in 100 c.cm. water were then given, and the blood-sugar estimated at the end of each half hour for two and a half hours, the urine being examined at the expiration of that time (see table). All the sugar estimations have been made by MacLean's method.

Age.	1	2	3	4	5	6
	Before.	½ hr.	1 hr.	1½ hrs.	2 hrs.	2½ hrs.
Under 30	0·080	0·170	0·125	0·080	0·080	0·080
30–40	0·105	0·184	0·174	0·153	0·150	0·140
40–50	0·120	0·192	0·207	0·165	0·155	0·152
50–60	0·146	0·225	0·218	0·195	0·166	0·155
60–70	0·145	0·225	0·238	0·245	0·205	0·185
70–80	0·115	0·175	0·190	0·185	0·165	0·130

Results.

The readings were averaged for each time-period and the results charted. The curves obtained are shown in the accompanying diagram which appears to demonstrate the following points: (1) That the starving blood-sugar level tends to rise from the normal 0·08 per cent. of youth to nearly 0·15 per cent. at 70 years of age. (2) That the actual increment of sugar-content of the blood, however, remains the same and is always less than 0·1 per cent. (3) That at the ages considered the highest point of sugar concentration is liable to be reached at the end of one hour, rather than at the end of half an hour as is usual in youth. (4) That there is an increasing delay in return to the starving level, which fails to occur in the two-and-a-half hour period of observation. (5) That in the decade 30 to 40 years of age urinary sugar in response to 50 g. glucose is not found, but in the decades above this glycosuria in response to this amount of sugar occurs in about 30 per cent. of tests, being rather higher in the decade 60 to 70 years of age, when it is nearly 40 per cent. (6) In the decade 70 to 80 the type of curve obtained differs greatly in that it does not rise so high, but takes considerably longer to return to starving level. No explanation of this is offered, but the patients were senile.



Conclusions.

From this it would appear that glucose tolerance curves should be interpreted not only from the point of view of the blood-sugar rise and the period occupied in returning to starvation level, but also with due regard to the age of the patient. The increased lag in the curve, apart from age considerations, might easily lead to an opinion of potential diabetes when in reality it is believed that the delay is the physiological result of age. This is particularly liable to be misleading in patients complaining of such troubles as pruritus and sciatica, which may or may not be diabetic in origin.

The smallness of the numbers examined must deprive these results of some of their value, but it is hoped that other workers may have similar figures to add and so increase the evidence which appears to have so important a clinical bearing. The possibility of administering glucose per rectum to cases of diabetic coma is so obvious when unconsciousness prevents voluntary swallowing that some evidence of adequate absorption becomes imperative. Blood-sugar curves taken hourly for four hours after the administration of 50 g. glucose with bicarbonate of soda in a 10-oz. enema have been made in ten cases; in two cases the observations were continued for six hours. In no case was any rise in the blood-sugar demonstrated.

It is therefore believed that glucose cannot be administered by this route with any reasonable hope of adequate absorption, and there is no evidence that glucose added to rectal salines is absorbed in sufficient quantity to raise the sugar-content of the blood at all.

THE ACTION OF ADRENALIN IN APLASTIC ANÆMIA.

By ALEXANDER GEORGE GIBSON, M.D. Oxf., F.R.C.P. Lond.,
PHYSICIAN TO THE RADCLIFFE INFIRMARY, OXFORD.

THE term aplastic anæmia is not that of a disease but rather an anatomical type of disorder of the blood-forming organs. It includes several anæmias such as those arising from T.N.T. or benzole poisoning or from over-exposure to X rays; but the majority of cases have no obvious cause, yet apart from these specific diseases the term has its use in defining those types of anæmia in which the activity of the bone-marrow in restoring the red cells is deficient or absent. The characters of this anæmia are the absence of young and immature forms of red corpuscles in the blood, the great deficiency of platelets, a leucopenia due to deficient polymorphonuclears, and a pale gelatinous condition of the red marrow seen post mortem. The following case belongs to this type.

J. S., a girl of 11, began, in the spring of 1923, to look paler than normal and to suffer from bruises in various parts of the body which appeared without obvious cause. Early in May of that year she was taken to see Dr. George F. Still who, after seeing a careful report on the blood by Dr. Carnegie Dickson, gave a very serious prognosis, and she was sent home to be under the care of Dr. King Edwards, of Watlington, to be treated by arsenic subcutaneously and by the mouth, and by transfusion if her condition failed to improve.

The condition of the blood at this time was as follows (Dr. Dickson): R.B.C., 1,990,000 per c.mm.; W.B.C., 4850 per c.mm.; Hb. (Gowers), 42 per cent.; colour-index, 1·06. Differential count (per cent.): Polymorphs, 12·3 (total, 596·5); lymphocytes, 86·6 (total, 4200); large mononuclears, 0·0; eosinophils, 1·0. There was considerable anisocytosis, with excess of large pale forms of red cell. Poikilocytosis was also present. There were no nucleated red cells or punctate basophilia and the platelets were very scanty. No malarial parasites were seen.

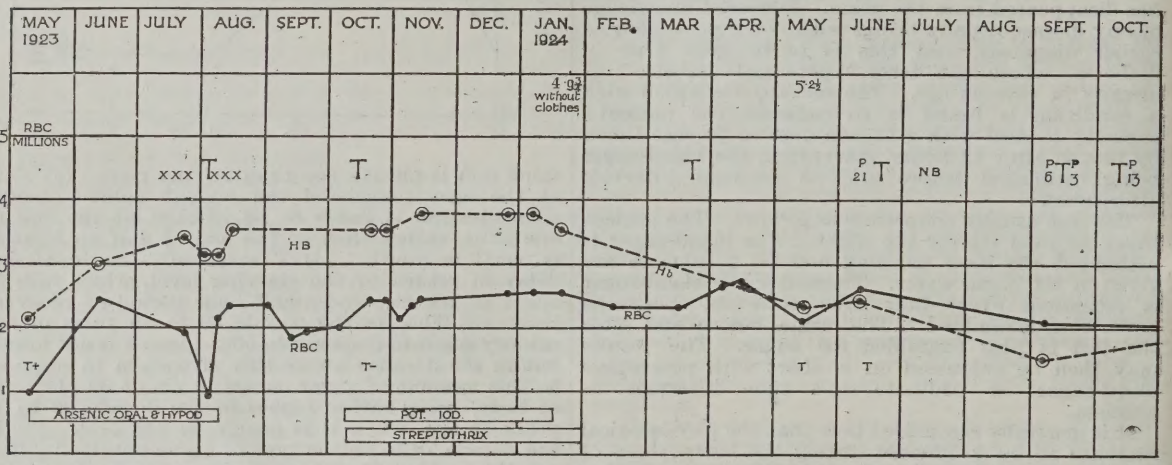
Soon after this I was asked to see her with a view to a transfusion if the necessity arose. She was at that time a pale, delicate-looking child with rather a dark skin, especially of the abdomen; there were several bruises about the body, and a slightly enlarged liver and spleen. She had a small daily rise of temperature. There was nothing of note in the family history; both the father and mother were healthy. The patient had been born in India, where she had lived till the age of 7, but except for an attack of fever, thought to be malarial, there had been no serious illness.

Investigations were undertaken to search for some ætiological factor. An extended search revealed no malarial parasites in the blood, the blood culture was negative, two guinea-pigs injected with fresh blood suffered no inconvenience and showed no trypanosomiasis or spirochætosis. There were no parasites in the fæces and the urine was normal. It was then determined to try certain lines of treatment and ascertain by her general condition and that of the blood whether any improvement occurred. Arsenic for two months gave no general improvement, though the red cell count rose slightly. Six exposures to X rays were then given over the spleen without effect, if anything with slight deterioration in the blood condition. During this period the first transfusion of half a pint of her mother's blood was given by the citrate method. Two months after, in October, 1923, another transfusion became necessary owing to deterioration in her general condition. Her blood condition was also probably much below that shown in the chart, which does not show the state before but after each transfusion. Previous to this for three weeks a vaccine of a sarcina which had appeared in one of the blood culture-tubes was used on the chance of its being a remotely possible ætiological factor. After that potassium iodide and a vaccine of a stock culture of a *Streptothrix actinomyces* was used, with some slight improvement. The rise of temperature ceased during the early part of this treatment. After three and a half months there was clear evidence that the general trend of the disease was downward. She was given without benefit four intravenous injections of antimony tartrate on the possibility of kala-azar being a factor, and she was given a short course, also without effect, of quinine.

A third transfusion was given in March, 1924. In May, 1924, she was slightly heavier than in the January previous; in this month the temperature again showed a slight daily rise. In the June following, when at the age of 12, her first menstrual period began and lasted 21 days. During this the fourth transfusion was given. From this time her progress was steadily downwards. There was a bad attack of nose-bleeding in July, 1924. In September, 1924, she had two menstrual periods of six and three days respectively, between which the fifth transfusion was given. Another transfusion was given in October, 1924, and there followed a menstrual period lasting 13 days. In November there were two menstrual periods of 13 and 10 days respectively. In December, 1924, the patient was extremely ill, blanched, with many bruises, occasional nose-bleedings; a menstrual period during that month lasted 24 days. She was given her seventh transfusion at the very end of the month and I left the patient not expecting to see her alive again. The transfusion produced little effect. Pituitrin on the second day was given in an attempt to control the uterine hæmorrhage. The condition of the patient was desperate, and as a pure experiment suggested by her pigmented skin she was given daily subcutaneous injections of adrenalin (Parke, Davis and Co., 1/1000 solution), beginning with 2 minims and increasing gradually to 5 minims.

From the time these injections began improvement set in; the menstrual periods after one of seven days in February, 1925, have become regular five-day periods every

CHART 1.



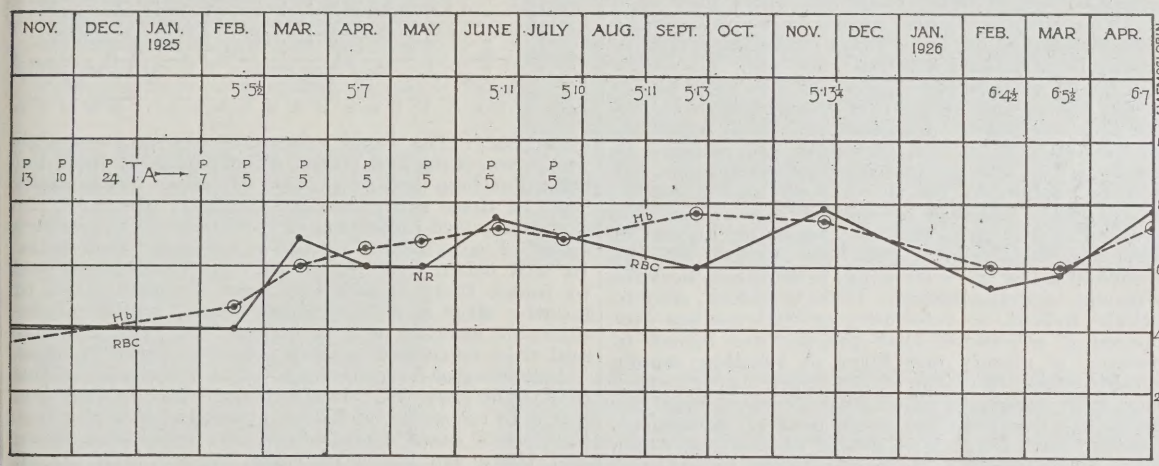
The continuous line represents hæmoglobin. The second to the twelfth of these estimations (June, 1923, to January, 1924) were made by the Talquist scale and are probably too high. The rest are made by Haldane's hæmoglobinometer.

The interrupted line represents red blood cells. T = transfusion; T = presence of temperature; P = menstruation, number of days; A = beginning of treatment by adrenalin; X = X ray treatment. The weight in stones and pounds is marked below the second horizontal line. N.R. = nucleated red cells seen in blood.

month. Her weight, which despite the severity of the illness had increased slightly, began to show a steady increasing rise, and in December, 1925, it had increased 8 lb. In the year beginning February, 1925, and ending February, 1926, she had put on a stone all but a pound in weight. General improvement in strength occurred with this and the patient gradually resumed normal habits with due care during the monthly losses. At the time of writing, July, 1926, she is a slightly made but otherwise normal girl of 14, a little paler than the average but able to run about and play with her fellows. The blood condition, however, has never returned to normal. The last count taken on July 15th, 1926, is as follows: R.B.C., 3,490,000; Hb., 72 per cent.; colour-index, 0·95; W.B.C., 4680. Differential count (per cent.): Polymorphs, 32·5 (total, 1521); small lymphocytes, 45·5 (total, 2120); endothelials, 16·5; eosinophils, 0·5; neutrophil myelocytes, 4·0; eosinophil myelocytes, 0·5; large lymphocytes, 0·5.[1]

The chart shows that since the adrenalin was used the red cells have varied between 3 and 4 million and the hæmoglobin between 60 and 80 per cent. The appearance of the red cells has altered; the size is more regular, polychromasia is present, and rarely an occasional nucleated red cell has been found, not seen previously.

CHART 1. (*continued*).



There has been a slight but significant change in the white cell count, as follows. The counts are the average of all records, 14 before and 11 after the administration was begun.

	Total leucocytes.	Polymorphs.	Lymphocytes.
Before adrenalin ..	2558	534	1439
After ,, ..	2894	971	1311
Normal average ..	5000	3250	1000

In all counts, therefore, there is evidence that the adrenalin has effected a change in the direction of, though not up to, the normal.

Remarks.

The patient whose story is given above has made an apparent recovery from a severe grade of aplastic anæmia of unknown ætiology, a type of anæmia almost invariably fatal. The beginning of the recovery coincides with the giving of daily injections of adrenalin, which has been continued, omitting one day in each week. It will be noticed that the blood count still shows some of the changes present at first—viz., diminution of leucocytes and of the total polymorphs—and both the red cells and the hæmoglobin are below normal; on this account it has not been thought desirable to omit the adrenalin for a period to ascertain whether the patient could maintain the improvement. There has been no deleterious effect of the adrenalin; the blood pressure has not been found above 120, there has been no hypertrophy of the heart, and no thickening of arteries. It is possible to argue that the recovery of the patient is due to natural causes such as occasionally happens, as in the case reported by J. Porter Parkinson.[2] In this case, however, the recovery was complete even to the blood count recovering its normal state. In the present case the recovery was evident within a week of giving adrenalin at a time when the patient's condition was extremely critical.

It is probable that the adrenalin acted as a direct stimulant to the bone-marrow of which some still remained to be stimulated. This action has been used with effect in rickets and osteomalacia.[3] [4] Certain experiments made by Berchtold [5] bear on this case. Berchtold found that in large dogs adrenalin causes many more young forms of both red and white cells to be seen in the blood emerging from the nutrient vein of the tibia.

There is some evidence also that absence of the normal secretion of the adrenal gland may produce anæmia. Occasionally Addison's disease of the suprarenal is accompanied by a mild grade of anæmia. Hutchison [6] records that in the suprarenal sarcoma of children there is a profound secondary anæmia.

I have not had an opportunity of trying adrenalin in another clear case of aplastic anæmia; in those cases of Addison's anæmia (pernicious anæmia) in which I have tried it there has been no beneficial effect.

[1] A further blood count on Sept. 17th, 1926, gave R.B.C., 4,410,000; Hb., 81 per cent.; W.B.C., spoiled. Differential count; polymorphs, 41 per cent.; small lymphocytes, 54 per cent.; endothelial cells, 5 per cent.

LIVERPOOL HOSPITAL AMALGAMATION.—The amalgamation of the Liverpool and Samaritan Hospitals for Women has now been carried a step further by the laying of the foundation-stone of the new joint building, which is to provide accommodation for 120 beds at a total estimated cost of £120,000. Of this sum £61,000 has already been raised. Along with the recently opened Maternity Hospital this new institution will make very complete provision for the care in Liverpool of diseases peculiar to women.

COLOURING MATTER IN MILK.—The Lancashire county analyst, in his annual report, states that of 4539 samples analysed during the year 1925, under the provisions of the Food and Drugs Acts, 487 were found to be unsatisfactory, four-fifths of them being milk samples. He points out that anatto which is largely used in colouring cheese, is quite harmless in itself, but the effect of its addition to milk is to impart a fictitious appearance of richness, and where the milk is really poor in fat, to conceal inferior quality. The use of any colouring matter in milk is now contrary to law, although many vendors appear to be unaware of the fact.

EPIDEMIC ENCEPHALITIS IN DOGS.

BY LESLIE P. PUGH, B.Sc., F.R.C.V.S.,
HON. SEC., SECTION OF COMPARATIVE MEDICINE, ROYAL SOCIETY OF MEDICINE.

THE epidemic with which this note deals, including more than 50 fatal cases, was one of what veterinary medicine has long known as the nervous form of distemper. Its chief interest lies in the fact that the occurrence of a number of quite definite "lethargic" cases leads to a closer comparison than has hitherto been made between the human and canine disorders. From this comparison it appears that both in symptomatology and in the character of the cerebral lesions the two diseases are almost identical. This similarity is so close that we are forced to conclude either that the two are the same disease but in different animals, or, alternatively, that the lethargic and encephalitic symptoms are not in themselves entitled to rank as a "disease"—i.e., a morbid process associated with a single virus, but are merely a particular form of reaction to which more than one virus may give rise. The former thesis seems to be difficult to support with any but superficial evidence, and may probably be dismissed without more ado. The latter has much to recommend it, especially in view of the fact that the canine form is everywhere acknowledged to be but one aspect of distemper. It is fortunate that the other forms of distemper are striking in character—e.g., the bronchi-septicus pneumonia, the symptoms referable to the throat and digestive tract. The occurrence of epidemics in which the prevailing type has included one or more of these, but which have yet been varied by the presence of a few cases showing, in addition, nervous symptoms, is well attested. It is, therefore, easy to conclude, indeed, no veterinary practitioner has ever supposed it otherwise, that the nervous aspect of distemper is merely one form of reaction among several to which the virus of distemper may give rise.

But with regard to the human form of epidemic encephalitis there is no such general agreement. It is true that there is a school of thought which regards it as bearing some such relation to influenza as does the canine form to the primary catarrhal type of distemper. But these views have not hitherto been supported by any such striking analogy as it is here sought to adduce, and have not gained wide acceptance. It is, however, noteworthy that very few have cared to deny in toto the validity of the evidence brought forward, and the arguments of those who have opposed this connexion are such as to leave the question still sub judice.

It is such considerations as the above which have suggested that the particular epidemic dealt with herein may have a medical and even an epidemiological rather than a purely veterinary interest. The line of argument which it seems to suggest, and which more expert pens will perhaps see fit to debate, is briefly as follows:—

(*a*) An epidemic of the nervous type of distemper has been observed in which persistent sleepiness, ocular palsies, hiccough, and other clonic spasms, together with changes in disposition, &c., have been evident.

(*b*) The lethargic cases have shown typical "cuff" lesions in the brain, minute hæmorrhages, major incidence on the basal ganglia, &c.

(*c*) Both symptoms and lesions are so exactly similar to those of the human disorder known as epidemic encephalitis that the identity of the two diseases, distemper and encephalitis, might well be considered.

(*d*) For various reasons such identity is improbable, and we are thus led to the conclusion that the encephalitis syndrome is not a disease per se—i.e., ætiologically regarded—but merely a type of reaction which may be evoked by more than one virus, for example, by those of distemper and of human encephalitis.

(*e*) In the case of distemper the same virus may in different epidemics give rise to other reactions—e.g., the pneumonic, the gastro-intestinal and cutaneous, &c.

(*f*) In the case of encephalitis lethargica of human beings no such forms have been described, except by those who associate it with influenza, which, like distemper, has a "standard" relatively mild catarrhal type, and at least one other well-marked type, the pneumonic.

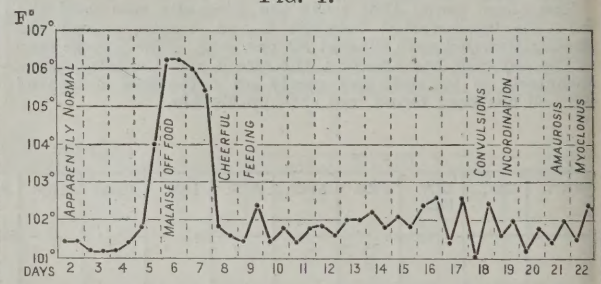
(*g*) Such argument as may properly be drawn from analogy is therefore in favour of those who regard epidemic encephalitis as a phase of influenza.

Details of an Epidemic of Distemper of Nervous Type.

The epidemic occurred at Sevenoaks, March to July, 1926.

Primary Stage.—This lasts from a few days up to three weeks, averaging ten days, before the onset of localised nerve changes. The usual symptoms were weakness, shivering, depression (Fig. 1), and high fever for two or three days, then a lower and intermittent temperature, conjunctivitis, salivation (mucinous),

FIG. 1.



naso-pharyngitis, rapid pulse, muscular and neuralgic pains, vomiting and thirst, constipation at first, but later diarrhœa in a proportion of cases. Occasionally none of these symptoms was actually observed, the first recognised indication of trouble being the sudden onset of convulsions or other nervous phenomena. In still other cases these nervous changes seemed to make their appearance only several weeks or months after a mild primary stage, whilst a considerable number of dogs showed the primary stage and then recovered without obvious nerve changes.

Secondary or Nervous Stage.—The description of this stage is no easy task. It is true that the clinician soon learns to recognise particular types, but it is also true that some cases change from one type to another, and there are many aberrant types which almost defy classification. Nevertheless, some form of classification has been found inevitable, and it has seemed better to base this rather on the mode of progress in each case than on particular symptoms.

(*a*) *Hæmorrhagic Type.*—A most acute fulminating type.

(*b*) *Transient Type.*—The characteristic of this type is the rapid and complete disappearance of symptoms within a few days. Thus a dog might one day show neuritic pains in one limb together with paresis, the next day another limb might be affected, and after that no symptoms of any sort persisted. In another case there might be for two or three days very definite myoclonus, and thereafter complete recovery. This class also includes certain cases with curious psychic symptoms, of which the tendency to run away like a rabid dog until overtaken by a convulsive attack was one of the most surprising. The psychic symptoms might equally be of a more negative type, the dog hiding under chairs or tables and shunning mankind, &c.

(*c*) *Relapsing Type.*—In general this type was either neuritic or myoclonic (Fig. 5) or both, the characteristic feature being the tendency to periodic recovery and relapse. Not infrequently it eventuated in a paralytic phase.

(*d*) *Paralytic Type.*—In this paralysis, commonly of the hind limbs, was an early symptom. This paralysis was flaccid, and considerable wasting was present.

(*e*) *Progressive Type.*—Here there are two subtypes, widely different in their symptoms, but alike in that they progressed fairly rapidly to a fatal termination. The first subtype is the

Lethargic type. The symptoms were usually lethargic at an early stage, as some of the case-histories show, but in Case 16 the disease first manifested itself by paralysis of the hind limbs, then affected the forelegs, and finally gave rise to typical lethargy and death. Case 10, a black mongrel terrier aged 2 years, was presented for examination. Temperature 102·5° F., rapid pulse, and injected conjunctival blood-vessels. A tentative diagnosis of distemper made. Two days later a slight pharyngeal cough developed. Nine days after the onset of malaise the dog appeared very drowsy. Although he appeared to spend most of his time standing up, yet he continually "nodded off" to sleep in

this position. At other times he would be found asleep leaning against the wall. If spoken to he would awaken, but doze off again within a few minutes. If forced to move he did so with slight incoördination of movement. Nystagmus present. He died in deep coma four days later. Histological examination of the brain in this case revealed lesions identical with those found in epidemic encephalitis. (See Figs. 2, 3, and 4.)

FIG. 2.

Perivascular cuff in basal ganglia region in case showing profound lethargy and coma. (× 200.)

FIG. 4.

Lethargic case. (× 100.)

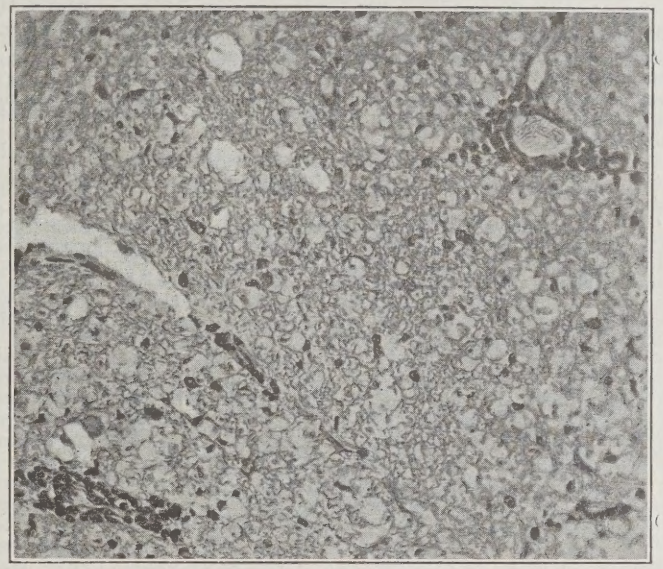
(2) The cerebellar type.—The cases in this group presented a curious form of head retraction. They had the appearance of continual effort to draw the back of the head more and more down on the spine. They commonly fell over backwards. They showed more often than other groups acute tenderness behind the ears, and such eye troubles as failure of accommodation, nystagmus, and definite strabismus were often seen. These dogs behaved as if blind or partially so. They were definitely ataxic.

Sequelæ.—Most acute cases, if not fatal, were destroyed owing to the change in temperament and physical changes encountered. After acute and progressive symptoms had long subsided some of the following might be observed :—

(1) Choreiform movements. Sometimes permanent, at other times intermittent, affecting any single muscle or group of muscles in any part of the body. These movements become more exaggerated when the animal is fatigued or excited.

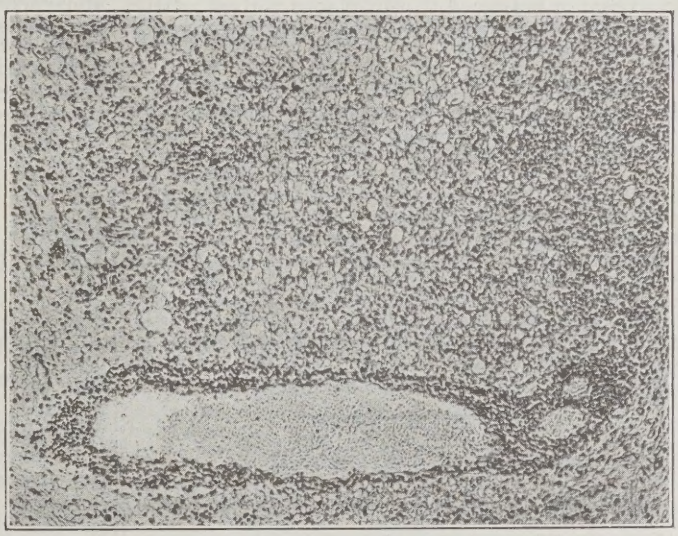
(*b*) Paralyses, especially of hind limbs. This type commonly follows the peripheral neuritis cases, and although there is a definite tendency to recover slowly over a period of many months, residual paralyses did occur in some cases.

FIG. 3.



Case 24.—Cranial lesions. Lethargic. (× 200.)

FIG. 5.



Cellular infiltration in basal ganglia region of case showing myoclonus. (× 100.)

Complications.—(1) Herpes affecting the lips, conjunctivæ and eyes. (2) Gastritis or gastric congestion by no means uncommon. In some cases actual ulceration of the gastric and duodenal mucosa has been observed.

Mortality in those showing local nervous changes probably not less than 50 per cent.

Prognosis.—Very difficult. Some of the most severe cases, if persevered with, would apparently recover completely, whilst others showing the mildest or most transient of prodromal symptoms would terminate fatally. The progress of the disease itself is so variable from day to day that one dare not give any great hope, and even after apparent recovery, the animals' owners have to be warned against the

possibility of nervous phenomena arising should the animal become over-fatigued or unduly upset, overfed, &c., during the long convalescent period.

Macroscopic Changes.—The naked-eye changes in the nervous system are slight. The "milkiness of arachnoid," described by Da Fano and Ingleby, would be a very apt description of what one observes when the cerebellum is exposed in some of the more acute forms. Minute hæmorrhagic foci can frequently be detected in the region of the basal ganglion after a median incision, giving a "mottled" appearance. Such hæmorrhages are seen but less frequently in the cortex but were not noted in the meninges, the chief focus of infection would seem to be in the grey matter, although occasionally lesions could be found in the white matter.

Microscopical Changes.—Hall, in describing the histological changes met with in epidemic encephalitis, states :—

"The virus shows 'its most arresting change' (Miller) in the reaction of the blood-vessels. These are both vascular and perivascular, and occur chiefly 'round veins of a certain diameter, above all, round precapillary veins' (Marinesco). The vein is 'surrounded by a sheath of varying thickness, consisting of deeply stained nuclei of a round appearance' (Marinesco). This perivascular infiltration or perivascular 'cuff' is a regular phenomenon. The infiltrate occupies chiefly the Virchow-Robin space, and is composed of mononuclear cells. . . . Whilst the fibres of the vessel wall are dissected by the cellular infiltrate and the perivascular lymph space distended by it, the intima in most cases remains intact. . . . Besides the perivascular cuffs or adventitial infiltration, the affected areas are characterised by the presence of small scattered masses, microscopical in size, each composed of more or less loosely packed collections of small round cells." (See also THE LANCET, Jan. 2nd, 1926, p. 29.)

This description is equally true of the encephalitic form of distemper. It may, however, be noted that the "cuff" changes were generally very well marked both in the cranial and cord structures, and that there was no sign of polynuclear cells placed perivascularly. It should also be noted that apparently pure cranial cases show cord lesions.

Bacteriology of Distemper and Influenza.

In conclusion, one may perhaps be permitted to comment on the bacteriology of the pneumonic forms of distemper and influenza. That occurring in distemper is usually due to the *B. bronchi-septicus*, but the view that distemper is due to a filter-passing virus is now so general (Distemper Commission findings) that the *B. bronchi-septicus* is regarded as a secondary invader. It seems (F. W. Andrewes, see Official Report on 1918 Epidemic) that Pfeiffer's bacillus has a somewhat similar position in relation to the causation of influenzal pneumonia, and it may be that a virus will presently be demonstrated which will clear the situation. The parallel between the two diseases would appear to be too close to be disregarded.

HALOGEN ERUPTIONS.

BY ARTHUR J. HALL, M.D., F.R.C.P. LOND.,
PROFESSOR OF MEDICINE, UNIVERSITY OF SHEFFIELD, AND SENIOR PHYSICIAN, SHEFFIELD ROYAL HOSPITAL.

IN THE LANCET of Oct. 16th (p. 803) Dr. H. C. Semon records an unusual case of iodide eruption, following a comparatively small dose of the drug, as a matter of fact, 10 grains altogether. His interesting account of the case, and the illustration which accompanies it, reminds me of a similar one which I saw nearly 30 years ago. As cases of this severity are so rare and so disturbing when they occur, I venture to quote a short account of it, which was published in 1906 [1] :—

In 1898 I was asked by a medical man to see a case with him of very severe anthracoid acne in a young woman, the subject of subacute nephritis. She had been progressing satisfactorily until May 8th, when she was given a 3-grain dose of iodide of potassium. This was repeated three times during the next 24 hours, so that she took altogether 12 grains of the drug. On May 10th a rash appeared on the face, as a papule on the right lower eyelid. This gradually enlarged and more similar papules appeared on other parts of the face. I saw her first on May 13th, when her condition was as follows. Under each eye there is a semicircular, papillomatous, tuberose swelling completely filling the lower lid pocket. These are extremely tender and painful, very vascular, and covered with a kind of crust. On removing a portion of crust there is profuse bleeding of what appear to be elongated papillæ. Similar tense rounded tuberous swellings are situated here and there on the nose and cheeks. On the right side of the tongue at its edge there is a pointed oval projection about the size of half an almond. It is extremely painful and causes the tongue to be protruded to the left. It is smooth and tense, and looks like a small tongue growing out of the large one. This occurrence of a lesion on the tongue, similar to those on the face, has, so far as I am aware, not been previously observed. In one case, recorded by Morrow, the tongue and fauces were extremely congested. On May 18th the patient's condition was very distressing, the repeated severe bleeding, whenever the spots were dressed, and the pain and discomfort of them were very great. On May 28th pericarditis developed and she died a few days later.

It will be noticed that in this case there was a definite involvement of the tongue, which added considerably to the pain and discomfort caused by the eruption. At the time I saw this case it seemed probable that the presence of seriously defective kidneys played some part in the occurrence of this reaction so out of proportion to the small amount of the drug taken—namely, 12 grains in all. For some time after this I felt some hesitation in giving iodide of potassium in cases suffering from nephritis. However, since then I have often seen it given in such cases by others, and have prescribed it myself without any such untoward results, and it seems clear that this peculiar effect of the drug is really an individual idiosyncrasy, whatever that may imply, and is independent of the powers of elimination. I am glad to see that this view is confirmed by Dr. Semon's case, in which it is noted that the urine was normal.

These cases are so rare that any investigation into the nature of the "idiosyncrasy" is impossible. Nor has any explanation been offered as to why the worst of the trouble is usually in a somewhat circumscribed area around the eyes. In the paper written in 1906 and referred to above, I called attention, on clinical grounds, to the possibility of light rays playing a part in developing and localising these rashes in exposed parts. At that time very little attention had been given to the whole question of the action of light on the skin. It is interesting to note that during the last few years with the development of our knowledge of X rays, violet rays, &c., increasing attention is being given to this important question, and the effects which light in various forms can produce, both locally and generally, when acting upon the skin are now definitely recognised.

In conclusion, there are two facts which are worth remembering in connexion with eruptions due to the halogens. They may follow very small doses of the drug administered over a very short period and they continue to increase in extent for a considerable time—in the case of bromides sometimes for several weeks—after the drug has been entirely omitted. For these reasons it is often difficult to persuade the doctor who has administered the drug on the one hand, or the patient and his friends on the other, that it is a case of cause and effect.

PRESENTATION TO DR. G. E. SCHOLEFIELD.—Dr. George Edward Scholefield, M.B.E., Ormskirk, medical officer of the West Lancashire Rural Council, was on Oct. 22nd presented with a silver rose bowl from the members of the council on the occasion of his retirement, after 28 years' service with the council. He was also presented with a silver epergne from the officials and staff of the Aughton Isolation Hospital, of which he had been medical officer since its opening 25 years ago.

Medical Societies.

ROYAL SOCIETY OF MEDICINE.

SECTION OF DISEASES OF CHILDREN.

THE provincial meeting of this Section, postponed from June, was held at the Children's Hospital, Birmingham, on Oct. 30th, Mr. PHILIP TURNER, the President, being in the chair.

EXHIBITION OF CASES.

Dr. L. G. PARSONS showed a series of cases with radiograms illustrating

Cœliac and Renal Rickets.

The cases of cœliac rickets showed the development of this condition and its cure by limitation of fat in the dietary, the application of ultra-violet light, and the giving of irradiated cholesterol. He pointed out that in a young child the subject of cœliac disease the bones were fragile and atrophic in appearance, the cortex thin, and there was a general osteoporosis, but the epiphyseal line was quite sharp. Later on, about the age of 7 to 10 years, when growth was more rapid and the child more active, in addition to this general atrophic appearance there were obvious rachitic changes at the epiphyseal line and fractures were liable to occur. In the severest type of the disease there was a marked osteoporosis and extreme degree of rickets at the metaphysis with many fractures. The cases also showed that healing of the severest type would occur with the treatment outlined.

The cases of renal rickets were divided into three groups :—

(*a*) The *atrophic* group, in which the picture resembled that seen in cœliac disease—e.g., an osteoporotic and atrophic bone, with a thin cortex, and rickets at the epiphyseal line. This type, if the child survived to the age of 16 or 17 years, was frequently found to heal, and the healing was probably due to the fact that the child had reached the end of the growing period.

(*b*) The *florid* type, which showed a picture similar to that seen in ordinary rickets, and which in the case exhibited showed complete healing.

(*c*) The *woolly* type. In this type the metaphysis showed a curiously woolly, eroded, or stippled appearance, quite unlike that of ordinary rickets. The bone itself also showed a general osteoporosis and the deformities present were largely due to bending of the bone.

Dr. Parsons said that two apparently contradictory results had emerged from a study of these cases—namely, that in the florid and atrophic types cure might occur, but in the woolly type the use of ultra-violet rays made the condition worse. In all types of renal rickets the blood phosphorus was high. The calcium varied from 7·5 mg. to 11 mg. per 100 c.cm. ; compared with the phosphorus it was, therefore, always relatively low, although the actual figure might be normal or even above normal. In the atrophic type cure at the age of 16 or 17 years was probably due to the period of growth being over. The probable mechanism of cure in the florid case shown was as follows. When the child came under observation first it was in an attack of uræmia, and as a result the phosphorus reached a very high figure. As the child improved the kidney was able to excrete phosphorus better and the calcium thereby became relatively higher and eventually, when cure had occurred, the calcium and phosphorus were almost in the same ratio as in the normal child. The picture presented by the woolly type was exactly that seen in the low calcium rickets produced experimentally in rats, and the histological picture, although not identical with that usually seen, undoubtedly indicated rickets. The woolly type was the most severe type of the condition and the reason why ultra-violet rays were contra-indicated in treatment, particularly of this type, was that the effect of ultra-violet irradiation was to increase the already high blood phosphorus, thereby making the already relatively low calcium lower still.

Dr. L. BALL showed a case of

Myelitis with Optic Neuritis.

The patient was a boy, who was admitted to hospital in June, 1923, being then 4 years of age. A febrile illness had commenced on May 16th of that year, accompanied by severe pains in the back and legs. This was followed by paralysis of the lower extremities, which developed gradually during a month from the onset of the illness, by which time complete flaccid paralysis of the lower extremities was present with anæsthesia and retention of urine. About six weeks after the onset bilateral optic neuritis developed, rapidly producing total blindness. The flaccid paralysis of the legs gradually passed into a spastic paralysis with contracture. The anæsthesia and the bladder paralysis recovered. The optic neuritis subsided into a post-neuritic atrophy, and to-day the discs showed atrophy of the so-called primary type. There was total blindness.

Dr. Ball also showed two cases of

Post-Encephalitic Respiratory Disturbances.

In the first case encephalitis developed during an attack of scarlet fever in 1924. In July, 1925, the child showed very marked attacks of respiratory disturbance, in which she went black in the face. Since then the attacks had slowly but steadily decreased in severity, duration, and frequency. She now had a definite Parkinsonian gait and attitude, but only a very occasional respiratory attack.

The second case was that of a female child who three years ago had an illness which commenced as an influenza cold, after which she became very restless, "like St. Vitus' dance," and was continuously picking things and chattering. This phase lasted three days, after which she became very drowsy and slept practically continuously for a fortnight. During this time a squint was noticed. She then became restless again, particularly during the night. The restlessness was now less marked, but for the last nine months she had panted. Occasionally she had turns of going black in the face, after which she slept. She was sleepless at night and had dribbled ever since the onset of the illness.

Dr. K. D. WILKINSON showed a case of a child, now aged 17, with

Congenital Heart-block.

She was first seen five years ago, when she exhibited a slow pulse, with no history of a previous illness. The heart was enlarged and there was a systolic murmur at the apex. The Wassermann reaction was negative. He had taken a number of electrocardiograph tracings which showed a complete heart-block. The pulse was usually about 32 ; to-day it was about 44 ; probably this was due to the fact that in these congenital cases excitement and exertion had some effect in increasing the ventricular rate. He believed the prognosis to be good.

Another case shown by Dr. Wilkinson was one of chronic nephritis, the particular interest of which was the recovery from a severe and protracted uræmia.

This girl had scarlet fever when 3 years old, and was first admitted to hospital in 1924 with heavy albuminuria and casts, but a normal blood-urea. Twelve months later she was readmitted with vomiting and oliguria and a blood-urea of 140 mg. per 100 c.cm. In September, 1926, she developed uræmia. The blood-urea was then 278 mg. per 100 c.cm. She remained in a uræmic state for over a fortnight, with a blood-urea consistently over 200 mg. per 100 c.cm., although the urinary output increased. Thereafter she made a slow recovery, interrupted only by a few minor remissions, until at the present time the blood-urea was only 53 per 100 c.cm., the blood pressure was normal, and the urinary output averaged 35 to 40 oz. in the 24 hours.

Dr. Wilkinson also demonstrated a case of Congenital Heart in a Child aged 9 years.

The child had been blue from birth, was breathless on exertion, had suffered from frequent attacks of bronchitis, and occasionally from epistaxis and hæmoptysis. There was slight cardiac enlargement to the left, but none to the right, and a systolic murmur at all areas. Extreme clubbing of the fingers and toes was present and the red cell count was over 9 millions.

Dr. Wilkinson said that these should be regarded as cases of a disease not so much of the heart as of the circulation. The prognosis depended on three things —clubbing of the fingers, cyanosis, and polycythæmia.

Mr. SEYMOUR BARLING showed a case of

Œsophageal Spasm

in a child aged 4 years.

She had had persistent daily vomiting, without nausea, for years. After giving her a barium meal the X ray

examination showed an œsophageal spasm 2 in. above the diaphragm, and the question arose as to what was the nature of the condition. The barium remained in the œsophagus two to three hours, and some was persistently present for ten days. During her stay in hospital she put on a little weight, but still continued to vomit, and she could only take semi-solids. Examination by the œsophagoscope showed that there was no ulceration of the œsophagus, but that the condition was one of spasm. A bougie passed easily, but the spasm nevertheless continued.

Mr. Barling thought there seemed to be some similarity in this condition to cardiospasm in adults. Although cardiospasm was rarely seen in children, he wondered if this case was not really an early stage of that condition, and if the œsophagus would become dilated as the child grew. At the present time he was trying treatment with Souttar's tube and would welcome any suggestions as to treatment by other methods.

D. J. G. EMANUEL showed the case of a child suffering from

Polycystic Disease of the Peritoneal Cavity

of unknown origin.

The patient was a girl aged 9, who was normal up to the age of 1 year, when her abdomen began to swell, and at 3 years of age she was admitted to hospital with an abdomen of 27 inches in circumference and with a diagnosis of ascites. The abdomen was tapped and 3½ pints of dark-coloured fluid was withdrawn. The child left the hospital with an abdominal girth of 25 in. From this time onwards the abdomen continued to increase in size until the girth reached 38½ in., but her general health was unimpaired. In July, 1926, the abdomen was opened in the middle line and a large cyst exposed. This cyst contained about six pints of olive-green fluid, with many cholesterin crystals in suspension. Similar cysts, varying in size from that of a large orange to cysts containing several pints of fluid were found to extend throughout the peritoneal cavity, from the under-surface of the diaphragm on both sides down into the pelvis. Many cysts were incised, but removal was not found to be possible.

No indication as to the origin of the cysts was obtained, said Dr. Emanuel, but the structure was not that of hydatid cysts. He thought, however, that it might be a multilocular ovarian cyst.

Dr. P. C. CLOAKE showed a case of

Hemiplegia Occurring During Diphtheria.

The patient was a girl aged 12, who was admitted to an isolation hospital in June, 1925, with diphtheria. After 14 days in hospital she had apparently recovered from the illness, when she was seized with a right-sided hemiplegia and asphasia, and became very ill. Two weeks later she developed severe attacks of vomiting and, later still, difficulty in swallowing, probably due to pharyngeal and palatal palsy. There was some recovery of aphasia and of the right leg, but as was usual in these cases the right hand was still very spastic.

In the opinion of Dr. Cloake the condition was not due to an encephalitis, but to embolic impact of the brain. The source of the embolus was probably a clot in the left ventricle.

Two Interesting Cases.

Dr. J. M. SMELLIE showed two cases.

The first was a girl aged 12, who was admitted to hospital in 1919 with enlarged liver, a large heart, and a history of œdema. She was admitted to hospital again recently. On examination the child showed marked stunting of growth, and in the abdomen were three or four large irregular masses, but no symptoms of any kind were complained of. There was no evidence of deficient fat absorption from the bowel, and kidney efficiency tests were normal. The blood showed a normal count, and radiological examination did not show any displacement or deformity of the stomach, or intestinal stasis. The Wassermann reaction was weakly positive.

Dr. Smellie thought the case was one of tuberculous peritonitis, but hydatid cysts had also been suggested as an explanation of the abdominal tumours.

The second case was that of a boy aged 12 years, who appeared normal at birth, but was very late in learning to walk owing to marked spasticity. For the last three years the patient had been unable to feed himself because of marked tremor of the arms. Several operations had been performed on the legs to enable him to stand and walk with the aid of splints. At the present time the boy showed marked general spasticity, was unable to walk or stand alone, and there were coarse tremors made worse by voluntary movement. Marked dysarthria and some incoördination of the movements of swallowing were present. The tendon reflexes were increased, there was primary optic atrophy, and no pupillary light reflex. The liver was not enlarged, and van den Bergh's test was normal. The Wassermann reaction was negative. The child was not mentally defective, but he was subject to spasmodic attacks of laughter.

Dr. Smellie said that he had only had this case under observation for a short time, and he wondered if the condition might not be lenticular degeneration. Many of the symptoms suggested that condition, but the child had a double optic atrophy, and Dr. Beatson Hird had examined the eye with a slit lamp and reported that there was no Kayser-Fleischer ring present.

Pathological and Biochemical Illustrations.

After the clinical cases had been discussed there was a pathological and biochemical demonstration. Specimens illustrating hepatic lesions in childhood were shown by Prof. HASWELL WILSON. Specimens showing results of caseation of mediastinal glands by Dr. SMELLIE. A specimen of actinomycosis of the liver by Dr. BALL, and Dr. W. J. HILLIER gave a demonstration of his methods for testing the fragility of the red blood corpuscles, and of estimating the coagulation-time of blood. In the biochemical laboratory Dr. E. M. HICKMANS showed methods of estimating the colloidal osmotic pressure of blood, the estimation of blood cholesterol, the manufacture of lactalbumin, and the method of irradiating cholesterol.

LONDON POST-GRADUATE HOSTEL.

AT the bi-weekly discussion on Oct. 28th Mr. F. N. DOUBLEDAY, the President, opened a symposium on the

Filled Tooth as a Source of Streptococcal Blood Infection.

Some people, he said, have scoffed at the idea that a dead tooth could have any direct relationship with general disease, while others, in the opposite camp, laboured under a wish to extract every tooth from the patient's mouth, whether dead or healthy. Dental surgeons saw many people who suffered from a mass infection, such as pyorrhœa, but that was not the particular subject chosen for discussion; it was the dead tooth as a source of general streptococcal infection. He asked that the debate be confined to the streptococcal variety of invasion. The discussion naturally fell under two main lines: First, the pathological part—i.e., the establishment of the fact that the infection was there; secondly, the paths through which the infection probably travelled to become manifest in remote parts of the body. Perhaps opinions would be expressed on the recent work done in America by Weston Price, and the views held by Rosenow on the election shown by certain organisms for particular parts of the body. Dr. Weston Price had been doing work on the granulomata which occurred at the apices of teeth. Those who cut such granulomata open were aware that they were frequently found to be solid masses of cells, and many knew that they contained large numbers of leucocytes, which helped to give them their solid character. Weston Price's suggestion was that many of these solid granulomata at the apices showed in the skiagram as rarefied areas, and he believed that they were not so much evidences of infection as manifestations of the reaction of the body to the tooth condition, that they were, really, evidences of defence. Mr. Doubleday proceeded to mention three illustrative cases of proved streptococcal infection from his own practice.

The first was that of a married woman, aged 35, who came for treatment seven years ago and showed a tendency towards synovitis; she had teno-synovitis in the tendons of the arms and wrists. There were three dead teeth and a good deal of gum infection. He tried to persuade her to part with her dead teeth, but she steadily refused to do so, and went away for six months. At the end of that time she returned, suffering from acute teno-synovitis, and again he tried to get her to have the dead teeth extracted and the

others too, as streptococci had been grown from her gum margin. Her own local dentist scoffed at any measure beyond extraction of the three dead teeth. After that was done the teno-synovitis cleared up, though there were still streptococci at the gum margins.

The second patient, also a woman, was aged 65, and she had myositis, and arthritis of the cervical vertebræ, leading to much stiffness and limitation of movement, especially on turning her head. She also had some dead teeth, from which streptococci were cultivated. After those teeth had been removed she got some recovery of the movements which had been sol imited, but was disappointed because she did not get complete freedom following the extractions.

The third case was that of an ex-officer, aged 45, who two years ago was suffering from sciatica of a very acute form. He had two dead teeth, one of which, after it had been extracted, yielded from its apex *Streptococcus longus* almost in pure culture. The socket did not heal very well after the removal, and whenever there was a collection of leucocytes, with some pus, in the socket he suffered an exacerbation of the sciatica, and it was necessary in order to relieve the acute pain to open up and drain the socket. There was thus proved to be a close association between the sciatica pain and the condition of the tooth socket; even light treatment and the use of vaccines had failed to relieve the pain in the absence of the local measures referred to.

The Dental Aspect.

Mr. E. SPRAWSON spoke of the various causes of teeth going dead after filling. He said that, ordinarily, the death of tooth pulp was a process attended by some pain, and occasionally by considerable pain; but, under certain circumstances, neither pain nor any other symptoms accompanied it. One cause of the death of tooth pulp was that certain filling material used was harmful to the pulp; some of the synthetic compounds might cause such death by their toxic products passing down the permeable tooth into the dentine. Before the dental surgeon put in any such filling he should line the cavity with an impermeable cement; then such toxic effect could not ensue. Certain drugs were occasionally used by dental surgeons for the purpose of lessening the sensitiveness of the dentine when they were preparing cavities. The chief of these were arsenic and paraform, and, more rarely, ethyl chloride. These might kill the pulp without pain being felt, and micro-organisms might have been left in the cavity at its preparation and might subsequently cause a more general infection. An important point was that though the filling used in a tooth might be sound and good, yet on some aspect of the tooth not easily seen, where it was adjacent to another tooth, a new site of caries, unsuspected, might have occurred, and result in infection and the death of the tooth. This death usually caused pain, but it must be remembered that occasionally it did not. Sometimes, notably in children, when excavating the cavity the surgeon might expose one or more cornua of the pulp, perhaps with the last stroke of the burr, and an attempt was often made to preserve tooth pulps by sterilising the cavity and covering over the exposed cornu with some non-irritant, slightly antiseptic dressing. In adults this frequently was not successful. Senile teeth (by which he did not mean the teeth of old people) were often found to have dead pulp, and often there was present some recession of the gum. Therefore, at the outset, such a tooth should not be saved; some infection might be left in the depths of the cavity at the time of its preparation for filling. The tooth pulp might be killed in operations on the maxillary antrum, especially when an opening was made through the canine fossa, with the consequent cutting off of the nerve and blood-supply. Also, trauma might cause the death of the pulp, whether or not filling had been done. When the dental surgeon had to deal with sensitive dentine he sometimes injected a local anæsthetic into the gum in the proximity so as to lessen the sensitiveness of the dentine, and usually some adrenalin was used at the same time, and thereby the pulp was rendered not only anæsthetic but analgesic. As soon as the effect of the anæsthetic had worn off, the patient could be depended upon to let the dentist know about the pain.

The Radiological Aspect.

Dr. A. C. JORDAN demonstrated on the screen a series of radiographs of the teeth and jaws, both healthy and in various stages of disease. He said that X ray films were essential to the diagnosis of infected roots, as neither doctor nor dentist could be sure of the diagnosis without them. In all civilised communities teeth decayed early, chiefly because of the unnatural condition of the foods eaten. If people were to return to eating fruits, nuts, grains, and greens, with fresh farm produce, the teeth as a whole would be immensely better in a single generation, especially if careful attention were given in the matter to the expectant mother. During the months of nursing and a year beyond, infants should be encouraged to work their jaw muscles by biting on bone and other hard substances, as this tended to allow more room for the teeth when they came, and to avoid overcrowding. The sucking of "dummies" should certainly be discouraged, as this contracted the jaws.

The Bacteriological Aspect.

Dr. R. G. CANTI said that normally the mouth was crowded with organisms of many kinds; a cubic centimetre of saliva contained 100 million cocci. Therefore it was easy to contaminate cultures when material was taken from the mouth for investigation. There were two important sites of sepsis: the pyorrhœa pocket, and the apex of the tooth, the latter being the more important. The mucous membrane of the mouth was continuous with the periodontal membrane, and when that membrane was the seat of disease any organism inhabiting the mouth could get down there and destroy it, forming a pocket which was the nidus of infection. Some of the mouth organisms lived there as saprophytes, but others produced toxins, which were very liable to be swallowed and do harm in the intestinal tract. Usually streptococci were not predominant among the mouth organisms; more frequent denizens were Gram-negative organisms, such as coliform or highly motile vibrios. Spirochætes also were present in large numbers, as well as amœbæ. He had never examined pus from a pyorrhœa patient without finding the latter. Sometimes an organism from outside was found in the pus of a pyorrhœa case, such an one being actinomyces. There were many difficulties connected with the bacteriological examination of the contents of an apical abscess. The tooth could be extracted and an attempt made to grow organisms from the root. But there were fallacies to beware of. As the tooth was being drawn from its socket the tendency to form a vacuum resulted in movable material, such as saliva, being drawn into the cavity and vitiating the examination. He deprecated the practice of putting a tooth into a bottle with its matter round it, for the result of 12 hours of shaking up in the post was that all the other material had got into the apex, and a dependable opinion could not be given. Much help could be afforded by sterilising the cavity; iodine should not be used for this, as it was likely to kill bacteria. Alcohol, or alcohol followed by ether, was preferable. The form of streptococcus usually found at the apex was *S. salivarius*, that at the root of an acute abscess a hæmolytic streptococcus.

Discussion.

Mr. A. P. BERTWISTLE gave a résumé of a case of severe constitutional disturbances which cleared up on removal of a tooth and drainage of an abscess.

It was that of a man, aged 29, who had an attack of follicular tonsillitis, and one evening, when it was clearing up, he had pains in the left ankle. On the following day the pain had ceased, but the ankle was swollen, and pitted on pressure being applied. He had "tightening" pains in the lower part of the right chest, and much constitutional disturbance, the temperature being 101·5° F. In six weeks the chest pains had disappeared, but the œdema increased and extended up the leg. A month later the tonsils were removed, and as the appendix became inflamed that was removed four months later. Four years after these occurrences he had erysipelatoid attacks, and in half an hour he had a feeling of malaise and the temperature was 101°, and for 24 hours he had copious vomiting. The inguinal

glands became painful, and the saphenous vein hot and painful, probably part of a lymphatic trouble. Walking was impossible owing to fixation of thigh and knee, but in a month this disability had disappeared. Three further attacks occurred, but the third was much less severe. In a still further attack the leg was tender and all movements of toes and ankle were very painful. Mr. McAdam Eccles saw the case and suggested that a dental focus was the source of the trouble, recommending that the teeth should be X rayed. An abscess at the root of the second molar tooth was subsequently found, and on an apparently perfect filling being removed, pus welled up. A strong antiseptic dressing was applied to the tooth, and following that the patient's condition was much improved. As there had been no pain in the tooth, it was a surprise when an abscess was discovered.

Mr. W. MCADAM ECCLES said surgeons came across many cases of the kind in which the source of infection was very difficult to find. The late Mr. Lockwood was one of the first to draw attention, in any London medical school, to the fact that the mouth contained a vast variety of bacteria, and even animal parasites, and that these might be the cause of many of the conditions which were found. In the definite condition which might be called pseudo-elephantiasis, in which the lower extremities were very much enlarged, particularly below the knee, with a peculiar sulcus about the ankle-joint, giving rise to what might be termed "tortoise-foot," there was often a definite source of infection in one or more teeth, especially teeth which had been stopped or crowned. And, in most of the instances, the removal of those infected teeth had produced very considerable improvement in what might be termed the secondary characters of such pseudo-elephantiasis—namely, the continued breaking and cracking of the hard, coarse skin.

Dr. P. H. MANSON-BAHR spoke on the subject of elephantiasis, the tropical disease, which might or might not be associated with chronic sepsis. He did some research work on this disease 15 years ago. It was a widespread disease, especially in some of the Pacific Islands; sometimes 20 per cent. of the inhabitants of an island were afflicted with the disorder. The filaria parasite was its first cause in natives, but it was not held that the filaria alone was responsible for the disease, as people could be infected with many filariæ for many years without having signs of lymphatic obstruction. In the production of the disease the filaria worm and the streptococcus worked hand-in-hand. In this country one saw instances of elephantiasis nostras, usually associated with recurrent attacks of lymphangitis, and there was always present an ascertainable cause of sepsis. In this the filaria worm was not operative, as it was not found in this country. In some cases of elephantiasis nostras one could find not only dental sepsis, but also some raw skin lesion or surface of the body from which toxins could be absorbed. Some of the cases started insidiously, without any exacerbation, that then it was very difficult to know what the cause of the infection was. An allied condition was congenital lymphœdema, of which he would like to know the cause. It was supposed to be a progressive stenosis of the main lymphatic trunks, and he did not think it could be attributed to any focal infection.

MANCHESTER MEDICAL SOCIETY.

A MEETING of this Society was held on Oct. 6th, when Dr. ALFRED A. MUMFORD delivered the presidential address on

Physique, Stamina, and Efficiency of School-boys.

He said that though we had vastly improved the medical assessment of health during the last 90 years, yet the methods of measuring physique advised by the medical witnesses during the Factory Commissions —the measuring rod, the scales, the tape, and the pulmometer of Thackrah, and the date of eruption of the permanent teeth introduced by Sir E. Saunders —still constituted the basis of our judgment of the physique of the school-boy. In all our calculations it was necessary to begin with the average boy and from him measure accelerated or retarded physique, the effect of instruction in the gymnasium, swimming-bath, games, and class-rooms. In the investigations described inquiries had been extended to the comparison of school physique with subsequent career at the local university. The Manchester Grammar School measurements had been taken under exactly the same conditions of clothing, &c., from 1881 to the present time. They showed that the average boy was steadily improving in height, weight, and chest girth, though the measurement of vital capacity and of endurance (by Flack's test) had been of too recent adoption for us to be able to tell whether there was any improvement in respiratory power. Measurements of boys admitted to the Classical VI. and Science VI. between 1890 and 1910, and of boys chosen for the gymnasium eights during the same period showed that, while there is little to distinguish them in height or weight from the average boy, yet in both cases there is a significant difference between them and the normal boy as regards chest girth. In order to find a common basis for comparing mental and physical progress, units of physical measurements must be taken on time increments—that is, in the progress made in six or 12 months. Tables of time-increments in height, weight, chest girth, vital capacity, and endurance based upon the records of the school had been drawn up and were used for constant reference. By means of these the relative development in the different categories could be compared. Observations were also made on the specific gravity of boys in the school swimming-bath during the summers of 1923–24. It was found that the largest factor in the variations was due to the degree of inflation and the size of the chest. When the means of the observations with inflated chest at each year of life were taken, it was found that they were always below that of water, while the means of the observations with deflated chests were always above that of water. The question of buoyancy as a standard of health was, therefore, considered. As it was impossible to measure the buoyancy of all the boys in the swimming-bath, an attempt was made to utilise the measurements taken in the gymnasium for finding the relation between weight and volume—that is, the specific gravity. The formula

$$\frac{\text{Weight in grammes} \times \text{K}}{\text{Height in centimetres} \times (\text{chest girth in centimetres})^2}$$

was adopted.

A lengthy series of inquiries showed that for the average boy "K" was in the immediate neighbourhood of 19·5. In the subsequent 2300 calculations of series of measurements, the "K" was left out and the formula $\frac{W}{H C^2}$ was used as a crude buoyancy index of health. If special cases, where the chest girth differs markedly from the mean circumference of the body—e.g., the cases of boys of exceptional shoulder development and the cases of boys of very full stomach are left out—the crude buoyancy index was a very useful method of testing the physical fitness of different boys. The means of the crude buoyancy index of the 2300 cases at each age were taken as the normal, and it was found that the high level scholar was of markedly greater buoyancy and the gymnasium champion of still greater buoyancy than the average boy of the school. A further series of measurements of shoulder girth was taken and this girth was calculated as a percentage of the trunk height in order to obtain an index of shoulder development.

A study of the development of the shoulder in relation to physique was of very great importance, since in Circular 1363 the Board of Education virtually scrapped the elastic horizontal ladder, the row of rings, parallel bars, and horizontal bar which had played so large a part in developing the physique and courage of English public school-boys, in favour of Swedish apparatus. Mathematical analysis of measurements taken at the Manchester Grammar School

showed a high correlation between the development of the shoulder as secured by English methods and the high range of breathing. Whether Swedish methods would prove as active and beneficial to English public school-boys remained to be proved.

Graphs illustrating the way in which the development of champion gymnasts, swimmers, winners in long-distance runs, sprinters, holders of school colours in lacrosse, football and cricket, and also graphs showing differences in physique between boys of accelerated and boys of retarded scholarship had been constructed. Finally, a group had been taken of 140 students who during the last ten years had been educated at the Manchester Grammar School where they had been submitted to periodic measurements and had subsequently passed on to the Manchester University. The group was divided into two sections: (1) about 45 in number who had passed through a five years' course at the medical school and had not failed at any examination, and (2) those who had suffered one or more failure. It was found that, though the mean height after 16 years of age in the former group had been slightly less than the mean of the latter group, yet when the relative gradings in height, weight, and chest girths were compared, the boys who had passed through the university without any failures had shown an ampler range of breathing or a larger chest girth in relation to their height than the group who had suffered failure.

INTERNATIONAL SOCIETY OF MEDICAL HYDROLOGY.

AMSTERDAM CONFERENCE ON CHRONIC RHEUMATISM.

By invitation of the Dutch Committee of the Society a conference on rheumatism was held at Amsterdam on Oct. 23rd, representatives of the Ministry of Health, the British Red Cross Society, the Society's British Committee on Rheumatism, the British Spas, and the Spa Federation being present. The morning was spent at the Institute for Physical Treatment (Keizersgracht 489) where the medical director, Dr. J. VAN BREEMEN, secretary of the Dutch Committee, demonstrated the methods of physical treatment as applied in rheumatic and circulatory disorders to insured patients of whom as many as 300 may be treated in one day. The conference took place at the Colonial Institute, about 900 persons being present, Dr. TREUB, Chairman of the Dutch Committee, presiding.

Prof. J. R. SLOTEMAKER DE BRUINE (Minister of Labour), who officially welcomed the guests, expressed a hope that Holland would prepare statistics of the incidence of rheumatism similar to those published by the British Ministry of Health. The Dutch Government, he said, had every desire to support this movement.

Dr. TREUB said that the neglect of the study of common rheumatic disorders and the absence of clear data was bad alike for the patient and for the community. In Holland there were large numbers of workers suffering from rheumatic invalidity. Dr. van Breemen was their medical consultant, and they hoped to establish a special hospital for rheumatism in Amsterdam at an early date. A national effort was needed to combat these diseases.

Dr. FORTESCUE FOX (London) recalled the annual summer migrations of Highland fisher folk to the spa and the obvious relief thus obtained by people who lived in a cold and damp country. He was convinced that this age-long popular usage was justified, for modern medical observation had only confirmed the universal experience of the value of baths and internal treatment by waters in chronic rheumatic affections. But these natural physical remedies, if they were to be used with any advantage in our present civilised life, must be given by practitioners of special training and experience. Recent reports from northern European countries had brought out the dependence of the rheumatic diseases upon physical influences. The Council of the International Society, which had more than 300 members, believed that investigation ought to go hand in hand with curative measures, as had been done in the disablement clinics established during the war. Committees set up by the Society in northern European countries had recommended that treatment for rheumatic industrial workers should be improved both in quantity and quality, and concurrent investigation and treatment, under skilled medical direction, was the watchword of their movement. The problem in England and Holland was similar, because natural baths did not exist in Holland and were insufficient in England to deal with the large numbers involved. In England it was proposed to develop the facilities at the spas, and to set up clinics in the towns for investigation and treatment. During the last half century physical treatment had developed more upon the continent than in England; the British delegates welcomed the opportunity of studying methods at the Amsterdam clinic, and were also visiting the Hospital for Rheumatism at Aachen, directed by Dr. Krebs. They were dealing with a group of disabling diseases which inflicted serious economic loss upon all the northern communities, and it was essential that they should join forces in a common effort.

Dr. ALISON GLOVER (British Ministry of Health) said that the importance of rheumatic disease was everywhere admitted, and had been clearly shown 16 years ago in the admirable statistics of the Leipzig Federation of Sickness Funds and more recently in Sweden by Dr. Kahlmeter. The report of the British Ministry of Health showed that nearly one-sixth of the total sick pay for industrial invalidity was paid on account of these so-called rheumatic diseases, and this great incidence might be accepted as proved, at least for northern Europe. Most people were agreed that, at all events in England, only a minority of these hosts of patients were able to secure those forms of treatment which were highly beneficial if not essential; only a minority were subjected to that thorough search for the focus of infection which was so often required, and only a very small minority, usually of the better class, received appropriate physical treatment. Sir George Newman, the Chief Medical Officer of the Ministry, had repeatedly urged the necessity for provision of further treatment, and had pointed out that even with present knowledge an immense amount could be done, and ought to be done, for patients with such diseases as rheumatoid arthritis. Institutions for such treatment, he had said, should not be regarded as a Utopian ideal, and might, indeed, represent an economy, in view of the large sums which were now being spent or lost yearly, whilst allowing these diseases to progress unchecked by the kind of treatment they required—treatment which often could not be provided by the practitioner alone, nor, indeed, by the ordinary hospital or infirmary.

More recently, continued Dr. Glover, the same authority had foreshadowed a scheme which would include three different types of institution, the first being the *Physical Treatment Clinic*. Such clinics would serve a threefold purpose; first, they would be clearing houses, directing patients to the form and place of treatment suited to their need; some would be sent for spa treatment, some for intensive study at an arthritis unit, whilst others would be greatly benefited by treatment at the clinic itself. Secondly, therefore, these clinics would be out-patient institutions, to supply those forms of physical treatment often necessary for the re-education of muscles and joints. Thirdly, they should be organised in close coöperation with the arthritis unit and with the spa hospital, and provide continued supervision, observation, and after-care, following institutional treatment. Such clinics would be also of great service in diseases and conditions other than rheumatic, such as fractures, deformities, and diseases of the nervous system. The second type of institution foreshadowed was the *Arthritis Unit*, which should be in closest coöperation with a large teaching school of medicine or university, enabling it to fulfil

the purposes of research and observation as well as teaching. It would also act as a place of preliminary treatment or preparation for spa treatment. Patients would be admitted at the earliest possible stage of their disease for thorough examination by modern methods. The focus of infection would, if possible, be found and removed; bacteriological and biochemical investigations would be completed, and a diagnosis made before the patient was passed on to another institution; orthopædic surgery would, if necessary, be used. Such a unit would furnish opportunity for team-work in both research and treatment. The third type of institution was the *Spa Hospital*, organised in closest coöperation both with the arthritis unit and with the physical treatment centre. The hospitals at Bath, Buxton, and Harrogate suffered at present from the fact that many of their 650 beds were occupied by advanced cases. A wise selection of cases would be invaluable to the efficiency of the spa hospital. The patients having been thoroughly examined and the preliminary treatment being completed at the arthritis unit, spa treatment would be much more beneficial and the duties of the spa physician simplified.

Dr. KREBS described the treatment of insured rheumatic patients at the Landesbad at Aachen,

Dr. VAN BREEMEN protested against the common opinion, even in medical circles, that the control of rheumatic diseases was impossible. Many facts had been published and many results put on record by well-known medical men, proving that successful treatment was possible, even with the present poor organisation. He believed that when the family doctor had received at the university medical education in the diagnosis and treatment of rheumatism the results would be much better. But more was required than the family doctor in contending against these diseases. A special hospital for rheumatism was needed with a laboratory for scientific study. It had been demonstrated, especially in America during the last 25 years, that hospitals for particular diseases were of great advantage to the patients and to science. Holland might be made an important centre for the study of the rheumatic diseases, but both energy and funds were needed for this purpose. Moreover, he said, every disease with a social significance must be fought at the beginning and not at the end.

On the following day the conference was resumed at Aachen, where Dr. Krebs and his assistants demonstrated the organisation of the Landesbad, erected by the Friendly Societies of the Rhine Provinces in 1912, for the use of their members suffering from rheumatic diseases. The cases, usually in an early stage of disease, are selected by a commission at Düsseldorf. There are 360 beds and a complete system of physical treatment.

Reports and Analytical Records.

PREPARED HONEY (EMPIRE PRODUCE).

(GARVIN BROS., LTD., 26, FINSBURY-SQUARE, E.C. 2.)

THIS prepared honey is stated to be a blend of honeys of the Empire, "to which has been added the necessary proportion of invert sugar (the natural sugar of ordinary honey) to secure a uniformly high quality and mellow flavour." It is, therefore, obvious that this "prepared honey" is an admixture of ordinary honey and invert sugar. When analysed the following results were obtained:—

Invert sugar	71·05 per cent.
Cane sugar	3·10 ,,
Water	20·30 ,,
Ash	0·14 ,,
Unestimated matter (wax, proteins, &c.)	5·41 ,,

This composition closely approximates that of ordinary genuine honey, but is rather sweeter to the palate. It may be regarded as a wholesome preparation, and the food value is comparable with that of pure honey.

Reviews and Notices of Books.

OBSTETRICS.

By JOHN S. FAIRBAIRN, B.Ch. Oxf., F.R.C.P. Lond., F.R.C.S. Eng., Obstetric Physician to St. Thomas's Hospital. London: Humphrey Milford, Oxford University Press. 1926. Pp. 221. 5*s*.

THE common purpose of the Oxford Medical Handbooks, to which series this volume belongs, is to deal shortly with the fundamental principles which underlie their subjects, and to illustrate these by their applications in general practice. The handbooks are not intended to be short text-books, but to give a general survey, on broad lines, of various branches of medical science and of their inter-relations with each other. Dr. Fairbairn has shown that a survey of so complex a subject as obstetrics can be compressed into some 200 small pages by a master-hand without any important aspect being ignored. No attempt is made to mention the rarer abnormalities and difficulties of obstetrics, so that plenty of space remains to deal thoroughly with essentials. The result is most pleasing. Instead of a dull cram-book we have here a delightful expression of the author's broad outlook on obstetrics in relation to public health and private life. It is unnecessary to add that the teaching is up to date; for example, the latest views of Treacher on the imbedding of the ovum are included. The chapter on the Place of Obstetrics in Medicine and the Public Health Service is admirable, and the whole book is pervaded by that common-sense view of the subject which so many text-books appear to lack.

In the preface the author modestly suggests that the book should be useful as a primer for students; we would add that all who take an active part in obstetrics could study it with advantage.

PUERPERAL SEPTICÆMIA.

By GEORGE GEDDES, M.D., C.M. Aberd. Bristol: John Wright and Sons, Ltd. 1926. Pp. 200. 12*s*. 6*d*.

IN June, 1924, the Royal Society of Medicine awarded the Nichols Prize on the best contribution towards the Discovery of the Causes and Prevention of Death in Childbirth from Septicæmia to Dr. George Geddes, of Heywood, who has now published the subject of his thesis in book form. The greater part of the monograph is devoted to the causes and prevention of puerperal septicæmia, symptoms and treatment being dealt with more briefly. The data obtained for this essay are based on the author's 25 years' experience of general practice in one of the industrial areas of Lancashire. Previously he had practised in Scotland, where in his experience the disease was almost non-existent, and it was this marked contrast of the two practices which led to the present investigation.

Dr. Geddes admits many factors as responsible for puerperal fever, and sets out to prove "that industrial accidents determine the puerperal fever rate in every district, because such accidents generally produce septic wounds. He assumes for his purpose that "accident" and "septic wound" are synonymous terms, forming a unit when considered in their relationship to puerperal fever, and holds that septic wounds resulting from accidents become sources of infection. Women in labour are infected, he believes, through the agency of medical practitioners generally, who cannot escape contamination in the daily routine of industrial practice. The author bases his thesis on an extensive mass of carefully prepared statistical tables which are difficult to assess accurately. The statistical portion of the paper was submitted to Mr. Caradoc Jones, lecturer of social statistics, Liverpool University, who reported that "the results indicate a small positive correlation between the puerperal fever rate and the accident rate, and

between the puerperal fever rate and the erysipelas rate, but, in view of the size of the probable errors, it is not certain that the results obtained are significant." Since the proof of the "industrial accident theory" must largely depend on the statistical findings, Mr. Jones's verdict is not very favourable to its adoption. There is no doubt that widespread sepsis must increase the liability to infection during parturition in those cases where interference is necessary. The author remarks "that the most fertile source of streptococci in puerperal cases is the hands of those who conduct the labour"; the obvious remedy is to reduce this interference to a minimum and this can only be accomplished by efficient antenatal supervision. Unfortunately, Dr. Geddes barely recognises this important adjunct to the art of obstetrics, and in one place states "that antenatal supervision as advocated by Sir George Newman will not affect 75 per cent. of the victims of puerperal sepsis." With this view we cannot agree, and would point out further that his own recommendations are very similar to these official edicts which he rather scorns. In his opinion the one solution of the problem lies in preventing those most in contact with septic wounds—i.e., general medical practitioners—from attending puerperal women. As Dr. Geddes recognises the impractibility of this suggestion, his only alternative is that all labours should be conducted under strictly aseptic conditions—i.e., in lying-in institutions. Apparently no provision is to be made for any adequate antenatal supervision. He lays no stress on seeing the patients early, and in some instances his advice appears a little fortuitous—viz., "one might inquire as to the presence of vaginal discharges" or "if considered necessary the urine should be examined."

Without wishing to detract from a laborious and elaborate contribution to the literature of one of the most elusive diseases which have confronted the medical profession, we find that Dr. Geddes has not brought forward any fresh solutions of difficult problems, and that his thesis remains unproven. If, however, by an interesting investigation carried out under difficult conditions he has succeeded in drawing attention to the appalling maternal mortality in industrial areas, and in securing adequate lying-in accommodation, his work will not have been in vain.

SIR FELIX SEMON.

The Autobiography of Sir Felix Semon, K.C.V.O., M.D., F.R.C.P., Physician Extraordinary to H.M. King Edward VII. Edited by HENRY C. SEMON, M.A., M.D. Oxon., and THOMAS A. MCINTYRE. London: Jarrolds, Ltd. 1926. Pp. 349. 21*s*.

THIS is the interesting autobiography of an interesting man. Sir Felix Semon was not only a great laryngologist and one who raised the position of his specialty in this country to new heights, but he was also a skilled linguist and an accomplished musician, although, sad to say, he confesses that he never succeeded in taking to his heart "those old heroes Bach and Handel." He was a good shot, a keen fisherman, and capital company in all circles, so that his life was a full one, both in his public and private capacities, and its record will be welcome to many.

Sir Felix Semon was born in Danzig in 1849, but his family moved to Berlin in 1852. Here in 1856 he records how his father allowed him to sit up late and how he saw two sights which are among the most memorable recollections of his life—namely, Donati's comet, in 1856, and the great Alexander von Humboldt, who was sitting on a chair in the street looking at the comet through a telescope, and who died in 1859 in his ninetieth year. He received his early education at the Friedrich's Gymnasium in Berlin, which he left when aged 18, entering Heidelberg University in 1868 to study medicine, but a severe fracture of the leg sustained during his first long vacation compelled him to return home, and eventually he matriculated at Berlin. In 1870 his studies were interrupted by the Franco-German War, in which he served as a trooper in a Uhlan regiment, but the collapse of France was so speedy that he was able to return to his studies promptly, and he passed the final examinations in 1874. Then began a year of post-graduate study in Vienna, Paris, and finally London, where he arrived in 1875, and in 1876, after much family opposition, determined to settle as a laryngologist. Undoubtedly he had obtained, even in that stage of his career, an unusually good clinical insight, but he must have owed much to his personal qualities, for from start to finish he never looked back, and his long and arduous struggles to obtain recognition for laryngology as a special branch of surgery met with well-earned success.

Outside of his profession he lived in a delightful millieu of musicians, painters, actors, and authors, while he was recognised throughout by his colleagues as a representative man of science. He became President of the Laryngological Society of London, was elected physician for diseases of the throat at St. Thomas's Hospital, and was appointed Physician Extraordinary to King Edward VII., with whom he was on terms of personal friendship No wonder that his autobiography should be full of good stories in the course of a vivid account of a long life of varied activities. A long chapter is devoted to an account of the sad and somewhat sordid tragedy of the last illness and death of the Emperor Frederick, and will recall to senior readers the acrimonious quarrels that broke out in this country and in Germany around the professional behaviour and clinical performances of the closing scenes. Another most interesting chapter is the one dealing with the position of Semon himself and his compatriots in England during the Great War, when the esteem which Semon enjoyed in this country was well shown by the spontaneous resentment of his scientific colleagues at the action of the German laryngologists in removing his name from the *Internazionales Centralblatt für Laryngologie, Rhinologie, &c.*, of which he was the actual founder. This esteem had been shown publicly five years earlier, when in 1909 he retired from active practice. A banquet in his honour was then held and a testimonial subscribed, when the money was at his own request applied to the endowment of a lectureship at the University of London known as the Semon Lectureship for Laryngology. He died from angina on March 1st, 1921.

Dr. H. C. Semon has done his editing well.

BACTERIOLOGY.

A Manual of Bacteriology, Clinical and Applied. Eighth edition. By R. TANNER HEWLETT, M.D., F.R.C.P., D.P.H. Lond., Emeritus Professor of Bacteriology in the University of London; formerly Professor of Bacteriology and head of the Department of Public Health, King's College. London: J. and A. Churchill. 1926. Pp. 645. 18*s*.

THE fact that a book has been before the public for 28 years and has reached its eighth edition is more potent evidence of its success and popularity than any praise bestowed by a reviewer can be. In the life of a much-revised text-book a period comes when it might be well if the author could discard his old manuscripts and re-write the whole out of his mature experience and without reference to literature. Hewlett's Bacteriology now bears evidence of repeated additions; just as an old building sometimes becomes so hedged about by the subsequent improvements, alterations and additions required by changing times and new generations, that the main lines of the original structure are almost lost. In some ways the book "dates" in spite of its constant revisions, a type of Cambridge rocking microtome, for example, being figured whose manufacture ceased some 15 years ago. Prof. Hewlett has, however, been at great pains to keep up to date and has omitted no contribution to bacteriology of importance within the period covered by the book's existence. At the same time any personal gospel is rather submerged in

the effort to include in all-embracing fashion the results and views of a host of workers, and the student will have some difficulty in deciding between what is accepted teaching and what is much more speculative. This does not lessen its value as a reference for those whom experience has brought critical ability, and to them the book will prove extremely useful as one of the most comprehensive books on bacteriology in the English language.

THE HUMAN CEREBRO-SPINAL FLUID.

Vol. IV. of the publications of the Association for Research in Nervous and Mental Disease, New York. New York: Paul B. Hoeber, Inc. 1926. With 77 illustrations and 58 tables. Pp. 568. $10.

FROM knowledge of previous publications of the Association for Research in Nervous and Mental Disease, reviewed from time to time in the columns of THE LANCET, we expected much of this, their latest contribution, and are not disappointed. There have been a number of books in recent years which have dealt with various aspects of the study of the cerebro-spinal fluid in more or less comprehensive fashion; this volume contains perhaps the best survey of them all. The Editorial Committee claim for it the most up-to-date information, the embodiment of material hitherto difficult of access, and the best current interpretation of both the physiological and pathological sides of the subject. The clinical contributions are based on over 5000 recorded examinations of fluid obtained from every conceivable pathological state.

Authoritative presentments of a surprisingly large number of topics, ranging from the fluid's normal biological, chemical, and physical properties to the diagnostic replacement of the fluid by various agents, crowd the pages; a specially interesting section is concerned with reactions of the fluid in diseases outside the nervous system proper. As may be expected, differences of view and opinion in respect of controversial matters are acknowledged rather than harmonised; the incompleteness of present knowledge as regards the embryogenesis of the fluid and its relation to the vascular system is admitted, as also, indeed, in respect of not a few problems that are here handled with conspicuous scientific caution. The publication forms a standard reference volume and will bear comparison with any of its predecessors in the same field of research.

NERVOUS AND MENTAL DISORDERS.

From Birth through Adolescence. By B. SACHS, M.D., Consulting Neurologist, Mount Sinai and Montefiore Hospitals, New York; and LOUIS HAUSMAN, M.D., Assistant in Neurology, Mount Sinai Hospital. New York: Paul B. Hoeber, Inc. 1926. With 110 illustrations. Pp. 861. $10.

FOUNDED to some extent on Dr. Sachs's well-known treatise on the nervous affections of children, long since out of print, this volume contains an excellent modern account of the subject, well balanced and proportioned in its comprehensiveness. A long section on organic nervous disease is followed by others dealing respectively with functional and toxic diseases, endocrine disorders, vasomotor and trophoneuroses, and mental conditions. To the commoner organic ailments sufficient space is allotted, but rarities are not forgotten; among these are Schilder's encephalitis, Pelizaeus-Merzbacher's disease, and amyotonia congenita. The interest of the senior author in congenital affections is illustrated by the full descriptions of the conditions associated with defective development. From the same pen, also, comes one of the best chapters in the book—viz., that devoted to the normal child and normal youth. In this will be found a wise, thoughtful, and practical examination of the stages and experiences of childhood, of the nursery and the pre-school period, the school age, puberty, and adolescence; and it comprises a sane and fair criticism of the ills attendant on irresponsible application of psycho-analytic methods to youthful minds.

We have formed a high opinion of this compendium of nervous and mental disease as the clinician meets with it in youthful subjects; it embodies rich experience with a wide knowledge of current literature, and should at once take its place in the practitioner's library.

BOOKS ON CHEMISTRY.

An Introduction to Surface Chemistry. By ERIC KEIGHTLEY RIDEAL, Humphrey Owen Jones Lecturer in Physical Chemistry, Cambridge University. Cambridge: At the University Press. 1926. Pp. 336. 18*s.*

THE recognition that most of the phenomena associated with the colloidal state are the outcome of the enormous surface development of matter in this state has directed the attention of physical chemists to a closer study of the kinetics and structure of surfaces. This volume presents an excellent summary of our knowledge of this extensive subject, beginning with an account of surface tensions of liquids and solutions. Successive chapters deal with the characteristics of the various types of solid, liquid, and gaseous interfaces, the important subjects of molecular orientation and the theory of membrane equilibria being well described. The two last chapters are devoted respectively to conditions of stability in suspensions and emulsions, and to gels and hydrated colloids; an interesting account of the various theories concerning the structure of gels and the conditions affecting the swelling of gelatin is included. Throughout the book the subject is treated from a mathematical point of view, and those who are not well versed in mathematics are likely to find it somewhat difficult reading. But a grasp of mathematical principles being almost essential to the understanding of modern physical chemistry it serves no good purpose to gloss over this fact even in a volume designed as an introduction to its study. Those who make the effort to brush up their mathematics will be well rewarded.

A Text-book of Organic Chemistry, Historical, Structural, and Economic. By JOHN READ, M.A., Ph.D., B.Sc., Professor of Chemistry in the University of St. Andrews. London: G. Bell and Sons, Ltd. 1926. Pp. 680. 12*s.* 6*d.*

Prof. Read holds the view that by the time the student is ripe for the study of organic chemistry, having mastered the fundamental principles of inorganic and physical chemistry, he should be interested in the historical development of the subject. The author has therefore taken the unusual step of introducing into a text-book of organic chemistry a résumé of the development of chemistry from the earliest times—600 B.C. up to the formulation of the theory of molecular configuration by van't Hoff and Le Bel in 1874. Whether this is the right place for such an account is a matter of opinion, but the author has evidently taken pleasure in writing it, and this is perhaps the chief reason why it was included. The remainder of the book is divided into three parts, devoted to molecular diagnosis, aliphatic and cyclic compounds respectively. The book is written in a manner calculated to arouse in the student a living interest in the subject, since emphasis is laid on the technical and economic aspects as well as the purely academic. To achieve this object the author states that many details usually included in a preliminary account have been omitted. It is doubtful whether, in attempting to make the subject attractive, the author has not offered the beginner too varied a fare. There is much to be said for teaching the young student of organic chemistry not too much, but that right well; it is in his more advanced studies that he will appreciate the relaxation offered by a book of this type.

THE LANCET.

LONDON: SATURDAY, NOVEMBER 6, 1926.

CERTIFICATION AND INSURANCE PRACTICE.

CERTIFICATION is the most criticised of the many duties required of the insurance practitioner. The medical profession contends that the certification rules are unnecessarily onerous, and such an analysis of them as was furnished in our columns recently by Mr. SHOETEN SACK, while going far to simplify the difficulties, must none the less have left the impression that the rules are complicated. The Insurance Acts Committee at a public inquiry have described them as oppressive and menacing, and this expression of opinion was significant because in no other respect has a complaint been made in categorical terms that the duties of the panel are unnecessarily burdensome—arduous as they are, they have been accepted in other directions as unavoidable responsibilities following on the contract. But the medical profession is not the only complaining party in respect of certification, for the approved societies on their side allege that their funds suffer serious loss through loose certification, and panel patients are also embarrassed when these societies demand certificates which the doctors hold that it would be irregular to give in the exact form specified. The position as it affects all the parties should be remembered. To the Annual Conference of Representatives of Local Medical and Panel Committees Sir WALTER KINNEAR said last week that the matter was in the hands of the medical profession, whom he would ask seriously to consider what steps they proposed to take to raise the whole standard of certification; but it is only because the doctor's signature is needed to start what may be an abuse that the doctor can be considered as the only agent in bringing the abuse about. The doctor is not responsible for the whole position. After giving confidential figures showing the increased amount of money disbursed in respect of sickness benefit since the onset of the coal stoppage, Sir WALTER KINNEAR admitted that the Circular issued by the Minister of Health last July, in which the insurance practitioners were asked to exercise the greatest care in granting certificates, had had good effect, in spite of which, however, he said, the increase of the claims continued, being so large now in certain parts of the country that it threatened to place the provision of a specialist service in jeopardy. To that grave position the methods of certification have been undoubtedly contributory, but we must look at the circumstances which have determined those methods.

The amount of money available in any particular year for health service under the National Insurance scheme is a fixed quantity out of which sick pay, medical benefit, and additional benefits have to be met. It is evident that one of these payments can only be increased at the expense of the others, and sick pay, where the amount of sickness or the standard of invalidable sickness has altered appreciably, may easily swallow up the resources. The Controller of the Insurance Department of the Ministry of Health, in which capacity Sir WALTER KINNEAR has spoken, put it to practitioners that, however creditable it might be to their hearts, they would be wrong to regard the Insurance Act as a form of relief, and it would not have been possible to convey the counsel in fairer words. It is evident from information coming in from all sides, as the effect of the industrial position becomes more widely felt, that persons are receiving sick pay who are not entitled to it, and in this way the proper development of the medical service under the Insurance Acts is impeded, because insured persons are being deprived of the chance to secure additional benefits to which they are entitled. A full specialist service when established will cost from 7 to 8 millions sterling in a quinquennial period—that is about £1,500,000 per annum—and the additional benefit schemes already approved under estimate will themselves absorb at once a large proportion of all the distributable surplus. The actual figures given by Sir WALTER KINNEAR show for 13,000,000 insured persons only about 8*s.* per person available for additional benefit each year, and it appears that if the expenditure on sickness benefit is maintained at its present rate it will be impossible to provide the additional benefits contemplated by the Bill now in preparation. One week's additional sickness benefit paid to each person on the sick roll in one year would imply that the additional benefits scheme, which 96 per cent. of the approved societies believed themselves to be in a position to give, will have to be withdrawn; and the specialist service, which all look to as the logical development of an insurance scheme for the health of the people, will not materialise. In face of the seriousness of the facts the Conference carried unanimously a resolution asking the Insurance Acts Committee to consider what practical steps can be taken, while pledging their influence to secure strict adherence to the principles governing certification for the purposes of the Insurance Acts.

The position is clear to every practitioner conscientiously anxious to see a proper development of medical benefit, but it is a terribly difficult course which the medical officer is asked to steer, especially in districts where there is no unemployment pay or where Poor-law relief is very stringently administered. It may be that practitioners are yielding too readily to importunities of insured persons, and where this has occurred the societies have a legitimate cause of complaint, and lax certification may be the root of the evil. But there are circumstances over which practitioners have no control. First there is the actual sickness incidence which may be accidentally or capriciously large; but secondly the social and economic condition of the workers must be reflected in the necessity for medical treatment. Factors in health maintenance due to economic stress cannot be recorded in health statistics, but their existence is known only too well to practitioners and social workers. There may have been no serious epidemics during the particular period at which the ominous rise in the disbursement for sick pay has taken place, but neither the absence of epidemics nor the presence of good weather can prevent the devitalising effects of poverty and hardship. Many practitioners found the demands on their services were greater in the June quarter than in the first quarter of this year, and visiting-lists and surgery day-books

would supply the confirming figures. Further, the figures for the drug bills incurred in the treatment of insured persons would probably bear out the assertion that the amount of treatment given to insured persons, as well as the number of certificates, was in excess of the first quarter of the year. The economic condition of the people has, then, a marked if subtle effect upon the demands of the insured persons. Some of these who keep at work so long as there is work to do are of such poor physique that they fall below a reasonable standard of health when they are unemployed. These men and women can always be considered as suitable cases for certificates when they are out of work. Even the most robust worker after a certain period of unemployment deteriorates rapidly, unless he can find some congenial form of activity. It is only to be expected, therefore, that such an industrial crisis as the coal stoppage will throw a considerable number of the workers on to the sick funds. The industrial dispute has had a demoralising effect on a certain class of workers who have come to regard all forms of assistance—Poor-law relief, strike pay, and insurance benefits—in the same category. It is consoling to find that the approved societies are beginning to realise the effect of the regulation which allows of the immediate transfer of an insured person from the list of one practitioner to that of a neighbour. It was seen from the first that such an adherence to the principle of "free choice" might be used as a method by the disgruntled insured person to find "a nice, kind doctor." By this means undue pressure has been brought to bear upon the practitioner, who, in refusing the certificate, loses his patient. This situation is likely to be changed in the near future by new rules as to immediate transfer.

It may well be doubted whether it is possible or practicable to set up a definite standard of health below which the worker shall be regarded as incapable; it is very difficult even for professional referees to define what they mean by incapacity. Generally speaking, if the exertion necessary to carry on the occupation for the normal hours is likely to aggravate the condition and do physical and bodily harm, the worker cannot be said to be capable of performing the work. Any case whose treatment involves continuous care and supervision cannot go to work. But in estimating the exact right of a particular patient to a particular certificate so much depends on the personalities of doctor and patient that genuine and conscientious opinions cannot be controlled by regulations. We do not want a set of regulations analogous to the excessive prescribing regulations for controlling the number of certificates given. On the other hand, it is not outside the bounds of possibility that the number of certificates of the various practitioners should be compared and some investigations made into the work of those whose figures exceed the district average. The referee work of the regional medical staff has had its effect in cutting down the period of sickness benefit in a proportion of cases, but the feeling ought not to spread among approved societies that if proper certification is wanted they must send every case to the referees, and even this will not have the desired effect unless every case is referred on the initial certificate, which is obviously impossible. Practitioners who have the benefits of the Acts at heart, and who are anxious that the services of specialists should be made available for their insured patients, will exercise all necessary care in a delicate position, but some effort should be made through the panel committees to see that the interpretation of the words "incapable of work" is made more or less uniform in each area.

THE CONTROL OF MALARIA.

AN interesting report [1] on the control of malaria in the plantations of Ceylon has been written by Sir RONALD ROSS, who lately paid a six weeks' visit to the island. It is now many years since he pointed out that elimination of malaria from a district depends on detection of the anopheline vector, and it is a significant commentary on this pronouncement that he was told, when in Ceylon, that all the species of anopheles which are capable of conveying local malaria have not even yet been determined. Everyone is well aware that all attempts to control malaria are necessarily expensive; but, as Sir RONALD ROSS remarks, it is not yet always clearly understood that malaria is expensive too. He gives a striking example of this in a comparison of four contiguous Cingalese estates, where money was lost by failure to tap rubber trees—this failure being attributed to malarial illness. The estates had spleen-rates of 15, 51, 76, and 76. Treating the last two as one the loss of receipts per 1000 blocks of trees, through failure to tap, was in the proportion of 1, 3, and 1000. The total loss for one month only was about £800, quite apart from all expense involved in treating the sick. Ignoring the humanitarian side, the elimination of malaria is financially profitable—a fact which is still far too little appreciated. One of the difficulties, however, is that money must be put down in advance to obtain this prospective improvement, and almost always it has to be borrowed. Loans are none too easy to secure; funds thus raised cannot be lavishly expended, and every penny must do its work. Whilst Sir RONALD ROSS is obviously right in saying that eradication of all anopheles larvæ is an effective means of getting rid of malaria, there are many who will differ from his opinion that too much is made of small differences in the habits of particular kinds of mosquito, because they think that wholesale destruction is more expensive than what is called species sanitation. This last involves close observation of the habits of adults and larvæ of the anopheles locally responsible for conveying malaria, and it seems likely that available money—of which there will be little enough—will increasingly be spent on the specialised destruction of those mosquitoes whose disappearance leads to the greatest financial gain.

The control of malaria in a country where it is prevalent is an undertaking which needs unremitting vigilance. This is perhaps the most important lesson to be learnt from a valuable report [2] recently published by the Malaria Advisory Board of the Federated Malay States. During the year, in spite of all that is being done, there has been an increase in Malaya in the number of malaria cases treated in hospitals—an increase attributed variously to a greater virulence of the parasites and to a large influx of malaria carriers, the result of vigorous recruiting from India. The suggestion that this influx of new blood (in a literal enough sense) is responsible for the increase of malaria falls in with certain findings and conclusions of the Malaria Commission of the League of Nations which recently toured in Eastern Europe. These are that inhabitants of any locality acquire immunity, or at least tolerance, to local strains of malaria parasites; that movements of large bodies of persons, some at least malarially infected, are followed by epidemic malaria—of which the tens of thousands of deaths in

[1] Malaria Control in Ceylon Plantations, a Report to the Ceylon Association, London, by Sir Ronald Ross, K.C.B., F.R.S.

[2] Report for 1925 of the Malaria Advisory Board. Supplement to "F.M.S. Government Gazette," Kuala Lumpur, 1926.

Russia in 1922 is a vivid example—and that these epidemic waves are reasonably attributable to the introduction of strains of malaria parasites to persons who have acquired no special immunity to them. This explanation, however, was not unanimously accepted for Malaya, as it was pointed out that the increase in malarial incidence began in certain estates before there was any increase in recruiting from India.

The Federated States Government has taken a number of immediately practical steps which it is interesting to record. Subsoil drainage pipes, which have been found so necessary in Malaya, are now buried at a minimum depth of 5 feet, and, if possible, 25 feet from trees, and the antimalarial engineer is now investigating the best means of dealing with those penetrating tree roots which may interfere with the proper action of the drains. The Advisory Board has also dealt with another matter of great practical importance—namely, the size of mosquito nets—and has laid down for government institutions minimal measurements of 6½ feet long, 4 feet wide, and 5½ feet high. The emphasis thus laid on the importance of a wide net agrees with, and is perhaps instigated by, H. M HANSCHELL'S observations in Central Africa. The Board advises that where mosquitoes are numerous the lower two or three feet of the net should be made of cloth, so that mosquitoes may be held off by the cloth if the limbs should come into contact with it. The net lies within the posts, is tucked under the mattress, and, during the day time, is drawn back on runners to the head of the bed. This arrangement is the one generally advised at the present day; but if the bed-maker be as trustworthy as the ordinary Indian bearer a yet wider net—trailing on the ground clear of the bed, put up during daylight after the bed has been soundly beaten, and suspended from the walls or roof of room or verandah—will give the added comfort of dispensing with a mattress and the increased protection afforded by its dropping some distance clear of the bed. A solution of magnesium sulphate was mentioned as a recommended mosquito repellent, but no member of the Board had found it, to say the least, lasting in effect, nor discovered anything more satisfactory than citronella oil. Nor did the possible breeding of bats as an anti-mosquito measure find any encouragement. Propaganda on malaria and other diseases has been successfully carried on at the three huge agricultural shows held during the year; the attendance at Kuala Lumpur fair was estimated at 70,000. But, after all, the most useful agents in propaganda are successful results of antimalarial measures, and it is significant that the *kampong* holders of one district have asked for money to embank and drain their compound, undertaking to do the work cheaply and pay the interest on the loan.

PAYING BEDS IN VOLUNTARY HOSPITALS.

THE cost of sojourn in a well-equipped hospital ward has grown steadily during the last 50 years and may, perhaps, now be regarded as having reached a fairly stable figure in the neighbourhood of £2 5s. a week. This at all events is the result of dividing by 52 the average annual cost of maintaining a bed in the voluntary hospitals of England and Wales, excepting the London area. There is a total of nearly 39,000 beds in these general hospitals and another 7300 beds in special hospitals; and in a report [1] which appears this week Mr. R. H. P. ORDE, acting director of Hospital Services for the Joint Red Cross Council, shows that 75 per cent. of the hospitals providing these beds have a credit balance on maintenance account for the year 1925, and their invested funds have increased by £6,000,000 during the last five years. Providing, as they do, facilities for investigation and team treatment not available elsewhere or only available at a very large outlay, it is natural that the demand for beds should become ever more insistent from the side of those who can afford to pay the cost of maintenance plus a fee for medical attendance. Response to this demand has already been made in one way or another at institutions, large and small, scattered over the country. As Mr. ORDE remarks, it is characteristic of the voluntary hospital world that practice precedes theory, and paying beds have been available in the infirmary at Preston since 1876 and at Liverpool since 1887, while at the present moment there are in England 171 provincial hospitals, 27 of them of large scope, which make some provision of this sort. The hope expressed by Mr. A. G. E. SANCTUARY at the Oxford meeting of hospital officers, that the medical profession would combine with hospital managers to expand and remodel the existing system of institutional treatment rather than leave the paying side of the work to be taken up by profit-making concerns, is evidently shared by the whole lay hospital service; the tone of replies received from hospital superintendents and secretaries embodied in an appendix to Mr. ORDE'S report is proof of this. One officer after another remarks on the voluntary hospital being the obvious and best place for any class of patient to be treated in time of acute illness, and several make a point of the permanent friends who would be gained for the hospital by having themselves experienced the amenity and efficiency of its wards. Diversity in the actual arrangements made is healthy enough in giving an opportunity of trying out possible alternatives, but there is a growing unanimity in the broad lines of practice. At Liverpool in 1887 a newly-built block included five one-bed wards, each with its own fireplace, on either side of a private corridor leading to one of the medical wards. At Brighton in 1923 eight single- and six two-bedded rooms were added, controlled and served by the main hospital. At Chester in 1921 private wards were opened in the form of cubicles, extended later into an adjoining wing with separate approach from the main staircase. At Northampton preference is shown for attaching two or more rooms to each ward unit. At Barrow, since 1921, two houses adjoining the hospital have been run as a private nursing home in connexion with it. At Burton-on-Trent a separate block of 18 beds was erected, connected by bridge and balcony to the main hospital, catering being done in the main building. Yeovil remarks on the saving of trouble and expense from having the side wards in the hospital and not in a separate block. Accommodated on one or other of these lines the patient pays from 3 to 7 guineas a week, the tendency being towards a standard fee of 5 guineas. With one or two exceptions the fee for professional attendance is a matter of direct arrangement with the hospital staff or the medical attendant who has sent in the patient. Rarely is inquiry made into private means, although at certain small hospitals fees are fixed by the house committee, and there is talk of appointing an almoner at Brighton. Several hospitals have the pleasing experience that it is unnecessary to do this as all who pay the standard fee augment according to their ability the charge made with a donation to the general hospital funds. It is evidence of this kind, so carefully collected in Mr. ORDE'S report, which enables Sir ARTHUR STANLEY to state in his foreword that there is no question of the call for these beds and to urge that sustained efforts should be made to provide them generally in the voluntary hospitals of the country. This is a development to be considered in the broad scheme of hospital coördination fore-shadowed by the Minister of Health.

[1] Report on the Voluntary Hospitals in Great Britain One of the valuable appendices to this report is printed on p. 986 of the present issue.

Annotations.

"Ne quid nimis."

DR. FOORD CAIGER'S RETIREMENT FROM THE M.A.B.

Dr. Frederick Foord Caiger retired from the service of the Metropolitan Asylums Board on Oct. 4th after an association of 39 years with the work of the infectious hospitals. He entered the service of the Board in 1887 as an assistant medical officer, and two years later was appointed medical superintendent of the South-Western Hospital, a post he continued to hold until his retirement. In 1893 his services were utilised in the opening of the Fountain Fever Hospital, Tooting, and six years afterwards he was deputed to open and organise the administration of the Grove Fever Hospital, Tooting, an institution of over 500 beds, which was urgently needed to meet an unusually high seasonal rise of enteric fever. At the end of 1921 Dr. Caiger was appointed chief medical officer of the Board's Infectious Hospitals Service, becoming at the same time emeritus physician to St. Thomas's Hospital. In his responsible position of fever chief he was called upon to guide the policy of the Board in such important questions as the use of the Schick test, the early administration of antitoxin in diphtheria, and the provision in the hospitals for cases of measles. Dr. Caiger was the first chairman of the Scientific Advisory Committee set up by the Board, after consultation with the Medical Research Council, to advise on the extension of knowledge by research and the full and prompt application of available knowledge to fever practice. As an outcome of this advice the Board in 1925 appointed a director of research and pathological services and decided to establish two thoroughly equipped group laboratories. Dr. Caiger's retirement will mean the loss to the Metropolitan Asylums Board of a wise and tactful administrator, and to the medical staff and students of a good clinician and an attractive teacher. In many capacities he has contributed to the efficiency of the public health services of the metropolis. We are glad to learn that his help will remain available to private practitioners in the difficulties which arise in the diagnosis and treatment of fevers.

POLIOMYELITIS AND SCHOOL INFECTION.

WE referred last week to the fact that the autumn increase in the prevalence of acute poliomyelitis and acute polio-encephalitis was greater this year than usual. Poliomyelitis was separated from other forms of paralysis and defined as a clinical entity by Heine in 1840; in 1887 Medin called attention to its occurrence in epidemic form; in 1913 Flexner and Noguchi isolated an organism which was capable of producing the disease in monkeys and could be recovered from the diseased animals in pure culture. This organism was present in the pharyngeal secretion of a large proportion of sufferers from the disease, and also in the secretions of contacts and of certain patients who presented non-nervous symptoms. The disease is now regarded as a specific infection, and, though many questions in regard to its epidemiology still remain unsolved, it is established that only a fraction of those who are infected develop the paralytic form of the disease. It would appear that the great majority of the population in civilised communities is immune to the infection, or at any rate well protected against it. Children in the first year of life seem almost immune; those in the second, third, and fourth years are the chief sufferers and account for 80 per cent. of all cases; after the age of 4 the incidence declines rapidly. The fact that school infection rarely plays any noticeable part in the spread of the disease in the larger communities suggests that nearly all children in such areas are immune by the time school age is reached. It seems likely that the immunity they possess is not the result of any bodily change as they get older, but is acquired by mild infection, for in rural districts with their more limited intercourse, the disease is acquired later than in towns, the average age of incidence being somewhat higher. In a community from which poliomyelitis has been completely absent for a number of years, the younger children may have had no chance of acquiring immunity and school infection may become a danger. Wickmann, in his study of the Swedish epidemic, recorded several instances of it. The account of the smaller but more recent Tübingen epidemic of 1922 [1] contains two instances of the spread of infection through institutions in which the children had had no chance of acquiring immunity. In a village several miles from Tübingen an epidemic of "influenza" with catarrh of the upper air passages as its chief symptom fell upon the infants' school and affected so many children that the school was closed by the authorities. Then the true nature of the infection was revealed, for the teacher and one of the pupils died from paralysis. The second instance was in a home for infants comprising 14 children; all the inmates suffered from "feverish colds" and their temperature charts, all very similar, suggested an ordinary slight "influenza" epidemic. But paralysis appeared in three of them. In another German village where poliomyelitis had not been encountered for 11 years still another instance was observed [2]; a boy, who himself later suffered from paralysis, is believed to have contracted the infection from a case in the street in which he lived, and continuing to attend school while suffering from catarrhal and even paralytic symptoms he was apparently the means of bringing the infection into his school, and the disease in its paralytic form into the homes of three of his class-mates, four members of these families being involved. Oppenheim supports the statement that an increase in the prevalence of poliomyelitis during the school term and a decrease during the holidays has repeatedly been observed. If a country succeeded by hygienic measures in stamping out the infection for, say, ten years, it would appear to be rendering itself liable to the danger of an epidemic in its schools. Should this be accepted, prophylaxis would lie not so much in hygiene as in the development of a positive means of producing immunity—a method similar to those now being employed for diphtheria and scarlatina, or, as a more temporary measure, the administration of immune serum obtained from convalescents, and, if a suitable technique can be devised, from animals.

STANDARDISATION OF ARSPHENAMINES.

IN the September number of *Clinical Medicine* will be found an article on the standardisation of arsphenamines, by G. W. Raiziss, who points out that since the introduction of arsphenamine and its derivatives mercury occupies a position of secondary importance in the treatment of syphilis. These products have remarkable effects upon syphilitic symptoms and the Wassermann reaction, and their therapeutic efficiency in experimental trypanosomiasis is very marked, the injection of a dose very much below the maximum tolerated dose producing a complete disappearance of trypanosomes from the blood of rats, even where millions of the parasites had previously been present. Discussing the chemical constitution of the arsphenamine group and the reactions resulting from the administration of these compounds, Dr. Raiziss ascribes the cause of these reactions to impurities in the drug, and points out the necessity for a standard which will reduce the toxicity and retain the curative power of the substance. The United States Government assessment of the tolerated dose of arsphenamine in experimental animals is 120 mg. per kg. of body-weight, and for neoarsphenamine 240 mg. per kg. of body-

[1] Schall: Münch. med. Wochenschr., 1923, lxx., 763.
[2] Graef: Ibid., 1925, lxxii., 55.

weight, but samples allowing doses of 180 mg. of arsphenamine per kg. of body-weight and 400 mg. of neoarsphenamine per kg. have been obtained. Thus a man of average weight should be able to tolerate a dose of 24 g. of neoarsphenamine, whereas the actual dose employed is only 0·9 g., so that the margin of safety is very large. Dr. Raiziss describes some of the tests which have been performed with a view to standardisation of these products, and mentions difficulties which have been encountered. The term "chemotherapeutic index" has recently been adopted in comparing the efficiency of various drugs. This is the value obtained by dividing the maximum tolerated dose by the minimum curative dose. A point which has yet to be decided is whether the administration of these chemical compounds actually eradicates the infection or merely extinguishes the visible signs. The lymph node transfer is a valuable criterion in this connexion, but, as Dr. Raiziss points out, there are still many problems of research to be solved before a standard preparation of arsphenamine can be prepared.

BANANA FLOUR AS A FOOD FOR INFANTS.

THE use of preparations of banana in the feeding of both sick and healthy infants has extended considerably in America in recent years. Dr. A. E. Vipond, of Montreal, was among the first to draw attention to its advantages; in a paper published in 1911 he described the treatment of infantile diarrhœa by feeding with a flour obtained by drying and grinding green bananas. In a more recent communication[1] he ascribes to banana flour a far wider field of utility and claims for it a prominent place in the treatment of infantile diarrhœa and cœliac disease, and also in the artificial feeding of infants. An analysis which he gives shows that 100 parts of the flour contain only 3 of protein and 0·5 of fat, while the carbohydrate reaches nearly 80. A small portion (7 per cent.) of this is in the form of dextrose; the nature of the remainder is not stated, but its components are said to be "entirely different from the other starchy components, and readily assimilable by the youngest infant." It is claimed that the flour is rich in vitamins and that in combination with condensed milk it forms an ideal infant food which will not cause rickets. The use of bananas in cœliac disease has received support from other authors (S. V. Hass, C. G. Kerley) and has been given trial in this country. Dr. Vipond believes that sufferers from this disease do not show intolerance to this as to other forms of carbohydrate, and that they benefit from the extremely low fat-content of the mixture. He considers banana flour and condensed milk to be the best food for infants who cannot be nursed and who do not thrive on modified milk. He refers to a very large number of successful cases and has no serious failures to record. This result would appear to be an example—comparable to the successes obtained by whole-milk feeding—of the remarkable powers of adaptation possessed by the infant, as the percentage of carbohydrate present in this mixture is enormous and the protein-content relatively small.

PNEUMONIC PLAGUE.

IN a long article published recently in the *Semana Medica* Dr. J. R. Paso deals with the relation between pneumonic and bubonic plague, and the genesis of pneumonic plague as a separate entity. His actual experience, he states, is limited to the bubonic form; he quotes cases in which pneumonia supervened on bubonic infection, but recognises that this event is no more than a complication. He has made, however, a thorough study of the literature, of which he gives a long bibliography, and from this survey has come to the following conclusions. (1) Bubonic and pneumonic plague are distinct, though they are both caused by the bacillus of Yersin, and occur together. (2) Pneumonic plague is disseminated by infection of the upper air passages with droplets proceeding from those already affected; it is not an infection of the blood stream, and is transmitted by contact, not by parasites. (3) In pneumonic plague Yersin's bacillus is not the primary factor, but is a *microbe de sortie*, falling on favourable soil, prepared by the invasion of other organisms. It is, in fact, a symbiosis in which the Yersin organism ultimately plays the dominant rôle. In conjunction with his chief, Prof. Destephano, Dr. Paso puts forward the hypothesis that epidemics of pneumonic plague are due to the simultaneous onset of influenza and plague under conditions which favour the propagation of both diseases—namely, filth, overcrowding, and cold weather. A desire for warmth, he remarks, drives people to herd together in their wholly insanitary habitations. Dr. J. N. White, who reported on this subject to the Health Committee of the League of Nations, says that it is necessary to assume some symbiosis in order to explain the facts; but it is generally agreed that further investigation of new epidemics is essential before any definite conclusion can be reached.

THE PRECIPITIN TEST FOR HUMAN BLOOD.

UNTIL a few years ago there were no tests for human blood. The criminal investigator could only state that the blood on a weapon or garment was that of a mammal, and the defence that the accused had recently killed a bullock or a pig would often be impossible to refute. The growth of immunology and the discovery of the precipitin reaction have, however, added enormously to the odds against the murderer. This test was the subject of a communication to the Medico-Legal Society on Oct. 28th by Dr. John Glaister, jun., son of the medico-legal adviser to the Crown for the West of Scotland. Dr. Glaister, who has performed over 1000 tests with antiserum in Glasgow University during the last two and a half years, concludes that the precipitin test may be safely applied under nearly all conditions. It is, however, as Dr. H. H. Scott pointed out in the course of the discussion, by no means foolproof. Not only must the man who performs it have adequate and sufficiently numerous controls, but he must, as Major C. Newcomb remarked, have much experience in performing the test. G. H. F. Nuttall, who worked out the biological tests for blood some 25 years ago, found a difficulty in getting good results from old blood-stains in the tropics, but Dr. Glaister has been successful with stains 16 weeks old, even when they have been exposed to dry heat up to 200° C. Temperatures between 210–230° C. change the blood so that it will not form a solution. Steeping in cold water does not affect the test, although the albumin of the blood passes to some extent into solution, but soap in the solution under test may cause clouding and render the results unreliable. It is, Dr. Glaister said, of the first importance that the antiserum should be absolutely clear. It should be tested by putting the same number of drops as are to be used in the test into normal saline as a control. The slightest cloud justifies the rejection of the whole solution. He stigmatised the use of opalescent antiserum as a dangerous pitfall in medico-legal work, because it produces a cloud in any clear solution to which it is added. The cause of clouding in serum is not yet known, though Dr. Scott pointed out that it might be due to killing the animal too soon after a meal, when there was still a large amount of fat in its blood stream. He suggested that the increased opalescence which appears when the serum is added to any other solution may be due to a colloid change, the fat becoming more finely emulsified. The error which results from the use of opalescent antiserum should be suspected even if it has been allowed to enter into an actual experiment, because the haze produced is distributed evenly throughout the tube, whereas the haze of a positive reaction appears only in the lower third of the tube. The reaction from an

[1] American Medicine. New series, July, 1926, vol. xxi., No. 7.

old stain is complicated by an upper zone of cloudiness due to bacterial invasion. Dr. Glaister confirmed Nuttall's observation that the presence of a second blood in the stain does not compromise the reaction, but found, nevertheless, that it reduces its strength. The absolute specificity of the precipitin test has been accepted by many expert pathologists, but Dr. Glaister found himself compelled to support the observations of Kister and Wolff, who showed that antihorse serum might give a positive reaction with human serum in an acid medium. He found that acid media interfered with the reaction and that alkaline media prevented it. This is probably due to the interaction between the blood-serum and the acid or alkali in the fluid under test. Dr. Scott agreed that it might be impossible to prove that human blood was not horse blood, but he has not found the converse to be true. The precipitin test is known to be unreliable when the stain is on leather, possibly as a result of some part of the tanning process. Dr. Scott had also found that stains on wall-paper were unsuitable for this test, and that it was necessary to bubble CO_2 through such materials as mortar, lime, and plaster in order to get rid of the calcium carbonate before testing. Dr. Glaister's exhaustive experiments with different kinds of wood, rough and polished, and with many kinds of material, showed, however, that the precipitin reaction remained unaltered, even after 14½ years in one woollen stuff. Dr. Glaister found that the foam test was of no value for indicating the strength of the blood serum present. He therefore introduced the "shaking test," which he found to give some guide to the strength. Both of these tests are of qualitative rather than quantitative value, and would be compromised by the presence of soap or anything else which produces foam. The colour-test also could be affected by many factors, such as CO_2, the age of the stain, the amount of the hæmoglobin, and the species of the animal which supplied the blood. Dr. Glaister has introduced certain refinements of technique, such as his microscopic cover-glass troughs, framed in black wax, which will be of interest to those who work with this reaction, and his careful survey of the field will strengthen belief in the medico-legal value of this test.

THE ROYAL COMMISSION ON MENTAL DISORDER.

IT is now just over two years since the Royal Commission on Lunacy and Mental Disorder held its first session. Public disquiet had been aroused by various publications and legal proceedings with their alleged "revelations," and the Commission was appointed under the following wide terms of reference:—

1. To inquire into the existing law and administrative machinery as regards England and Wales in connexion with the certification, detention, and care of persons of unsound mind, or alleged to be of unsound mind.

2. To consider the extent to which provision is or should be made for the treatment without certification of persons suffering from mental disorder, and to make recommendations.

The Commission, with this widespread popular anxiety in view, made it their special charge to hear patiently and consider carefully the evidence of all kinds of witnesses, and spent many months in a conscientious endeavour to establish a firm basis for their subsequent recommendations. The minutes of evidence, which have recently been published [1] and which occupy three large foolscap volumes, are the unadorned transcription of the shorthand notes and have neither preface nor summary. This mass of evidence includes that of medical associations, individual medical man, medical officers of mental hospitals, nurses, commissioners in lunacy, legal authorities, and ex-patients; 21,659 questions were put and answered. The appendix contains memoranda prepared by the British Medical and Medico-Psychological Associations, and a careful and complete index of the whole. These documents, together with the report of the Commission,[2] make very interesting reading for those who are concerned in mental hospital administration, and constitute valuable reference books for the library shelves.

IMAGINARY ANNALS.

THOUGH the Royal Society of Medicine can claim ancient lineage, its roll of Fellows is necessarily confined to somewhat recent times, and there is ample scope for the kind of reconstructive history with which Sir D'Arcy Power entertained the Section of Comparative Medicine in his presidential address on Oct. 27th. Hippocrates, he thought, would have been chosen first President of the Section if it had existed in his day, for he realised that the diseases of men and of animals were closely allied. A candidate for honorary membership would have been a man of colour, Mago, the Carthaginian, who was termed the father of agriculture, and wrote 28 volumes on all branches of the subject. Xenophon, too, would have been a member, as he had a real interest in horses, and was skilful in their management, summing up his views in the words "keep the hoofs hard and the mouth tender." Vegetius would also have belonged to their body; far in advance of his time, he ridiculed the prevalent opinion that disease was evidence of Divine wrath; whilst Pliny would certainly have joined the Section, for, like the Master of Balliol, he took all knowledge for his province, and his "Natural History" was an eminently readable book. Next to Pliny, said Sir D'Arcy Power, Cornelius Celsus must have been included, though it was not clear whether he was a veterinarian or a practising doctor. Coming nearer to our own time, such a Section would have admitted to membership Conrad Gesner, who was designated the German Pliny, and who awakened science from its long sleep. He practised for many years at Zürich, and when, at 49 years of age, he died of the plague, he had written 49 volumes dealing with the habits and diseases of animals. Gervase Markham and Robert Lovell would likewise have found recognition, the latter for his complete history of animals and minerals—notwithstanding that Major-General Sir Frederick Smith wrote of him as a soldier, a scholar, a gentleman of fortune, a minor poet, a literary hack, and a social parasite. Had such a combination as the Section been formed in his lifetime, John Hunter would have been elected its President; Astley Cooper, Cline, and Simmons would have been associated with him, and Edward Jenner would have been persuaded to read a paper. Passing to recent times, Sir D'Arcy Power spoke of Charles Sainbel, William K. Parker, and Thomas Henry Huxley. In proposing a vote of thanks, Sir W. Arbuthnot Lane added to Sir D'Arcy Power's list the name of Æsculapius, which, he said, should certainly have been included; and Prof. F. Hobday, seconding, congratulated the Section on its President's erudition. We hope that the Royal Society of Medicine will invoke his aid if they should follow the example of some American societies and elect to posthumous Fellowships distinguished physicians whom accident of birth has deprived of this recognition in their lifetime.

OFFICE INTERNATIONAL D'HYGIÈNE PUBLIQUE.

THE final day of the October session of the Permanent Committee of the Office International d'Hygiène Publique, just concluded in Paris, was saddened by the announcement of the death of Mr. J. de Cazotte, the director of that organisation from its establishment in 1907 until his resignation, on grounds of ill-health and advanced age, after the International Sanitary Conference in June last.

[2] Cmd. 2700. H.M. Stationery Office. 1926. 3s. 6d.

While the value of his services to public health during this long term of office was always well known to his own international committee and in official circles, it was little realised, outside them, how much Mr. de Cazotte had contributed to the organisation and development of that mutual coöperation between the public health services of the world which is now accepted on all sides as a necessary and normal part of official international relations. A French diplomat, with no pretentions to medical knowledge or training, Mr. de Cazotte had acquired an experience and sagacity in all matters relating to international agreements on health questions, notably regarding the successive conferences and conventions which regulate quarantine and port sanitary work; these proved invaluable wherever such agreements had to be prepared and revised. Keeping always meticulously within the limits of his official duties, he had come to possess a sure instinct for discriminating between those matters which were officially appropriate and necessary for the effective functioning of the organisation he directed, and those which might infringe the cardinal statute that the Office International d'Hygiène Publique must not in any way interfere with matters of internal administration in any country. He had the satisfaction of seeing the number of countries which adhere to the agreement of 1907 steadily increase until now its committee includes technical delegates appointed by almost every government of the world; his untiring industry was largely responsible for the high standard which the monthly *Bulletin* of the *Office International d'Hygiène Publique* has always maintained, while his last official appearance was on the occasion of the completion of the International Sanitary Convention of 1926, and its signature by the representatives of nearly 70 governments. He has been succeeded in the office of director, as was fitting, by Dr. Pottevin, his medical collaborator during the whole of this period, who has long occupied a distinguished place in the domains of hygiene and in the French Senate, of which he is a member. The new director, in developing the wider policy and outlook which the Office International has assumed in consequence of the recent agreements and of its function as the Advisory Health Council of the League of Nations, undertakes a difficult task, but one for which the high reputation already possessed by the International Office will be an invaluable asset.

THE CAUSATION OF PHLYCTENULES.

PHLYCTENULES are among the most common affections of children met with in the ophthalmic out-patient department, and though, in the majority of cases, eminently amenable to treatment, are in a minority obstinately recurrent, leaving more or less permanent scars on the cornea which are responsible for a notable degree, not of blindness, but of impaired vision in the general population. The ætiology of the disease has long been disputed. Many have held that there is a real connexion between phlyctenules and tubercle, though exactly what no one has offered to explain. Tubercle bacilli have never been found in phlyctenules and to say that the affected children are, if not tuberculous, candidates for tuberculosis, does not carry us very far. The same might be said of any poorly nourished children. It is, no doubt, a fact that attention to the diet and nutrition of the child is an important element in treatment, but that does not explain the typical phenomena of the disease. Mr. Bishop Harman has put forward a theory connecting it with decay of the milk-teeth and suggests that the lesion is a herpetiform eruption caused by peripheral irritation of collateral branches of the second division of the fifth cranial nerve in ill-nourished children. So far as we are aware this theory has not received any marked degree of general support and it is obviously inapplicable to many cases that occur. Some new light on the subject is to be gathered from a contribution to a *Festschrift* by the Swedish ophthalmologist, Hugo Laurell, dealing with the pathogenesis of scrofulosis.[1] Put shortly, his theory is that the bites of human parasites may introduce into the host foreign proteids which give rise to a condition of anaphylaxis in which any external application of the same or even of kindred proteids causes a local reaction of which the phlyctenules are a manifestation. The parasites with which children subject to phlyctenules are most commonly infested are first worms, and especially oxyuris, secondly pediculi. Both cause local irritation and scratching, and the conveyance of the offending substance by means of the fingers to the conjunctiva must frequently take place. In dealing with affections so common among the children of the poor, it is obviously difficult to get any statistical proof of the connexion between these conditions that is not free from objection. At the same time a perusal of Dr. Laurell's article does leave the impression that there probably is some truth in this theory. At any rate, he has pointed the way to a direction in which research would appear to be hopeful. It is established that phlyctenules can be experimentally produced by the local instillation of tuberculin or of dead tubercle bacilli in animals already infected with tuberculosis. Funaishi has found that in non-tuberculous animals injected with non-tuberculous bacteria (staphylococci, &c.), instillation of the proteids of these bacteria has a like effect. It is, therefore, clear that tuberculosis is no necessary antecedent to phlyctenular disease. Laurell's theory is that the subjects of phlyctenules, having been inoculated with the proteids of parasites, usually oxyuris or pediculi, reinfect their eyes by means of their fingers which carry the noxious material from the infected spots to the conjunctiva. If this is a fact one would expect to find phlyctenules more often at the inner margin of the cornea than at the outer. Mr. Harman found that 70 per cent. were situated in the outer and upper quadrant, the spot to which the orbital branch of the second division of the fifth nerve sends its terminal twig. This is a point which might be reinvestigated.

WE regret to announce that Francis Mitchell Caird, emeritus professor of clinical surgery in the University of Edinburgh, died on Nov. 2nd.

THE Bradshaw Lecture of the Royal College of Surgeons of England will be delivered in the theatre of the College by Prof. E. W. Hey Groves next Thursday, Nov. 11th, at 5 P.M., the subject being Reconstructive Surgery of the Hip-joint. Students and others, who are not Fellows or Members of the College, will be admitted on presenting their cards.

The Services.

ROYAL ARMY MEDICAL CORPS.

Col. H. B. Fawcus to be Maj.-Gen.

The undermentioned Capts. to be Majs.: H. S. Milne (Prov.), Q. V. B. Wallace, F. C. Chandler, and T. F. Kennedy.

Capt. A. P. Draper, is secd. for serv. under the Colonial Office.

TERRITORIAL ARMY.

Capt. J. H. Cobb to be Maj.

ROYAL AIR FORCE.

H. Penman is granted a short service commission as a Flying Officer for three years on the Active List.

Flying Officer N. I. Smith ceases to be seconded to the King's Cross Hospital, Dundee.

Flight Lt. T. M. Walker is transferred to the Reserve, Class D.2.

INDIAN MEDICAL SERVICES.

Temp. Lts. Girdhari Lal Puri and Daya Ram Malhotra to be Temp. Capts.

Tharmale Govinda Raghava Panikkar to be Temp. Lt.

Modern Technique in Treatment.

A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions.

CXCVI.—THE TREATMENT OF INFECTION OF THE NASAL ACCESSORY SINUSES.

FOR some years there seems to have been an increasing number of cases of acute sinusitis during the period autumn to spring, after which only sporadic cases occur.

Symptomatology.

In a typical case the patient gives the history of a severe cold. During the first week aching and throbbing of the cheeks and at the back of the eyes, nasal obstruction, and brow-ache with mucoid secretion occur. The condition may then subside, or, if neglected, the pain may become more intense and more localised, usually over one cheek with tenderness to pressure in the region of the inner canthus or in the supraorbital region, which becomes definitely painful and tender. With the pain there is nasal obstruction, followed by muco-purulent or purulent discharge on the affected side. In other cases there may be most pain in the temporal region, or frontal and vertical headache with tenderness in the occipital region and stiffness in the back of the neck. Or a sharp attack of influenza with nasal symptoms may leave a unilateral discharge from the nose or a persistent post-nasal catarrh. Later the only symptoms may be a bad smell in the nose. Very severe or fulminating cases may show signs of acute septic absorption or even septicæmia, the patient becoming rapidly worse, with a swinging temperature, and later drowsy and toxic. Meningitis, thrombosis of the frontal vein, or osteomyelitis with spreading œdema of the brain may follow, especially when the frontal sinus is involved. In most of these severe complicated cases there has been neglect of a bad cold, an unrecognised acute sinusitis, or a chronic inflammation which has suddenly lit up.

Differential Diagnosis of the Sinus Affected.

Roughly speaking, unilateral brow-ache suggests frontal sinusitis; pain deep to the eye and especially at the inner canthus suggests ethmoiditis. Face-ache suggests maxillary antritis; occipital and vertical pain, sphenoidal sinusitis. Similarly, tenderness over these regions may help to localise the lesion. There are, however, several traps here; for instance, the pain of acute maxillary antritis may be localised to the temporal or supraorbital regions on the affected side. The headache may be occipital, vertical, or frontal in cases of ethmoiditis without involvement of the sphenoidal sinus. Routine examination should, therefore, always be made.

Anterior Rhinoscopy.—On examining the anterior nares with a nasal speculum, swelling and congestion of the middle and inferior turbinals will be the only sign of sinusitis unless the sinus has commenced to drain. Later mucus or muco-pus may issue from under the anterior end of the middle turbinal, when the antrum or frontal sinus are affected and still later a streak of definite pus will be seen.

Posterior Rhinoscopy.—With the post-nasal mirror a streak of pus may be seen coming down from under the posterior end of the middle turbinal, since the antrum often drains backwards. If the posterior ethmoidal cells or the sphenoidal sinus are involved the streak of pus will issue high up in the post-nasal space above the posterior end of the middle turbinal.

Transillumination is most useful in antritis. Absence of a crescent under one eye is diagnostic of past or present antritis. A clear crescent under each eye negatives an acute or chronic affection. Transillumination of the frontal sinus is inconclusive, the diagnosis being more easily made by the presence of tenderness, swelling, or reddening over the area combined with the results of anterior rhinoscopy and radiographic examination.

It is noteworthy that—

(1) In some persons, especially men with thick and heavy upper jaws, a crescent under the eyes cannot be seen.

(2) An antrum which has previously been operated on may remain dark on transillumination.

(3) Where a large antral polypus occupies the antral cavity the latter will be hyperclear to transillumination but dark to a radiogram.

Radiographic examination is most valuable since, if all the sinuses are clear, sinusitis can be definitely excluded.

In certain individuals a severe cold always means involvement of the antra so that the latter, though transparent between attacks, become temporarily opaque to transillumination and radiogram. In others a series of acute attacks has produced a chronic sinusitis. Again, a patient may have a chronic antritis shown only by post-nasal catarrh in the mornings, or an inflammation of the frontal sinus, of which the only signs are periodic attacks of frontal neuralgia and some nasal catarrh. If such patients contract an acute nasal infection, the already degenerated and polypoid mucous membrane of the cavity previously affected cannot easily recover, and operation on an acute on chronic antritis or ethmoiditis is not unattended by danger; again, in frontal cases, osteomyelitis of the frontal bone may supervene, the prognosis being very bad.

It may be taken almost as an axiom that a patient ill with a heavy head cold and with unilateral pain in the face, temple, or brow has an extension of the inflammation of the mucous membrane of the nasal cavities into one or other nasal accessory sinuses. Probably in any severe nasal infection, the mucous membrane of the sinuses is involved, since they are all continuous in their mucous lining and communicate with the nose. It does not follow because the mucous membrane of a sinus shares in the congestion and hypersecretion of the nasal mucous membrane that surgery is indicated; in fact, in most cases, especially when the maxillary antra and ethmoidal cells are involved, medical treatment will be effective, the inflammation will resolve, and the cavity return to the normal. The exception to this is (1) when the natural opening of the sinus becomes so blocked that the cavity cannot drain, retained muco-purulent secretion becomes purulent, and the lining membrane of the cavity becomes so damaged that it cannot recover without artificial drainage; (2) when signs of general toxæmia or septicæmia are urgent indications for the drainage of the septic focus; (3) when the acute condition does not clear up but becomes subacute or chronic.

The maxillary antrum may be infected from a tooth, usually the first or second molar or the second bicuspid; the canine rarely or never infects the cavity. The infection occurs from infection of the tooth socket or from an apical root abscess. The abscess may burst directly through the antral mucous membrane or the infection may extend through the membrane without its rupture. It often follows or is ascribed to the removal of a tooth and this is not surprising, since a tooth may be removed because of an apical abscess, when infection of the antrum has already taken place, or the removal may leave a fistula into the cavity. Not infrequently there is no bony covering between the tooth root and the cavity, the apex being covered only by mucous membrane, which may be torn during extraction, leaving a communication between the septic alveolus and the antrum.

If an acute antritis has a dental origin the proper procedure is to remove the tooth. If a communication with the antrum is established by this means it is justifiable to wash out the cavity through the fistula once or twice, but the fistula should then be allowed to close, routine treatment of the acute antritis being carried out. The patient should not be encouraged to force lotion from the mouth into the antrum. The archaic treatment of acute antritis by removing a sound tooth and then inserting a screw plug or tube so that the fistula could be kept open and the antrum washed out through it, is now happily a thing of the past. Such a procedure allows of continued reinfection from the mouth, and frequently converts an acute antritis, which would probably clear up, into a chronic condition.

General and Local Measures.

The patient should be put to bed, the head being propped with several pillows. The bowels should be kept well open and ordinary medicinal treatment given if there is pyrexia. A steam inhalation should be given four-hourly, the steam being inhaled through the nose and exhaled through the mouth.

The simplest method is to use a quart jug half full of boiling water; a bath towel is placed over the head and jug and the patient inhales as long as the steam rises, usually about five minutes. As a basis Friar's balsam is a useful inhalant,

strength ʒ i. ad. O i. boiling water. To this may be added a little menthol or pinol.

In cases of antral infection, after the inhalation the patient should "posture"—i.e., lie with the head hanging over the side of the bed on the opposite side to the sinusitis—and then sit up, close the nostril on the sound side, and try gently to blow out the secretion from the other. The nose should not be blown with a handkerchief, nor should it be blown violently, especially if the turbinals are congested and there is nasal obstruction, for pus may be blown up the Eustachian tube and infect the ear.

In between the four-hourly steam inhalations the patient should use a fine nasal nebuliser containing the following or similar prescription:—

Menthol gr. xv., cocaine gr. iv., glycerine ʒ iii.
Tr. benzoin simplex ad. ʒ i.

If the vestibule of the nose becomes dry or cracked sterilised vaseline or cold cream may be applied.

Treatment should be continued until the secretion drains away and there are no pressure pains in face or forehead. If the secretion does not drain well, owing to obstruction of the osteum maxillare or infundibulum, relief is often obtained by the following procedure:—

A pledget of cotton-wool is soaked in 10 per cent. cocaine and then squeezed so that it is only damp. It is then placed between the middle turbinal and the septum, so as to shrink the latter. This pledget is removed and a second one placed under the middle turbinal so as to shrink up and open the outlet from the antrum, frontal sinus, and ethmoidal cells.

After cocainisation, steam inhalation and, in the case of antral infection, "posturing" should be employed. If the antrum does not drain despite these methods, puncture through the inferior meatus, together with lavage, may be used. As a solution for this purpose an antiseptic and alkaline lotion, such as glyc. thymol co., B.P.C., should be used to which has been added 1 drachm of tr. iodi. to one pint of the lotion. Placing a hot box (i.e., one arranged with electric bulbs on the principle of the ordinary heat bath) over the head may promote draining and relieve pain. Artificial sunlight has also given good results. These measures may be combined with autogenous vaccines, except in the acute stage, when a serum is preferable, together with adequate drainage.

Cocainisation, followed by steam inhalations, should be employed in all cases of acute sinusitis. Posturing is particularly useful in the case of the antrum. It must be remembered that in these acute cases there is often an acute polysinusitis—that is to say, the anterior ethmoidal cells, frontal sinus, and antrum may be also involved.

Precautions in Operation.

In acute cases where operation is indicated it should be limited to free drainage of the affected sinuses, with as little traumatism or disturbance to the tissues as possible. To open up new surfaces may allow a fresh inlet to infection and produce septicæmia.

In acute antritis the cavity should be opened for drainage if necessary, but the Caldwell-Luc operation should not be performed. In frontal sinusitis the anterior end of the middle turbinal should be removed, the infundibulum enlarged, and the sinus washed out. If this is not sufficient it must be opened and drained in the supra-orbital region. In ethmoidal sinusitis there may be rapid necrosis and disorganisation of the cells; safety again lies in free drainage, the necrosed tissue being rapidly but gently curetted.

It is rare to find the sphenoidal sinus attacked in acute cases, but if it is, the ethmoid will probably be involved too, when access should be obtained by removal of a portion of the middle turbinal, the opening of the sinus enlarged, and the cavity washed out.

Conclusion.

In genuine acute attacks of sinusitis obtain drainage by medical means if possible; if not, simple surgical drainage should not be delayed. In chronic cases a radical operation should be performed during a period of quiescence, free drainage being given and any hopelessly degenerated mucous membrane removed.

NOTES ON THE MOTOR SHOW AT OLYMPIA.

THIS year the Motor Show was distinguished by lower prices and better cars. Four-wheel brakes, low-pressure tyres, shock-absorbers, and the cellulose finish are general. The standard of value is so high and such pains are taken over equipment and finish, especially of the covered cars, that it is not a little disappointing to find the same minor faults of design perpetuated by makers of the greatest experience in cars which are otherwise first class. The simultaneous demand for four-door saloons and right-hand control has resulted on car after car in the anomaly of a driver's door by which no driver, however agile, could possibly leave the car. The doctor should be extremely careful to see that the car he chooses has a driving position in which he is certain of remaining comfortable all day and in which he can reach the controls without leaning forward. Some of the best-known models leave very much to be desired here. On one, in particular, the right-hand gear-lever is so arranged that the handle would be inaccessible if the driver had a stiff knee or were wearing a skirt. Several hand-brake levers are so close to the body-work that the driver cannot put his hand round them. These faults outweigh any number of silk window-blinds, antique leather cushions, and electric cigar-lighters.

The 1926 show will be remembered by two features—the "small sixes" and the £100 cars.

£100 Cars.

There were two £100 cars at Olympia and a third, the Lafitte, at the Paris Salon. The last is driven by a three-cylinder radial air-cooled engine, and is hardly a car for the doctor. Of the two British attempts to market a car at this figure one is the Waverley, made by the well-known makers of that name, and the other is the Gillett, made by the Ensign Motor Co. The Waverley is very low and not very attractive in appearance; its engine is an opposed water-cooled twin resembling that of the Jowett and placed behind the back wheels, one of which it drives through a G.W.K.-type friction gear. The car is wound up at the tail.

The Gillett has a self-starter, a speedometer, balloon tyres, and all reasonable equipment, and follows orthodox car practice throughout. It has ample leg-room for two and a boot for luggage or two occasional passengers; its overhead-valve engine will propel it at 30 m.p.h. on middle gear and 50 on top; its steering-lock is ample and its four-wheel brakes as effective as those of a large car. It will not, however, be ready before April. It deserves to succeed, and may yet solve the car problem for many indigent practitioners.

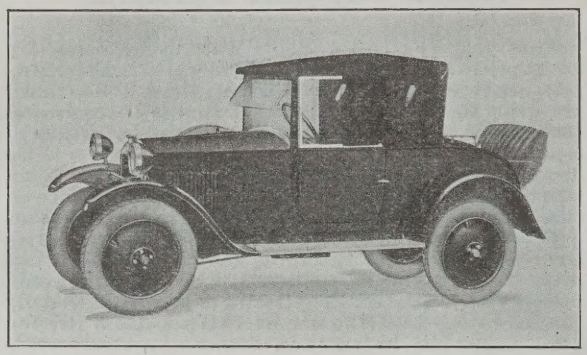
Covered Cars for the £200 Purse.

The 7/12 Peugeot cabriolet (Fig. 1) is one of a type of small coupés common in France, but unknown (with the doubtful exception of the Austin 7) in England. Its close-fitting hood and sliding windows give that positive protection that no all-weather equipment can. It is neat-looking, and would suit a modest town practitioner very well, but its low gear ratio would make it tiresome on a long country round. It has a single dickey with a smart luggage-grid on the trap-door, and its price, £165, includes all the usual modern equipment and a cellulose finish.

The 7 h.p. Jowett four-door saloon always seems an impossibly huge body for so tiny a frame, but the car appears to do the work. At £185 it is a good bargain. The rear passengers have a surprising amount of leg-room, but the roof is a little low. Its chief advantages is its £7 tax and its low running costs. Another £10, however, will secure the Morris-Cowley saloon at £195, and many doctors will consider the extra annual cost well repaid by the greater reserve of power latent

in this 1560 c.c. engine. Morris Motors have stolen a march on their rivals by producing a full saloon at less than £200, and a well-finished and well-made one at that.

FIG. 1.

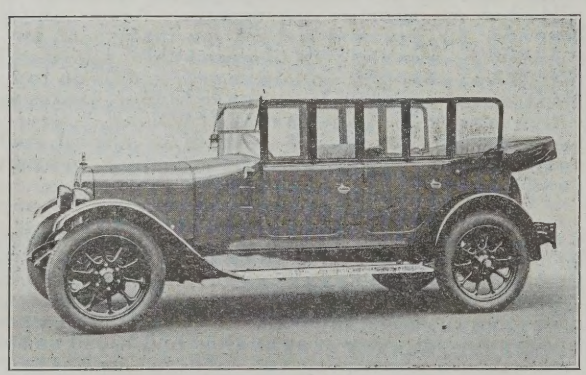


7/12 Peugeot cabriolet.

Up to £300.

There is always a large group of practitioners who, having run a cheaper car for some years, feel that at last they can afford a little more. It is these who really get the fun out of a show, as they have a field of choice at least five times as wide as that of their friends who only wish to spend £200, and they know that even if they were spending £1000 they could only get a bigger car, not one better made or more luxuriously fitted and probably not even a faster one. The first competitors for their notice are, of course, Morris-Oxford, Clyno, and Citroën, with saloons at £265, £250, and £240 respectively. The coachwork of the Citroën is not so well finished, and for most people the choice will remain between the Morris-Oxford 14/28 (which is really only a 12) and the Clyno 12/28 (the engine of which is smaller even than that of the Morris-Cowley). The equipment of both is prodigal and the choice is really between 300 c.c. of engine capacity and £15. Coupés are a shade cheaper than saloons. Those who are prepared to pay more than £250 for a really fine open car should consider the Austin Clifton tourer at £275. In Fig. 2 it

FIG. 2.



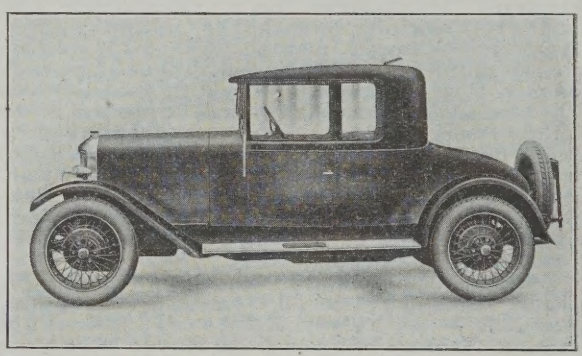
Austin Twelve "Clifton" Tourer.

is shown with screens up. A compromise in build is the Lea-Francis 12 h.p. semi-coupé at £295. "Semi" implies a coupé hood, but side-screens instead of railway-carriage windows; the protection is ample. This car has four speeds and an overhead-valve engine, and is thoroughly good in every way. The Rover 9/20 has been immensely improved by having semi-elliptic springs fitted in front to take the strain of the front-wheel braking. The engine has an exceptional performance for its size. For the general practitioner the detachable head coupé model at £235 is almost ideal, for it is a closed car which can be changed into an open two-seater in a few minutes by taking off the head and substituting an ordinary hood. The permanent coach-built coupé costs £285. The small Fiat (tax £8) is one of the most interesting of this year's cars. Its engine is just under a litre in size, but is highly efficient. It was originally called a 7, but is now advertised as 9 to do justice to its roominess and power. It has exceptionally good body-work, and the coupé at £265 is likely to attract many doctors away from the British market. The Bean 12 two-seater at £275 and "short 14" two-seater at £295 both have four speeds and roomy bodies and can be thoroughly recommended.

Up to £400.

One of the most attractive doctors' cars in the show, if not the most attractive, was the 12/40 Riley Wentworth coupé (Fig. 3). Its outstanding feature is that behind the driving seats is a space large enough for two people's luggage or two occasional seats. Two more passengers can ride in the dickey. The driving position is admirable, and either central or right-hand control can be supplied. The rear window is very large and there is an efficient roof-ventilator. The price is £385 only. The Windsor 10/15 is not so well known as most English cars, for the reason that it is made in comparatively small quantities, but it bears the marks of very careful workmanship and is superior in finish

FIG. 3.



12/40 Riley Wentworth coupé.

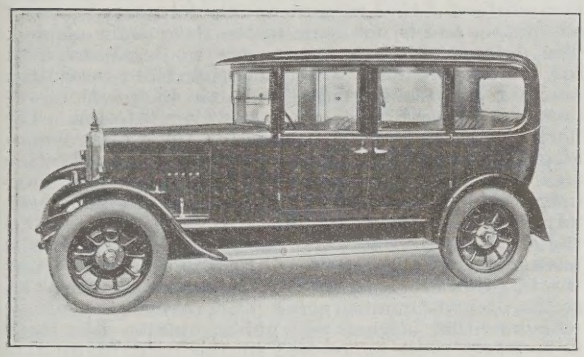
to many much more expensive makes. The coupé and saloon are both sold at £395 and there is no better value in the show. The driving position is good. Another splendid car of this kind is the Galloway 12/30, a small Arrol-Johnston. The fixed-head coupé at £375 has, besides its comfortable driving position, several individual features, such as room for a bag behind the driving seats and a wind-screen with small inclined side-panels, a construction which completely eliminates the "blind-spot" that spoils so many covered cars. It is impossible to leave this class without mentioning the Austin 12 Windsor saloon at £350. Besides being one of the handsomest and most dignified cars of its size in the show, it is equipped on a scale which must cut the makers' profit down almost to nothing. The Standard Motor Co. have once again produced a six-cylinder car, and, good as their pre-war one was, the newcomer will certainly be much better. It has an exceptionally graceful straight line from the shoulder of the radiator to the scuttle, and thence to the rear. The "Corley" coupé is finished in fawn, crimson, or blue cellulose, with leather to match, at £385, and a similar 14 h.p. 4-cylinder coupé costs £315.

Over £400.

Generally speaking, money expended in excess of this sum will buy more power but not higher quality, but there are a few cars in which a high first cost really represents unusual accuracy in mating parts and cutting gears. One of these is the Alvis, an 11·9

which is far and away better than everything of its size but the Aston-Martin. The 2/3-seater with the semi-coupé head at £485 is the model perhaps most likely to appeal to medical men, while the saloon (Fig. 4) is a beautiful car. The equipment is everything that could be desired. The Wolseley Company are showing a new 16/45 six-cylinder model of two litres capacity which many experts say is the best car they have ever built. Its engine is vibrationless up to 60 m.p.h., and the seating arrangements are

FIG. 4.



12/50 Alvis saloon.

very roomy. The sides are high and the side-curtains make a complete weatherproof fit. At £450 for the two- or four-seater it is a remarkable bargain. The 18 Armstrong Siddeley, which has now been a favourite for some years, represents a successful attempt to make an English medium-powered six-cylinder car at the price of an American one, but much better. The "Harlech" coupé at £540 accommodates three people abreast, one definite advantage of the larger car, and provides locker space behind the adjustable seat-back and a double dickey. The Ansaldo is an Italian car which has gained considerable popularity in this country. Four models are made, including a two-litre six-cylinder.

More Expensive Cars.

In the frankly expensive class there was a 14/40 Vauxhall on Mann Egerton's stand which would do credit to any specialist. The body is a fixed "saloon coupé" corresponding rather in arrangement to the "occasional four" of the humbler makes, with two tip-up seats behind the main bank and a large open space for luggage, also a double dickey. The finish is dark green cellulose, with upholstery to match.

American Cars.

The Overland Whippet is American only in type, for it is manufactured in Canada and designed almost like an English two-litre car. The five-seater touring car at £198 and the saloon and fixed-head three-seater coupé at £234 each, fully equipped, are excellent value. The coupé has an anti-glare visor of green glass. Studebakers have put on the market what is really rather a wonderful car, the Erskine 16/40 h.p. six-cylinder. The capacity is about two litres and a third. The makers claim to have designed and built a car to an "ideal" specification embodying the composite demands of motorists of all countries. The unsightly detachable rims and the somewhat meretricious appearance of even the good American car are refreshingly absent, and the general appearance is very good indeed. The price is absurdly small—£295 for a really well-built saloon.

The Chrysler is a most satisfactory American car of the better class. Three models are made, all six-cylinders, the "60," the "70," and the "80." The figures relate loosely to brake horse-power and maximum speed. The "60" touring-car costs £380 and the coupé £425. The R.A.C. rating is 21.6 h.p.

Accessories.

Judging by the equipment now regarded as indispensable to the modern car and included in its price, one might be excused for asking how the retail accessory dealer manages to make a living. The galleries did not indicate, however, that his prosperity is seriously impaired. There are still some useful accessories that are not standard equipment. For instance, the student of the catalogues might search through many before he found mention of a fire-extinguisher, and yet a chance petrol fire would reduce the glory of the most magnificent saloon to wreckage in 30 seconds. A Pyrene is a complete fire insurance policy in itself and costs £3 3*s*. No car should be without it. Another quite indispensable accessory that is practically never given with the car is a Schrader tyre gauge, price 7*s*. 4*d*.

The jacks and pumps supplied with many cars are not all they might be, and the owner-driver will often prefer to make his own choice. For light cars the "Atlantic" lazy-tongs jack is pleasant to work with, as it lifts very quickly, and the "Quiftlick" ratchet jack is a joy. The doctor should prefer a jack that lifts with an up-and-down movement before one that screws. Hydraulic jacks are expensive but pleasant; Ross Courtneys' "Little Jackie" at 50*s*. is a good example. Foot-pumps can be used with less strain than hand-pumps. The Dunlop at £2 2*s*. is satisfactory; one of the best is the "Mac-Pneu," which has two cylinders and two pedals and is worked by "marking time" with both feet. Lodge this year showed a still larger range of sparking plugs, including models especially designed for Morris, Ford, and Daimler, a priming plug through which petrol may be injected in cold weather, and a miniature plug.

MEDICINE AND THE LAW.

Successful Claim for Fees.

"THE moderation of most doctors with regard to fees always surprises me," observed Mr. Justice Roche last week during the hearing of a surgeon's claim in respect of professional services. The plaintiff, Mr. E. J. Deck, of 55, Welbeck-street, was suing Captain A. C. G. Smith, of the Royal Automobile Club, for £65, representing treatment over many months. Sir Alfred Fripp, a witness for the plaintiff, approved the treatment administered and stated that he considered the fees charged were very reasonable. It was at this point that the learned judge interposed the observation already quoted. The case contained no point of law. There was no question that the services had been rendered. Captain Smith, suffering from swellings in the neck, consulted Mr. Deck who administered treatment by ultra-violet rays. The defendant also attended a dentist who advised the extraction of his teeth, the dentist stating in court that his fees also remained unpaid. Eight months after his first consultation with Mr. Deck Captain Smith went to another surgeon and was operated upon. He took the view that his previous treatment had been wrong and, in answer to the plaintiff's claim for his fees, he set up the defence that the plaintiff had been negligent in the diagnosis and treatment of the case; he also counter-claimed for damages on the ground of this alleged negligence. The jury found for the plaintiff and judgment was given for Mr. Deck for the full sum claimed with costs on the High Court scale, as well as on the counter-claim.

Woman Juror's Illness.

Since June 1st, when Section 15 of the Criminal Justice Act of 1925 came into force, the death or illness of a juryman in a criminal trial is no longer a cause for breaking off the hearing and starting afresh with a new jury. At Chester Assizes last week a woman juror showed signs of faintness during a manslaughter trial. The judge deemed her incapable of continuing to act, and the trial proceeded without

her. This can be done under the Act provided that assent is given in writing by or on behalf of both the prosecution and the accused, and provided that the number of remaining jurors does not fall below ten. The Sex Disqualification Act, which first made women competent and liable for jury service, allowed a woman to apply to be exempted from serving in respect of any case "by reason of the nature of the evidence to be given or of the issues to be tried." Exemption is freely granted under this provision. The Act also allowed women to be excused attendance as jurors if they were "for medical reasons unfit to attend." This concession is amplified by the various rules governing procedure in criminal cases, in the High Court and in the County Court. The summons to a woman juror must, under these three sets of rules, notify her that she may apply for exemption from attendance "on account of pregnancy or other feminine condition or ailment," if the application is made within a fixed time-limit. The rules provide that the application may be substantiated by medical certificate or otherwise.

What is "Wine."

Mention was made last week of the conviction of a Brighton chemist for selling "Wincarnis with quinine" without being the holder of a justices' licence to retail intoxicating liquor. The magistrates had decided that the liquid was wine and the High Court declined to interfere. The law does not attempt to define wine on any standardised basis of chemical analysis. Acts of Parliament, of course, look upon intoxicating liquor from many different points of view. Thus an Inland Revenue Act of 1880 says "wine" includes sweets, and "sweets" include "made wines, mead, and metheglin." For the purpose of the liquor licences duties under a Finance Act of 1910, "wine" means wine imported into Great Britain and Ireland, while a Finance Act of 1920 mentions that "wine" includes lees of wine. These scattered interpretations bring us no nearer to knowing what constitutes wine for the general purposes of the law. The Refreshment Houses Act of 1860 essays a rule-of-thumb definition of spirits—"any fermented liquor containing a greater proportion than 40 per centum of proof spirit"—and in the same section it is laid down that liquor sold or offered for sale "as being foreign wine or under the name by which any foreign wine is usually designated or sold" shall be deemed foreign wine as against the seller. Under this latter provision a person who was licensed only to sell sweets and who, being asked for a bottle of the best sherry, supplied a bottle labelled "Best pale sherry, British," was held properly convicted of selling foreign wine. Sherry, evidently, means sherry from a foreign country where recognised sherry is produced. Parliament has given a similarly restricted meaning to port and madeira. The Anglo-Portuguese Commercial Treaties Acts of 1914 and 1916 declare these wines to be the produce respectively of Portugal and the Island of Madeira, and they penalise as a false trade description the application of the terms "port" or "madeira" to any other liquid, although those British Dominions overseas which are developing wine-making industries are known to deprecate the limitation.

Non-alcoholic Wine.

Does wine necessarily mean something alcoholic? Apparently not. The Public Health (Preservatives in Foods, &c.) Regulations, made last year, schedule a list of articles which may contain a limited quantity of preservative, and they allow a small proportion of benzoic acid to be added to "non-alcoholic wines." This expression was quoted in a prosecution at Salford last August when a confectioner was summoned under the Sale of Food and Drugs Acts for selling a "meat and malt wine" not of the nature, substance, and quality demanded. In the Wincarnis case at Brighton the defendant owed his conviction to the fact that the liquor contained too much alcohol; in the Salford case it was complained that the meat and malt wine contained no alcohol at all. The city analyst certified that a sample showed 81·2 per cent. of water, 16·4 per cent. of sugars, and 2·4 per cent. of extractive matters. In this last item was 0·06 per cent. of phosphoric anhydride, indicating traces of a mixture of meat and malt extract. It was stated that a genuine meat and malt wine should have at least 5 per cent. of a mixture of equal parts of meat and malt extract with a wine basis. The sample was entirely deficient of wine; it was sold for 4*s.* 6*d.* and a witness estimated the total value at less than 6*d.*, bottle and all. The bottle was labelled "non-alcoholic," but the prosecution contended that wine means the fermented juice of the grape, and is not wine unless it contains alcohol. The defence was that there was no legal standard for a meat and malt wine, and that the prosecution had not established that the bottle in question was not a meat and malt wine, however inferior. The defence also relied on the use of the words "non-alcoholic wines" in official publications, as showing that wine need not contain alcohol. The stipendiary magistrate seemed to think the public had been imposed upon but felt obliged to acquit the confectioner in view of the legal points raised. Those who have to study the Sale of Food and Drugs Acts would probably agree that it is high time that this series of enactments, going back over 50 years in which neither science nor public opinion has stood still, might well be revised in the light of modern requirements. Sir Mackenzie Chalmers, a former Parliamentary counsel, has placed it on record that he once suggested to a departmental official that these statutes should be consolidated and reduced into one orderly document. "What is the necessity?" was the reply; "we know all about the Acts within the department, and the public finds out in the police-court!"

Enforced Resignation from Hospital Staff.

On Oct. 27th a civil action was tried before Mr. Justice Branson in Liverpool, in which the plaintiff, Dr. Isaac Harris, sued the ex-chairman of the lay committee of the Northern Hospital. Dr. Harris first became connected with the Northern Hospital in 1913 as a clinical assistant on the medical side. His interests lay chiefly in diseases of the heart, and when a cardiograph was installed he was put in charge of it, and in 1919 was formally recognised as head of the cardiographic department. Apparently there was friction between Dr. Harris and other members of the hospital staff, culminating in a refusal on their part to allow Dr. Harris to examine certain patients and the refusal of Dr. Harris to take cardiograms and issue reports without such examination. About this time Dr. Harris was appointed hon. physician to the newly-established heart hospital, and it was suggested that it was inadvisable that he should hold both positions. Finally at the annual meeting in this year, when the names of the medical staff were submitted for re-election, the name of Dr. Harris was omitted from the list. His post being in this way rendered vacant another medical officer was subsequently appointed. Dr. Harris maintains that he asked for a committee to inquire into the offences he was alleged to have committed, but that no notice was taken of his request. During the whole forenoon the facts were gone into before the court, but finally in the afternoon it was announced that the matter had been arranged. The judge in court made it evident that for him two points stood out above the others: first, that whereas it was part of his duty to take cardiograms, Dr. Harris had refused to do so unless permitted also to make a clinical examination of the patient; secondly, that Dr. Harris "could not regard it as an understood condition that his appointment should be permanent, when the letter of appointment laid down expressly that it was subject to annual confirmation." A statement was made on behalf of the committee of the Northern Hospital indicating that no suggestion whatever was being made against the capacity, ability, and integrity of Dr. Harris, who had done great and

valuable work for the hospital, which was cordially appreciated by the committee. They also appreciated that the doctor's grievance really was that his case had not been inquired into, though in their view it had been fully and anxiously investigated.

Diseases of Animals Acts: Ignorance of the Law.

The difficulty sometimes experienced by the public in finding out the law was illustrated by some cases under the Diseases of Animals Acts reported in the *Times* during October. An Isle of Wight farmer was summoned for breaking an Importation of Animals Act Regulation by failing to isolate for six days a pedigree bull brought from the Channel Islands. The clerk of the justices protested that he himself and others who had studied the law all their lives were not informed of such Regulations but had to go and look at the notices posted up. These Regulations came in such masses, he said, that those concerned could not make themselves acquainted with them fast enough. The chairman of the magistrates remarked that it was very necessary that the Regulations should be observed and he fined the farmer 10*s.* as a warning to others. Later in the month another farmer was summoned at the Highgate police-court for failing to give notice with all practical speed of the existence of foot-and-mouth disease on his farm at Whetstone. The farmer said he had no knowledge of the disease; he thought his cows were lame from standing in tarred water which had flowed from the road on to his field. He was fined £25, with a suggestion from the bench that there should be no deduction from the compensation to be paid him for the cows. The outbreak was said to be due to the presence on the farm of straw used for packing bananas imported from the Canary Islands. A greengrocer who had removed the straw from his premises in Finchley to the farm at Whetstone was summoned for breach of the Minister of Agriculture's Order in this respect. The defendant pleaded ignorance of the Order; the magistrate admitted that he himself was unaware of it. The defendant was fined 5*s.*, the prosecution being treated as having been instituted for the sake of giving publicity to the Order. Critics of the Ministry of Agriculture's Regulations and Orders, which admittedly are issued suddenly and in large numbers whenever outbreaks of cattle disease are reported, must remember that it is essential that the Ministry should make swift use of its powers of issuing Orders. The Ministry, as a matter of fact, sets other departments a good example in the efforts it makes to acquaint all concerned. If farmers want to eliminate cattle disease, they must display the necessary interest and vigilance.

VIENNA.

(FROM OUR OWN CORRESPONDENT.)

The Cardiac Hormone.

Prof. Ludwig Haberlandt has recently given the Vienna Medical Society an interesting account of some experiments on the heart which, he claims, have established the existence of a cardiac hormone. The fact that in certain animals (e.g., frogs) the heart continues to beat automatically for some time after removal from the body has not hitherto been satisfactorily explained. Work on the subject has been done by Engelmann, who suggested that the heart-muscle itself must produce substances which regulate and stimulate contraction, but was unable to demonstrate them, and by Löwi who succeeded in isolating from the heart a substance which had some action on the muscle itself. In his own experiments Prof. Haberlandt placed hearts, freshly taken from frogs, in warm saline solution, where they continued to beat for some time. He then removed part of the sinus and placed it also in salt solution, where it beat in the same way. Here he discovered the remarkable fact that the beating fragment imparted its property to the solution. Hearts which had been removed up to three days previously and were apparently quite dead were found to recover on being put in the solution in which the sinus had been beating. They began to beat again. In other words, the fragment of the heart had given off into the saline solution a substance which irritated and resuscitated apparently paralysed heart-muscle. Numerous control experiments, it is said, have established the fact that in the cardiac sinus, as well as in the floor of the ventricle, a hormone is formed that is the cause of the cardiac contractions. It produces these contractions in non-beating hearts; it increases the rate of those which are slowly beating; it strengthens the force of cardiac movement. Prof. Haberlandt calls this hormone "sinus hormone." It is soluble in physiological saline and alcohol, but insoluble in ether, and it is very resistant to heat and cold. This shows that it is not an albuminoid body. It is not identical with adrenalin, for it does not contract the blood-vessels, its action being rather to dilate them. Prof. Haberlandt hopes that he will shortly find a practical method of obtaining the hormone from the hearts of slaughtered animals in quantities sufficient for its therapeutic use in medicine. As was pointed out in the discussion following his demonstration, the isolated hormone would be the physiological cardiotonic in a large variety of pathological conditions.

A New Fattening Cure.

At the same meeting Dr. F. Depisch showed several patients whose weight, by a simple method, has been rapidly increased after debilitating conditions. It is similar to the method of Falta, who injected insulin in order to increase appetite, but in this new treatment the insulin of the patient's own body is, so to speak, mobilised. In a non-diabetic person a dose of 100 g. of glucose, dissolved in 1000 c.cm. of water, is followed by a remarkable drop of the blood-sugar after an initial rise. Three to four hours after the ingestion of the glucose the drop is at its lowest, the blood-sugar falling below its initial value. The rapidity and amount of the drop is an index of the irritability and activity of the tissues producing insulin. Normal patients show at this period a pronounced hunger, and even distinct symptoms of hypoglycæmia, such as tremor, perspiration, and palpitation. Dr. Depisch finds that people with poor appetite and low weight, when given a sugar breakfast as described above, develop the hunger of a wolf, and are able to take a surprising amount of ordinary food about four hours after the ingestion of their sugar. Ordinary sugar is given instead of glucose and it is dissolved in weak tea with lemon. The increased hunger is due to an excessive production of insulin, stimulated by the large dose of sugar. In some instances the increase of hunger does not appear before the third or fourth day of the experiment—i.e., not until the organ has been trained to overwork. The increased output of insulin and the improved appetite continue for some time after the sugar breakfast has been stopped, and the patients thus easily and rapidly gain in weight. In certain patients the method is not successful; some of them refuse to take the large quantities of sugar, and in others the insulin-producing tissues are incapable of an adequate response, so that no hypoglycæmia occurs. Dr. Depisch regards as unsuitable for the treatment those cases with pyrexia, toxic conditions, or gastric irritations. His experiments go some way towards justifying the opinion of those who believe that the ingestion of carbohydrate in diabetes sometimes improves the activity of the insular organ.

The Treatment of Quinsy.

The very frequent occurrence of peritonsillar abscess as a complication in the present epidemic of "influenza" has prompted the Vienna Medical College to devote a meeting to the subject, at which Prof. O. Mayer and Prof. O. Hirsch laid down the following lines of treatment. The site of the abscess decides the method of attack. Those which originate from the upper pole of the tonsil, making the anterior

pillar bulge forward, should be opened at the mid-point of a line drawn from the base of the uvula to the last molar tooth. The incision should be at least three-quarters of an inch deep, for the mucous membrane is very œdematous, and should reach about half an inch outside and below the line mentioned. Once or twice a day the wound should be opened a little with the forceps to let the pus escape, but no other drainage is required. Care must be taken in lancing the abscess not to go too far outwards—this endangers large arteries—nor to go into the tonsil itself, nor to risk damage to the tonsillar artery by going too far inwards. Where there is severe hæmorrhage from such arteries tonsillectomy should be performed at once. Abscesses having their origin at the lower pole of the tonsil generally develop laterally or backwards. Backward extension causes bulging of the posterior pillar, and the abscess can be opened there, whilst lateral extension of the inflammation produces very severe symptoms—pain, impossibility of swallowing, œdema of the tonsillar region, and fixation of the lower jaw. The abscess should be opened as soon as possible at the point of incision described above. If no pus is found there tonsillectomy is indicated, for otherwise there is a risk of a dangerous deep phlegmon of the neck or mediastinitis. If tonsillectomy is impossible or if it is already too late an incision should be made along the anterior border of the sternomastoid muscle, going down to the fascia ensheathing the great blood-vessels, for this is the route along which the abscess goes to the mediastinum. Sufficient drainage is very important after opening the abscess here. Hæmorrhage, even of a minor degree, where there is a peritonsillar abscess, should raise a suspicion that there has been erosion of a blood-vessel; compression or even ligature of the carotid artery (external or common) may be needed. In lancing a quinsy ethyl chloride or ether may be given as an anæsthetic; local anæsthesia is of no use. If abscess-formation is certain it is a mistake to open too early, for if the incision is made before the abscess has truly formed the patient suffers more than before.

Fewer Medical Students.

The entries for the winter term at the University show a distinct drop in the number of medical students matriculating, as well as a general decrease of undergraduates. This is due partly to the unfortunate economic situation of the medical profession, and partly to the fact that many students from Eastern countries (Poland, Roumania, Serbia, Greece) are going to other universities, where there is no restriction placed on their dissection work and where the laboratories and other institutes offer them free experience. First-year foreign students especially are apt to find difficulties in their studies here.

ROYAL MEDICAL BENEVOLENT FUND.—At the last meeting of the committee 58 cases were considered, and £784 9*s*. voted to 52 applicants. The following is a summary of some of the cases relieved :—

Widow, aged 59, of M.D. 1889 who practised in Lancashire and died in 1914. Three children. One son, aged 26, has been in a mental hospital since July, 1925. Youngest daughter, aged 22, is a probationer in a hospital, and the applicant is dependent on eldest, aged 23, who earns £2 a week as a clerk. Up to three years ago applicant maintained herself. Voted £26 in 12 monthly instalments.

M.D. Glasg. 1886, aged 68 who practised in Scotland and retired on account of ill-health and deafness. Widower. Four children. Now lives with son, who is a minister with a small stipend. Daughter only earns £75 a year as a secretary. Asks for a grant to enable him to contribute towards his own board and of his personal attendant. Voted £40 in 12 monthly instalments.

Wife, aged 55, of L.S.A. 1900 who practised in the south, and owing to general paralysis is now in hospital. Applicant's five step-children and her own daughter have allowed her about £40 since January. Rent £9 12*s*. Asks for cost of husband's maintenance. Voted £30 in 6 monthly instalments.

Widow, aged 58, of L.R.C.P.I. 1898 who practised in Kent and died in 1904. Only income is rent from a house £65 per annum net. Has one room at a cost of £31 4*s*. including coal. No children. Insufficient income to cover necessities and clothing. Voted £10 in 2 instalments and clothing.

Subscriptions may be sent to the Treasurer, Sir Charters Symonds, K.B.E., 11, Chandos-street, Cavendish-square, W.1.

Public Health Services.

HOME TREATMENT OF MILD SCARLATINA.

A SHORT while ago we announced a change of policy in the allocation of fever beds at the hospitals of the Metropolitan Asylums Board, the effect of which will be to make the home conditions the ruling factor in the decision so soon as 75 per cent. of the available hospital beds are occupied. The borough medical officer of health will then select at his discretion from the notified cases of scarlatina or measles such as are likely to benefit most from hospital treatment The decision was taken on a report as yet unpublished presented to the Board on Feb. 20th last by Dr. F. Foord Caiger, who considered that the only valid objections which could be urged against giving preferential treatment to measles over scarlet fever were, first, that many employers, and most school authorities, declined to allow their employees to come to work or, in the case of children, to attend school, so long as a case of scarlet fever was present in the home. This he felt to be undoubtedly a difficulty, and one which has to be faced. In the better-class homes, where the patient can be isolated, there is not much risk of infection being conveyed by a contact, particularly if an adult, so long as care is exercised in respect of such matters as wearing an overall, washing of hands, and the adoption of ordinary precautions. A leaflet might, he thought, be furnished by the medical officer of health, and delivered at the house by the sanitary inspector on his first visit setting forth the precautions to be observed and, if satisfied that such were being taken, a certificate to that effect might be given by the medical attendant, to be handed by the parent or other person concerned to the employer. Some employers would, no doubt, be unwilling to accept this assurance, but others would, and their number might be expected to increase as the practice became more extended. Cases where the home conditions were such as to preclude the possibility of isolating the patient, or where a confinement was expected in the household, as also those occurring in tenement houses or institutions, would need special consideration and would justify selection for removal to hospital, as in the case of measles under the present system.

Secondly, it is obvious that, should the number of beds allocated to scarlet fever be insufficient for the isolation of all cases for which removal to hospital were sought, a selection of the cases regarded as suitable for admission would have to be undertaken, and this, it had been urged, would be attended with considerable difficulty. The fact that the public and many medical practitioners, relying on past experience, have come to expect the removal to hospital of every case of scarlet fever on application being made, and that a policy of selection is consequently inadmissible is, however, in Dr. Caiger's opinion, an objection to which but little weight should be attached. New conditions call for new measures, and public opinion would have to be educated accordingly. Selection in the case of scarlet fever should not, he concludes, present the same difficulties as in the case of a disease like measles, where the proportion of cases for which hospital treatment can be provided, compared with the total number of cases for which it is required is so much smaller, and where, owing to the average severity of the disease in the early stage being so much greater, removal to hospital at the earliest possible moment is indicated.

INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED OCT. 23RD, 1926.

Notifications.—The following cases of infectious disease were notified during the week :—Small-pox, 126 (last week 132); scarlet fever, 1863; diphtheria, 1150; enteric fever, 60; pneumonia, 763; puerperal fever, 36; puerperal pyrexia, 115; cerebro-spinal fever, 6; acute poliomyelitis, 68; acute polio-encephalitis, 21; encephalitis lethargica, 37; dysentery, 10; ophthalmia neonatorum, 141. There were no cases of cholera, plague, or typhus fever notified

during the week. One case of small-pox was reported from Islington, the remainder from the northern counties. The reported cases of poliomyelitis and polio-encephalitis are still on the increase, the counties reporting more than 3 of the 2 diseases taken together being Kent, 37 (33 from Broadstairs, 2 from Ramsgate, 1 each from the rural districts of Bridge and Milton); Lancaster, 4; Rutland, 5 (Oakham); Warwick, 7; Leicester, 4 (rural districts of Hinckley and Melton Mowbray). Several counties reported isolated cases of polio-encephalitis without poliomyelitis.

Deaths.—In the aggregate of great towns, including London, there was no death from small-pox, 1 (0) from enteric fever, 6 (0) from measles, 5 (2) from scarlet fever, 19 (5) from whooping cough, 40 (13) from diphtheria, 159 (33) from diarrhœa and enteritis under 2 years, and 54 (18) from influenza. The figures in parentheses are those for London itself.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

THE following are some of the statistics of four county boroughs for 1925 :—

Name of county borough.	Estimated mid-year population (R.-G.).	Birth-rate.	Death-rates per 1000 of the population.					Death-rates per 1000 births.	
			All causes.	Tuberculosis.	Cancer.	Resp. diseases with influenza.	Heart disease.	Infant mortality.	Maternal mort. from childbirth.
Leeds	472,900	17·3	12·8	1·27	1·28	2·7	1·4	91	5·5
Birkenhead ..	155,500	20·5	12·1	1·01	1·28	2·6	0·9	92	4·7
Blackburn ..	126,900	14·9	13·9	0·87	1·26	3·3	1·7	98	5·7
Northampton.	93,780	15·6	11·9	1·04	1·49	1·9	1·3	67	6·1

Leeds.

Dr. J. Johnstone Jervis expresses his regret that at the end of five years the tuberculosis scheme is still incomplete. Nearly 200 persons, many of whom are insured, are on the waiting-list for the sanatorium. Either available beds at existing institutions must be increased or an entirely new sanatorium built. The latter, though costing more, is the better proposition. A system of open-air schools is also needed for children of the delicate or pre-tuberculous type. Another matter demanding attention is a comprehensive scheme for dealing with cripples, for which the education and health committees must coöperate. The amalgamation of the public medical services carried on by the two committees has also not yet been consummated.

The Leeds maternity hospital has accommodation for 75 women. It is proposed to increase the beds to 102, and to make great improvements in the administrative facilities. During the year 63 of the pupil midwives trained there entered for the C.M.B. examination and 59 obtained the certificate. The hospital also maintains, by agreement with the corporation, five district midwives, who work under the supervision of the resident medical staff. During 1925 the total births attended through this institution numbered 2355, 844 of which were extern cases. In addition to this about 100 maternity cases were admitted to the beds subsidised by the corporation in Poor-law infirmaries. The total births in the city numbered 8180.

The question of smoke abatement has received attention. The percentage of chimneys emitting more than three minutes per hour of dense smoke was 2·1, as compared with 1·7 in 1924 and 3·3 in 1923. These three years show a great improvement on the records for 1922 and 1921, which were 7·1 and 8·6 respectively. Circular letters were sent to the owners of offices, warehouses, shops, and hotels, asking them to consider the abandonment of raw coal and the adoption of smokeless methods. The West Riding Regional Smoke Abatement Committee has produced a report containing important recommendations to its constituent authorities and to the Government. The recommendations include more systematic observation of chimneys and the adoption of a black smoke limit not exceeding two minutes in the half hour; also a reduction in the price of electricity and the adoption of smokeless methods in new houses wherever possible.

More interest has been taken in the clean milk question. At the end of 1924 the daily sale of graded milk in the city was only 30 gallons. At the end of 1925 the amount had increased to 850 gallons, including 30 gallons of "Certified," 100 of "Grade A (T.-T.)," and 720 of "Grade A" milk. A year or two ago a system of score cards was adopted for the dairy farmers, each farmer being informed of the result. Following this, on Jan. 1st, 1925, a "clean" milk competition, using these score cards, was launched and continued for the whole year. The routine included visits by the veterinary inspector and the cowsheds inspector, who saw the cows milked, &c. The samples taken were tested for visible dirt, keeping properties, the total number of bacteria, and the presence of *Bacillus coli*. 125 of the 130 dairy farms in the city and two outside farms took part in the competition. Thirty of the city farms were found to be producing milk of "Grade A" standard. It is proposed to award first-class certificates to producers obtaining over 75 per cent. total marks, and second-class certificates to those who obtain between 60 and 75 per cent. Only five of the competitors failed to qualify for any certificate. The two corporation farms, which supply "Grade A" milk to the municipal institutions, obtained 90 per cent. of marks. Of the 2039 cows in the city, six were found to have tuberculosis of the udder and five generalised tuberculosis; 9·8 per cent. of the cows were reported to be dirty at the time of the inspection.

Mussels from Millom in Cumberland were found on examination to be sewage tainted and have been excluded from sale. Two small special outbreaks of scarlet fever occurred. One affected 26 persons working at a ready-made clothing factory and arose from a missed case in the person of one of the factory hands. The other outbreak was traced to a milk-supply outside the city. A campaign has been in progress to equip a cancer research laboratory at the university and £75,000 have been already raised for the purpose. In 1924 the corporation agreed to pay the fees of obstetrical consultants called in by general practitioners, but up to now this scheme has only been used 12 times, at a cost of £42 17*s.* 6*d.*

"Housing is still the most serious and urgent of the social problems," although there is renewed activity amongst private house-builders. Of the 960 houses erected by private enterprise, 583 were subsidy houses. Experiments are being made with all-gas and all-electric houses. Dr. Jervis regrets that the house shortage has made progress with schemes for unhealthy areas impossible.

Birkenhead.

Dr. D. Morley Matthieson enumerates several advances in his 1920–25 survey. Thus motor ambulances have replaced horse-drawn; electric light has been installed at the fever hospital; the sanatoriums at Thingwall (now used chiefly for children) and Burntwood (Joint Cheshire) have come into use; the health services have been coördinated with the dual advantage of making the work more interesting to the staff and of allowing the services to be extended without increase of staff. The great lack, however, is suitable central premises instead of the five separate buildings, "mostly inconvenient and unsuitable," at present in use. The corporation subsidise 12 beds for surgical tuberculosis at Leasowe. The children who were discharged after an adequate course of treatment during the years 1920–25 numbered 42, and investigation at the end of 1925 gave the following results :—

Thirty-six cases (including 25 "bones and joints," 5 "abdomen," and 6 "peripheral glands") were cured. In 4 cases (2 bones and joints and 2 peripheral glands) the

disease was not arrested, and in 2 cases (bones and joints) death had occurred.

Up to the autumn of 1922 the V.D. clinic at the borough hospital was conducted by the hospital staff, but since that date it has been carried on by the medical staff of the health department. Every year improvement in methods of diagnosis and treatment have been made and close association kept up with other branches of the public health work. Thus Dr. Mary Deacon, who is in charge of the antenatal clinic, also conducts the sessions at the V.D. clinic at which women and children are treated, and school-children with the later manifestations of congenital syphilis are referred from the school clinics. The most prominent feature of the mental deficiency scheme is the failure to obtain sufficient accommodation in existing institutions for persons who cannot be properly cared for at home. The primary duty of ascertainment has been well carried out in Birkenhead, says Dr. Mathieson, "but ascertainment and classification are of little value unless they are followed by suitable care and control, and, where necessary, segregation." And he goes on to relate the steps which have been taken since early in 1924 and culminated at the close of 1925 by an agreement between the Cheshire County Council and the county borough councils of Birkenhead, Chester, and Wallasey to form a joint committee under the Mental Deficiency Act, 1913, for the purpose of providing an institution to accommodate 500 mental defectives. It is considered that a site near Chester or in the Wirral will be the most convenient.

The antenatal clinic conducted by Dr. Deacon shows a gradual increase of work. During 1925 48 women attended in their first pregnancy and 271 in a subsequent pregnancy. Dr. Deacon is conducting an investigation into the chemical composition of the milk of nursing mothers, which is not yet completed. When the dental scheme for the school-children was put into operation in 1921 it was intended to extend it until it covered the whole school population. Owing to financial reasons no extension has yet been made, with the result that while 6000 of the 24,000 school-children "have in the main clean mouths and sound teeth," 90 per cent. of the remainder have teeth requiring attention, and "large numbers suffer from untreated oral sepsis." Owing to an unusually large number of diphtheria admissions to the hospital and the occurrence of several cases among the staff and of cross-infection in the scarlet fever wards, the "Schick" test was adopted for the staff and for cases of scarlet fever admitted.

Blackburn.

Dr. Oscar M. Holden, who took up his duties in the middle of the year under review, points out that the population of Blackburn reached its zenith in the first decade of the century. At the Census of 1911 it was 133,052 and at the 1921 Census it had dropped to 126,643. The local Census taken on March 14th, 1926, gave a population of 126,497. With this declining or stationary population it is not surprising to learn from the report that housing and overcrowding are less urgent problems than elsewhere. Nevertheless, there is a considerable waiting-list for corporation houses. The problem of houses let in lodgings remains unsolved and there is a growing evil of caravan dwellings. Dr. Holden deplores the fact that the by-laws in force for the former do not give powers to the corporation to enforce annual registration and better cooking facilities. The rents charged are generally exorbitant, and the accommodation, furniture, and bedding very unsatisfactory. There is a growing tendency to use caravans as a substitute for houses. A business is made of buying caravans, placing them on vacant ground, and letting them to tenants at 5*s.* to 10*s.* a week. Frequently there is no proper water-supply or closet accommodation and the ground around the caravans becomes littered with refuse. But the actual inmates are reported to be "particularly healthy."

The respiratory group of diseases bulks largely in the death returns and Dr. Holden thinks climatic conditions coupled with a dirty atmosphere are largely to blame. Tables are given in the report to show the relative cost of heating rooms by various methods. For continuous heating an open fire with low temperature coke comes out well. There are 183 factory chimneys in the town, 100 of which are provided with smoke-consuming appliances; 190 observations were made during the years, and in 39 black smoke was emitted in excessive quantities. The standard adopted in Blackburn varies from four minutes black smoke in the hour for a chimney serving one boiler to seven minutes for a chimney serving four or more boilers.

A high maternal mortality is common to Blackburn and other textile towns. The rate for 1925 was the same as the average for the last nine years—namely, 5·7. The municipal maternity home has accommodation for 20 cases and towards the end of the year the medical officer of health was empowered to remit the minimum fee of 1½ guineas per week in cases of proved necessity. An antenatal clinic was begun in 1921 and is conducted by the assistant medical officer, Dr. Ella Mackenzie. The expectant mothers who attended during 1925 numbered 367. The total births were 1902. Of the total births 285 took place in institutions, 53 in midwives' houses, and of the confinements in private houses 37·1 per cent. took place in the kitchen or living-room. There were 74 still-births, equivalent to 3·9 per cent. of the registered live births, and the certified causes were as follows: 19 mal-presentations, 12 albuminuria, 3 ante-partum hæmorrhage, 2 difficult labour with instrumental delivery, 12 ill-health of mother, 1 malformation of fœtus, 2 of fall, and 23 not known. Ophthalmia neonatorum has not caused blindness in Blackburn for four years. Wet milk is not supplied through the centres, as it is found that when dried milk is supplied the babies are brought regularly to be weighed and examined. The fourth clean milk competition was held from January to March, 1925. There were only five entrants, however, and there are 68 inside and 95 outside dairy farms which retail milk in the borough. Of 94 samples of mixed milk examined at Liverpool University for tubercle, three gave a positive result and in eight cases the experimental animal died before the test was complete. One of the positive cases came from an outside farm which supplied "Certified" milk. The two other positive samples also came from outside farms, but in neither case was a tuberculous udder found. At one farm a cow had been sold, but at the other nothing was found to account for the infection of the milk.

The accommodation for tuberculous patients at corporation hospitals is to be improved by the provision of wide verandahs. Apart from the window-cleaning business managed by the Charity Organisation Society for ex-sanatorium patients, there is no system of after-care, and there is, says Dr. Holden, great need for it.

Northampton.

Dr. J. Doig McCrindle criticises the scavenging arrangements in his borough. One of the tips caused an intolerable smell in the neighbouring streets during the hot weather and a plague of flies. Owing to the utterly unsuitable receptacles for house refuse put out on the street and to the uncovered carts used, the condition of the streets on a dry windy day is a frequent source of complaint. Industrial smoke does not cause much pollution of the atmosphere in Northampton as the power in the factories is mostly supplied by gas or electricity.

Milk adulteration is apparently profitable in Northampton. In one case of 9·6 per cent. of added water a fine of 16*s.* with 4*s.* costs was inflicted. In another case a retailer was supplying milk 37 per cent. deficient in fat and with 14·1 per cent. of added water. On sampling the milk in course of delivery to the retailer the dairy farmers' product was found

to be 9 per cent. deficient in milk-fat and to have 13·3 per cent. of added water in one sample and 15·4 per cent. in another. The time-honoured defence of a leaky cooler was put in and a fine of £4 15*s.* with 5*s.* costs was inflicted. After being free from small-pox for 20 years Northampton had an outbreak of the mild type. There were 23 cases with no deaths. The revision of the register of notified consumptives has resulted in the removal of 75 persons as being cured and of 113 persons in the case of whom the diagnosis was not established.

SCHOOL MEDICAL SERVICE.

Name of town.	No. on roll.	Av. elem. school attendance.	No. of routine children examined.	No. of special examinations and re-inspections.	Percentage of children found on routine examination requiring treatment.*
Carlisle	7895	6858	2819	7628	27·0
Tunbridge Wells	—†	3185	1185	2928	29·6
Torquay	3669	3123	1086	6180	18·1

* Excluding uncleanliness and dental defects.
† Not given.

Carlisle.

Dr. Joseph Beard draws attention to the invaluable aid given to the local authority by the Carlisle Council of Social Service which provides treatment for many ailing children at the convalescent institution at Silloth and sends others to recuperate at various homes; the council is now arranging to provide treatment for cripples in conjunction with the surgical staff of the Cumberland Infirmary. This help is doubly welcome, since there are at present no facilities in the city for dealing with either physically or mentally defective children. Open-air education is provided for 60 debilitated children at Newtown, where they are visited weekly by the tuberculosis officer, and each child in attendance is supplied with two meals a day. The excellent practice of supplying necessitous children with meals cooked at the domestic centres is in vogue. The council's scheme includes ophthalmic treatment and X ray exposures for various skin complaints as well as minor ailment and dental treatment. Operations for tonsils and adenoids and presumably for ear disease are carried out at the infirmary. Statistical tables show that there has been no diminution in verminous conditions of the head during the past few years. The attendance of parents at routine medical examinations is small (51·3 per cent.), but shows an increase from 48·4 per cent. in 1924.

Tunbridge Wells.

Dr. F. C. Linton points out the unsuitability of many of the present school buildings which are badly designed and unhygienic, with insufficient lighting and inadequate and unheated cloakrooms. Children arriving with wet clothing and feet have no means of drying them. There is little or no circulation of fresh air and sunlight is excluded. Playground accommodation is inadequate and the play instinct which determines growth and development is stifled, and since there is no director of physical exercises, games are played in haphazard fashion. Of course, these conditions are not peculiar to Tunbridge Wells, but they are specially noticeable in a health resort. Dr. Linton has good reason for his belief that such conditions are important factors in keeping up the incidence of enlarged tonsils and adenoids as well as much catarrhal and general affections. The coördination of the various health services in the town is good and the school medical officer supervises the debilitated children under school age. The success of a small, privately-run venture has encouraged the education authority to arrange for an open-air school on more ambitious lines and an orthopædic scheme is now coming into operation, while a beginning has been made to provide suitable education for the feeble-minded by conveying ten cases to the special school run by the Kent educational authority in Tonbridge.

Torquay.

Dr. T. Dunlop includes in his report the findings of Dr. J. V. A. Simpson with briefer notes by the oculist and dentist. Dr. Simpson has carried out an investigation on the relationship of rowing and physical fitness. Torquay is the first authority to apply for the permission of the Board of Education for elementary school-boys to take rowing as a part of their physical education. The estimates of fitness were based on Dr. A. G. Woolham's modifications of Flack's breathing tests, and the results were compared with the relative fitness of various types, including some weakly lads from an open-air school. The most valuable single method was the "persistence test"—i.e., the time a column of mercury could be held at a certain level by blowing into a standard tube, the pulse-rate being taken every five seconds. Such investigations are valuable as a foundation for finding tests of physical fitness comparable with the Binet-Simon tests for intelligence. Dr. Simpson also continues his comprehensive records of ventilation, tested by the kata-thermometer. It is expected that the open-air school will materially benefit cases of rheumatic heart affections. An unusual experiment was recently carried out at this school by entertaining a party from a London myope class. Dr. D. Wilson, the ophthalmic surgeon, remarks on the increasing attention paid in Torquay to fusion-training in squint and to the care of glasses. Only one-seventh of the dentist's time is taken up by inspection, the remainder being devoted to treatment, in which the main consideration is the preservation of the permanent teeth. This report contains much of scientific and practical interest.

Obituary.

THOMAS CHURTON, M.D. ABERD., M.R.C.S. ENG.

THE death of Dr. Churton at the advanced age of 87 will come as a real sorrow to a large circle of professional and lay friends, as well as to the general public of Leeds. Born at Stafford, he was educated at Shrewsbury and afterwards became a student of the Leeds School of Medicine. His mother, who was left a widow shortly after his birth, became matron of the old infirmary at Leeds and, like her own mother, who had been matron at the Salop Infirmary in Shropshire, did good work in that capacity. Young Churton became one of the junior residents at the infirmary, and in 1862 took the diploma of the Royal College of Surgeons. For a good many years he was in general practice at Erith, but he always aimed at consulting practice and for this he prepared himself by making regular visits to London several times each week and attending the practice of Guy's Hospital and other teaching centres. He then threw up his general practice and went for a year's intensive study to Aberdeen University where, under the conditions then in force, he graduated as M.B. in 1876 and M.D. in 1877. In after years, Dr. Churton often spoke of the pleasures of this time at Aberdeen and of the kindness which he received from everyone at the University and infirmary. In 1879 he was elected honorary physician to the General Infirmary at Leeds, becoming colleague to Dr. Clifford Allbutt—as he then was—and to Dr. J. E. Eddison. He remained a member of the full staff till 1919, and during all that time was one of the most assiduous of honorary officers, devoting himself heart and soul to the welfare of the patients entrusted to his care. He was lecturer on medicine to the Yorkshire College when that College was a constituent part of the Victoria University, and was also on the staff of the old Leeds House of Recovery, which was one of the early fever hospitals of this country,

having been founded in the year 1801. He did a great deal of work among the labouring classes when he was on the honorary staff of the Leeds Public Dispensary, and he was consulting physician to the Batley Cottage Hospital.

The Leeds and West Riding Medico-Chirurgical Society was started in 1872 and Dr. Churton became a member in 1876; he acted as secretary from 1878 to 1884 and occupied the presidential chair in 1890. His regular attendance, not only during the earlier years of his connexion with the society, but for many years after he had passed the chair, was an example and a stimulus, and the society paid him the highest compliment in its power by electing him an honorary life member on his retiring from active practice. To the work of the society he brought his best in the way of papers and in the exhibition of cases, and his rising to take part in any discussion was always welcomed by the members, who were captivated by the charm of his voice, by his humour, and by the sincerity and earnestness which he always showed on these occasions. He did not publish much, but whatever he wrote was notable for its thoroughness.

The memory of Dr. Churton will long be preserved by his colleagues of the medical profession in Leeds as that of a high-minded man, conscientious in his work, and free from any trace of self-seeking.

CUTHBERT BALFOUR PAUL, M.B., F.R.C.S. EDIN.

WE have to record the death of Mr. C. B. Paul, of Carlisle, surgeon to the Cumberland Infirmary. At the beginning of last month, whilst making a tour of Dutch hospitals with a party of English surgeons, Mr. Paul contracted erysipelas, and on Oct. 25th he died of septicæmia at Amsterdam, being then 49 years of age.

Cuthbert Balfour Paul was the son of Sir James Balfour Paul, for many years Lyon King at Arms. He was educated at the Edinburgh Academy, which he represented at both cricket and football, and he graduated in medicine at Edinburgh University in 1900. After holding house appointments at the Royal Infirmary and the Edinburgh Hospital for Sick Children, he became private assistant to Sir Harold (then Mr.) Stiles and worked with him in that capacity for six years. In 1903 he took the diploma of F.R.C.S. Edin. and in the following year was elected assistant surgeon to the Chalmers Hospital, Edinburgh, a post which he held until 1908, when he accepted a similar appointment at the Hospital for Sick Children. Here he stayed until 1912 in sole charge of the surgical out-patient department, though the work was briefly interrupted to enable him to spend a short time in Germany and assist Sir Harold Stiles to translate into English the fifth German edition of Kocher's "Text-book of Operative Surgery." In April, 1912, Mr. Paul left Edinburgh and accepting the appointment of assistant surgeon to the Cumberland Infirmary, soon built up a large practice in the Carlisle district. On the outbreak of war in 1914 he offered himself unconditionally for service at the front, but his offer was not accepted and he was posted in England with a Territorial division until, at the urgent request of the infirmary committee, the War Office released him to carry on his work at the Cumberland Infirmary. When a Red Cross Hospital was established at Murrell Hill House he accepted the post of visiting surgeon, and during the remainder of the war did much valuable work there and elsewhere. Mr. Paul took the keenest possible interest in the Cumberland Infirmary and always served it loyally; his considerable abilities inspired great confidence in his patients. Two years ago, as there was no vacancy, the statutes of the infirmary were amended so that he might be appointed full surgeon—a compliment which he obviously deserved. A sociable and generous man, fond of sport and music, he was always ready to take part in the social activities of the district, where so sudden an end to his life will be widely regretted. The funeral service in Carlisle Cathedral on Oct. 29th was attended by a very large number of people.

DAVID LLOYD, J.P., M.B., C.M. GLASG.

Dr. David Lloyd, who died on Oct. 23rd in his sixty-second year, was born at Ty Mawr, near Ruthin, and educated at Ruthin Grammar School. He began his medical studies at the Middlesex Hospital and afterwards proceeded to the University of Glasgow, where he graduated in 1891. His first experience of practice was gained in a populous part of South Wales, after which, in 1892, he settled in Denbigh, where he remained until his death. During this residence in the town Dr. Lloyd held every post of honour and most of the local appointments. He was mayor of Denbigh for two years (1903 and 1904), a justice for the town and county, and a member of the county council, on which he served for a time as alderman. For many years he represented the county council on the board of governors of the North Wales Counties Lunatic Asylum; he was medical officer of health for Denbigh and medical officer to the famous Howells' School there. "Dr. Lloyd," writes a colleague, "was always a student and was most anxious to be up to date. He found time to take post-graduate classes in Liverpool University and paid weekly visits to the Liverpool hospitals for special study. There can be no doubt that his death, at a comparatively early age, was due to his fondness of his professional work and not taking a sufficiently serious view of his own health, as pointed out to him by his medical advisers. His death will be keenly felt by a very large number of friends and patients throughout North Wales." Dr. Lloyd leaves a widow, but no family.

WILLIAM HENRY WHITE, M.D. DUB., M.R.C.P. LOND.

Dr. William Henry White, whose death occurred suddenly on Oct. 22nd, was born at Wexford in 1849, and graduated at Trinity College, Dublin, in arts and medicine. He came to England and settled in practice at Westbury, Shropshire, but found that the work of a large general practice was unsuited to his health. After a necessary rest he decided on a London practice, obtained the M.R.C.P. Lond., and for the rest of his life resided in Weymouth-street, where he practised for 45 years and where he was seeing patients up to the day of his death. Here he acquired, almost from the start, a large number of patients. Very definite in diagnosis, perhaps somewhat dogmatic, his treatment was intensely practical; he was quick to discard useless methods, and had a great hold on the reason and regard of his patients, his striking and impressive appearance being of assistance. His personal influence was as great with the poor as with the rich, largely owing to his cheerfulness and genuine kindness, so that patients crowded to his clinics at the hospitals where he was physician—the Royal Hospital for Diseases of the Chest and the St. Marylebone Dispensary. By his personal friends he will ever be remembered for his charm and powers of sympathy.

In these days he seemed of an older fashion. He was a yachtsman and a great lover of horses, bred his own animals, was for many years a familiar rider in the Row, and till only recently was in the habit of driving his own pair of horses on his rounds. The death of his wife in January last, just after the date of their golden wedding, was a grief from which he never recovered. He is survived by one daughter, Mrs. Constance E. Hughes, and one son.

Sir Arnold Lawson writes: "I should like to add my testimony to the loss the profession has sustained by the death of my old friend, Dr. W. H. White. He was one of the kindest-hearted men I have ever met, always ready to help, and always one whose help was valuable. He had an enormous practice and nobody better deserved success of this kind, for he was a good friend as well as a good physician, with the result that his patients were devoted to him. He was a most able clinician with a strain of originality in his treatment and outlook, which often made his opinion in a difficult case most valuable, and which, too, often brought success after others had failed. One of his strong

points was his independence. He was always ready to take his own line, though it might at the time involve disagreement with his colleagues, and, in my experience, which has extended over many years, he was generally right."

FRANK HUGH BARENDT, M.D. LOND., F.R.C.S. ENG.

Dr. F. H. Barendt, who died at Liverpool on Oct. 28th after a short illness, was well known in Rodney-street as a sound and helpful consultant. The son of Mr. J. E. Barendt, he was educated at Liverpool College and Danzig, and later at the University of Liverpool, where he distinguished himself as a student. In 1885 he qualified for medical practice and two years later graduated as M.B. Lond. The next few years were spent in post-graduate study at Vienna and in house appointments at the Liverpool Royal Infirmary and elsewhere. In 1890 he became F.R.C.S. Eng. and returned to Liverpool, where he was eventually appointed physician in charge of the skin department at the Royal Southern Hospital and surgeon to St. George's Hospital for Diseases of Skin. These posts he held until his death. Dermatology he made his special study and his contributions to its literature were numerous; in 1913 he was vice-president of the Dermatological Section of the British Medical Association. Though never seeking prominence Dr. Barendt entered heartily into all the medical activities of Liverpool. He held office in turn as librarian, editor of the *Journal*, and vice-president in the Liverpool Medical Institution, and he was a strong supporter of the Medical and Literary Society; there were very few subjects on which he had not something of value to say. His own training had been on classical lines and this very clearly moulded his style of speaking, but he was also master of several modern European languages. "In Dr. Barendt," writes a colleague, "family ties seemed unusually deep and strong. As a friend his sympathies were very wide, and many of the younger members of the profession had good occasion to know it. As a man his conduct was modelled by a very definite sense of duty, although a strain of humour and a kindly disposition prevented unnecessary clashing where his ideas did not coincide with those of his colleagues."

Dr. Barendt leaves a widow and several children. His eldest surviving son is a medical student in London.

ARTHUR WILLIAM SCATLIFF, L.R.C.P. EDIN., D.P.H.

Dr. A. W. Scatliff, who died recently at Ditchling Common, Sussex, was the second son of the late Dr. J. Parr Scatliff, of Sloane-street, London, and a member of a family many of whom have been medical practitioners. He studied medicine at St. George's Hospital, and qualified as L.S.A. Lond. in 1876, soon afterwards acquiring diplomas at the Edinburgh Royal Colleges. He then settled at Margate where, as a man of personal charm and wide sympathy, he soon had a large practice; he also acted as medical officer of health and police surgeon for the town. In 1904, however, after 25 years' work at Margate, he accepted an appointment under the Church Missionary Society and went to China, where he was stationed at the Men's Hospital, Futsing, in the Fuhkien Province. Here he remained until 1912 when he came home on furlough, returning again to China early in 1914. On the outbreak of the late war he offered to go home to fill the place of some younger man, but an attack of typhoid fever made his departure impossible. Experiences in China during nearly 17 years seriously damaged his health, and in 1920 he reluctantly resigned his appointment and went back to England; since then he had been almost an invalid. Dr. Scatliff did valuable work in China, and was instrumental in securing the erection of a large hospital in Fuhkien which served a large area. He was the author of a number of contributions to medical journals on various aspects of public health.

"Audi alteram partem."

POST-OPERATIVE BURNS.

To the Editor of THE LANCET.

SIR,—Post-operative burns from the application of hot-water bottles to patients just returned to bed have been and are far too frequent. Such burns should never occur. The surgeon or medical man in charge is the person who should be blamed, not the hospital or the nursing home. It is a most extraordinary fact how medical men will always keep on the old lines and are so slow to analyse facts in a commonsense way.

Consider for one moment the condition of a patient who goes through an operation under a general anæsthetic, where possibly a preliminary injection of morphia has been given. There is more or less unconsciousness and shock. The patient is transferred to a bed with sheets—good conductors of heat—and hot bottles are applied. It is impossible for a patient to react to this heat, even though a nurse's hand can bear the heat quite well. Nurses can bear a great deal of heat, as witness the experienced surgeon who is going to wash his hands in hot water. He "dabs" his fingers carefully in first of all before he plunges the whole hand. The greater the shock the less likely is the patient's skin able to react to hot bottles; and heat which would not burn a healthy, conscious person will burn a shocked one.

Once and once only to my knowledge has a burn occurred in my practice—private or hospital—and many thousand patients have passed through my hands. A post-operative patient should be placed between blankets which have been warmed by hot bottles and these bottles removed when the patient is returned to bed. In many places nowadays a cage can be placed over the patient with an electric bulb attached, a blanket intervening between the patient and the bulb.

After seeing several cases of post-operative burns in consultation—in one case burns of the third and fourth degree on the outside of the thighs in a patient who had been operated on for hydrocele; in another burns down to the bone on both heels where there had been a prolonged mastoid operation; and so on—it makes a very deep impression. In many homes the head nurses tell me that the surgeons order plenty of hot bottles to be packed round the patient, and the great dread the nurses responsible have for after-burn. In bad cases hot bottles only add to the shock, and, considering their wide use, it is a surprise to me that there are so few sufferers. Some years ago I heard a case in court where an action was brought against a hospital on account of such a burn, and the case went entirely against the hospital, not because there was gross carelessness, but because the burn had occurred.

There is another word of warning, and that is where pure carbolic acid is used in such operations as curettage. A drop of this in contact with the skin will produce a burn which very conveniently can be attributed to a hot-water bottle.

I am, Sir, yours faithfully,

Edinburgh, Oct. 22nd, 1926. J. W. DOWDEN.

ASHAMED TO BEG.

To the Editor of THE LANCET.

SIR,—I should be grateful if you would allow me to draw attention in THE LANCET to a matter which is at present in a very unsatisfactory state—namely, surgical and medical attention on medical men (and their families) who are unable from their class of practice to send patients to consultants and specialists. One in this position hesitates to take up the time and give trouble (perhaps necessitating a major operation)

without some *quid pro quo* and the result is that complaints are let go on with much disability or till too late to do anything for radical cure. No fee will be taken if offered and even pressed. A present chosen after much thought may not be valued and the consultant is not pleased. I and my wife have wanted for some time to consult someone, but the existing state of affairs has prevented us from doing so. At present, it amounts to this, that medical men in a certain class of practice are the only people who cannot freely get willing necessary skilled attention even if they are prepared to pay. Could not some scale of fees be arranged that would allow medical men to consult specialists and be welcomed and attended to equally as members of the public paying the usual fee?

I assure you this is a serious matter for a large number of us and I earnestly hope that something can be done to solve the difficulty.

I am, Sir, yours faithfully,

Nov. 1st, 1926. MEDICO.

THE PASTEURISATION OF MILK.

To the Editor of THE LANCET.

SIR,—I do not think it will serve any purpose to enter into further discussion. I remain of the conviction that the milk-supply in this country is dangerous. The total amount of satisfactory milk available does not suffice for the supply of a quarter of a million people, even at the ridiculously low rate of consumption of 0·25 pints per head per day; and the price at which this inadequate supply is vended places it out of reach of any but well-to-do families. It is in pasteurisation, and in pasteurisation alone, that we can see in the immediate future a satisfactory milk-supply for the bulk of the people.

I am, Sir, yours faithfully,

Huddersfield, Oct. 28th, 1926. S. G. MOORE.

THE NOMOGRAPHIC METHOD:

AN ERROR OF OMISSION.

To the Editor of THE LANCET.

SIR,—Dr. W. Feldman has drawn attention to the omission of any reference to his name in connexion with the use of the nomograph for Dubois formula on page 98 of my recent work on "The Fundamentals of School Health." This was entirely accidental, and due to elimination of reference to the nomograph as a graphic method, from the chapter on Statistics, merely retaining the figure as of possible use when transferred to that on Nutrition. Amid the thousands of references there was almost bound to be some error of omission or commission, and in this case the reference should have been to THE LANCET, 1922, i., 273.

I am, Sir, yours faithfully,

Colinton, Oct. 27th, 1926. JAMES KERR.

THE LATE DR. W. H. FLEETWOOD.—After some months of failing health Dr. William Hardy Fleetwood died on Oct. 27th at Hadleigh, Suffolk, where he had been in practice since 1919. He studied medicine at the London Hospital, qualified as M.R.C.S. Eng. in 1905, and acted as house surgeon at the West Ham and East London Hospitals, and as resident medical officer at the Mill-road Infirmary, Liverpool. For some time before the war he was in practice at Hoylake, near Liverpool. He saw service for a long period in charge of an advanced hospital on the Salonika front and retired at the end of the war with the rank of major in the Royal Army Medical Corps. After holding an appointment for a time as registrar at the Kitchener Hospital, Brighton, he went to Hadleigh where he took much interest in the affairs of the town, working for the Hadleigh Athletic Association and the local branch of the British Legion and the local lodge of Freemasons. Dr. Fleetwood leaves a widow.

Medical News.

UNIVERSITY OF CAMBRIDGE.—At a Congregation held on Oct. 29th, the following degrees were conferred:—

M.D.—L. B. Cole.

M.B. and B.Ch.—W. W. McLean, R. H. Metcalfe, and A. T. Worthington.

M.B.—J. H. Hannan.

SOCIETY OF APOTHECARIES OF LONDON.—At recent examinations the following candidates have been successful in the undermentioned subjects:—

Surgery.—H. J. Fordham and W. Johnson, St. Mary's Hospital; R. C. Glover, Leeds and St. Bartholomew's Hospital; R. I. Richards, St. Bartholomew's Hospital; and H. Rundstrom, St. George's Hospital.

Medicine.—A. Heukamp, Gottingen and Royal Free Hospital; W. Howard, Liverpool; T. W. Riseley, Cardiff; and W. D. Williams, London Hospital.

Forensic Medicine.—J. R. S. Bowker, Middlesex Hospital; A. Heukamp, Gottingen and Royal Free Hospital; W. E. Ivers, Manchester; S. Jenkinson and R. W. Wood, St. Bartholomew's Hospital; T. W. Riseley, Cardiff; V. K. Samy, Dundee; and W. D. Williams, London Hospital.

Midwifery.—H. M. de Hartog, St. Mary's Hospital; B. D. Jain and E. H. Waller, Charing Cross Hospital; A. W. Marsden, Birmingham; C. E. Nicholas and W. D. Williams, London Hospital; J. Pattis, Innsbruck and University College Hospital; and D. K. Reynolds, King's College Hospital.

The Diploma of the Society has been granted to the following candidates, entitling them to practise medicine surgery, and midwifery: R. C. Glover, A. Heukamp, W. Johnson, C. E. Nicholas, J. Pattis, and R. I. Richards.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.—An ordinary quarterly comitia of the College was held on Oct. 28th, the President, Sir John Rose Bradford, being in the chair. The following candidates, having passed the necessary examinations, were admitted as Members of the College:—

Drs. Kenneth Blackie Aikman, Robert Dudley Alexander Henry Cohen, William Robert Fitzgerald Collis, Hector Alfred Colwell, James Gordon Danson, Iforwyn Glyndwr Davies, Dinshaw Hormusji Dudha, Vivian Feldman, George Fletcher, Charles Skinner Hallpike, Geoffrey Edward Roper Hamilton, Philip Montagu D'Arcy Hart, Richard Brunel Hawes, Richmond Jeremy, Edgar Hartley Kettle, John Faulks Landreth, Oscar Carl Moller, Austin Threlfall Nankivell, Charles Edward Newman, Arthur Pool, Arthur Digby Porter, Eric Alfred Blake Pritchard, Edward Scott Sobhi Rizkalla Simaika, Sir Eric Stuart Taylor, Paul Biddulph Wilkinson, and Leslie John Witts.

F. H. Maugham, Esq., K.C., was appointed a Senior Standing Counsel on the nomination of the President, vice A. C. Clauson, Esq., K.C., appointed a Judge in the High Court of Justice.—It was resolved that in 1927 a conversazione should be held at the College in honour of the centenary of the publication of Richard Bright's book the date to be fixed subsequently so as to coincide with the celebration at Guy's Hospital.—On the motion of Dr J. S. Fairbairn it was resolved that the Committee of Management should be asked to report to the College on the efficiency of the Examination in Midwifery and Diseases peculiar to Women in the Final Examination of the Conjoint Board.—Dr. H. L. Tidy was elected a member of the Committee of Management in place of Sir William Hale-White who has resigned after eight and a half years of service. Dr Raymond Crawfurd, who retired in rotation, was re-elected.—Two communications were received from the Home Office. The first stated that a committee on the Poisons and Pharmacy Acts is prepared to hear evidence on matters within the scope of the terms of reference to the committee and asked if the College would wish to lay its views before the committee. The second enclosed copies of amended regulations under the Dangerous Drugs Act, and asked the College to nominate a representative to serve on the tribunal for England and Wales, and also a substitute for such representative in case of his unavoidable absence. Sir. W. Hale-White and Dr. J. Fawcett were appointed.—A photograph of a portrait of Nathaniel Johnston, a former Fellow of the College, together with some biographical notes, was received from Dr. A. J. Hall, of Sheffield. The thanks of the College were voted to Dr. Hall.—A report was received from the Committee of Management recommending that certain universities which were removed in 1918 from the list of recognised places of study, graduates of which are admissible to the Final Examination of the Board, should now be reinstated in the list—namely, Graz, Innsbruck and Vienna; Prague; Berlin, Bonn, Breslau, Erlangen, Freiburg, Giessen, Göttingen, Greifswald, Halle, Heidelberg, Jena, Kiel, Königsberg, Leipzig, Marburg, Munich, Tübingen and Würzburg; Budapest. The Committee also recommended that the University of Hamburg be added to the list of recognised German universities, it having been

ascertained that British doctors are admissible to the Staats Examen in Germany and Austria by recognition of their studies and examinations in Great Britain. The Committee also recommended that the Preston and County of Lancaster Queen Victoria Royal Infirmary be added to the list of hospitals recognised by the Board. The Committee's report was adopted.—A report was received from Dr. Dawtrey Drewitt, the representative of the College on the Committee of Management of the Chelsea Physic Garden.—A report was received from Lord Dawson on his conference with the Medical Research Council in regard to the continuation of the publication of the science abstracts.—Books and other donations presented to the library during the past quarter were received and thanks returned to the donors.—The replica of the portrait of the late Sir Richard Douglas Powell, Bart., a former president of the College, given by the Dowager Lady Powell and by Colonel Sir Douglas Powell, was on view.—After some formal College business, the President dissolved the Comitia.

Licences to practise were conferred upon 185 candidates (including 25 women) who have passed the Final Examination of the Conjoint Board. The following are the names and medical schools of the successful candidates :—

Y. Abdel-Messiah, Middlesex ; A. Ali, Cairo and St. Bart.'s ; G. E. Aling, Calcutta and Guy's ; J. H. Anderson, Dublin and Guy's ; G. F. Andrews, Middlesex ; M. C. Andrews, Cambridge and Univ. Coll. ; H. W. Applin, Guy's ; J. M. Ashton, St. Thomas's ; H. Awrounin, Charing Cross ; L. G. Backhurst, Cambridge and St. Thomas's ; Grace Batten, Oxford and King's Coll. ; Rosie B. Becker, Leeds ; M. Behr, Cape and Middlesex ; Florence K. Bibby, Charing Cross ; G. Bindman, Durham ; G. W. Black, Middlesex ; E. J. C. Bockett, King's Coll. ; E. S. Bolton, Cambridge and Leeds ; Susanna M. Bornman, Cape and Royal Free ; J. W. Bottoms, London ; H. W. Bowen, St. Thomas's ; E. Bowen-Jones, Guy's ; H. Brown, Sheffield; F. W. Bradley, Guy's ; J. G. Brandon-Bravo, Amsterdam and St. Thomas's ; W. A. Briggs, Cambridge and St. Bart.'s ; M. Bryer, St. Bart.'s ; R. H. Burns, Cambridge and London ; Izza Caley, King's Coll. ; C. J. N. Cameron, Univ. Coll. ; S. Carnofsky, Cape and Guy's ; J. C. D. Carothers, St. Thomas's ; W. H. Carr, Leeds ; J. R. B. Chatterton, Univ. Coll. ; J. A. Cholmeley, St. Bart.'s ; S. L. A. Clarke, Guy's ; P. F. Cluver, Oxford and St. Bart.'s ; A. Cohen, London ; W. K. Coombes, Bombay and St. Mary's ; D. H. Couch, Guy's ; H. T. Cox, Cambridge and St. Thomas's ; E. S. Curtiss, St. Bart.'s ; R. P. P. Davies, St. George's ; Winifred M. de Kok, Cape and Royal Free ; A. C. de Sousa, Middlesex ; A. A. Digges la Touche, Cambridge and Leeds ; T. A. J. M. Dodd, Oxford and St. Bart.'s ; J. Dywien, Guy's ; Phyllis M. Edgar, Univ. Coll. ; H. M. Elliott, Cambridge and St.Bart.'s ; E. A. R. Ennion, Cambridge and St. Mary's ; H. K. Evans, Middlesex ; Leonora S. Evans, Royal Free ; S. H. Evans, Sheffield; W. G. Evans, Cardiff ; A. W. Fawcett, Edinburgh ; Dorothy D. Forster, St. Mary's ; A. E. Fraser-Smith, St. Bart.'s ; E. G. Frewer, Cambridge and London ; A. H. Gale, Oxford and Univ. Coll. ; Margaret E. J. Gashion, Charing Cross ; J. B. George, St. Thomas's ; Dorothy Gibbs, Charing Cross ; R. M. Gilchrist, Cambridge and St. Bart.'s ; H. K. Goadby, Cambridge and St. Thomas's ; Marjorie Goldrich, Charing Cross ; J. A. Gornall, Manchester ; J. Gough, Cardiff ; R. A. Graff, Middlesex ; E. C. Grant, New Zealand and St. Mary's ; T. L. Griffiths, Cambridge and St. Bart.'s ; H. L. Gulati, Lahore and Charing Cross ; G. S. Hall, Birmingham ; A. C. de B. Helme, Cambridge and St. Bart.'s ; G. F. Henderson, Univ. Coll. ; G. R. N. Henry, St. Thomas's; V. V. H. Hoakai, Guy's ; O. Hooper, Oxford and London ; H. O. Hopkins, Middlesex ; F. S. Hubbersty, Cambridge and Univ. Coll. ; T. C. Hunt, Oxford and St. Mary's ; C. B. Huss, Cardiff and St. Bart.'s ; A. B. Hyman, Guy's ; R. Illingworth, Oxford and Manchester ; A. J. Johnson, Cambridge and St. Bart.'s ; E. C. Johnson, St. Mary's ; Louise A. Johnson, Birmingham ; C. W. Jones and W. T. Jones, Cardiff ; F. E. Kingston, London ; F. Knoyle, Westminster ; L. C. Lancaster, Cambridge and St. George's ; F. R. Langmaid, Middlesex ; C. J. Laviers, Cambridge and St. Bart.'s ; H. W. Lewis-Philipps, Guy's ; D. G. Lloyd, Cardiff and London ; Flora W. Lloyd, St. Mary's ; G. E. Macdonald, Oxford and London ; J. R. Macdougall, St. Bart.'s ; J. McFadzean, Glasgow and London ; W. H. S. McGregor, St. Bart.'s ; W. McLaren, Durham ; H. E. McLaughlin, St. Bart.'s ; W. N. Maclay, Cambridge and St. George's ; E. H. Madge, Univ. Coll. ; P. C. Mallam, Oxford and St. Mary's ; S. M. Mallick, Lahore and Guy's ; C. Mani, Birmingham ; H. Mannington, Middlesex ; J. N. Martin, M. N. Menon, and R. J. Milbank, Guy's ; Barbara H. Mitchell, Royal Free ; Mary S. Mitchell, St. Mary's ; E. R. W. Mons-Glaser, Basle and Middlesex ; H. W. Morck, Durham and Charing Cross ; E. W. T. Morris, Adelaide and St. Thomas's ; T. W. Morris, Liverpool ; E. F. Morton, Cambridge and Middlesex ; B. E. T. Mosse, Cambridge and St. Bart.'s ; B. G. S. Mudali, Madras ; E. A. Nicoll, Cambridge and St. George's ; E. F. D. Owen, St. Bart.'s ; G. E. Parker, Cambridge and St. Thomas's ; N. D. Patel, Univ. Coll. ; L. L. P. Paterson, Melbourne and St. Mary's ; R. H. Pearce and Janet R. Phillips, Birmingham ; R. A. Phillips, Cambridge and St. Thomas's ; C. B. Picken, Guy's ; H. A. Pim, St. Thomas's ; Winifred A. L. Pollock, Westminster ; H. W. A. Post, Guy's ; Margaret M. Price, St. Mary's ; O. L. Prosser, Liverpool ; Lesley M. C. Probyn, Charing Cross ; P. N. Ray, Calcutta and St. Bart.'s ; A. M. Richards, Univ. Coll. ; Hilda M. Richards, Royal Free ; A. H. Richardson, Birmingham ; J. H. O. Roberts, St. Bart.'s ; D. A. Robertson, Oxford and London ; A. P. Ross, King's Coll. ; A. W. L. Row and G. P. Roxburgh, Oxford and St. Bart.'s ; J. A. Rushworth, Manchester ; B. F. Russell, London ; N. A. Saif, Cairo and St. Thomas's ; F. G. A. Shaheed, Cairo and Westminster ; G. C. Shepherd, Charing Cross ; H. L. Shimmin, Manchester ; D. P. Simpson, St. Bart.'s ; J. W. Simpson, Manchester ; B. A. Smith, King's Coll. ; H. Smith, Cambridge and St. George's ; R. S. Smith, Univ. Coll. ; E. R. Smithard, Middlesex ; W. R. C. Spicer, Guy's ; Karin Stephen, Univ. Coll. ; C. E. R. Stephenson, St. George's ; C. L. Stote, Cambridge and London ; R. Stuppel, Cardiff and Univ. Coll. ; F. J. Swinton-Esher, Birmingham ; H. Syed, Bombay and King's Coll. ; W. K. Targett, Guy's ; J. E. Teale, Leeds ; J. G. T. Thomas, Cambridge and St. Mary's ; A. R. Thompson, London ; O. L. Truscott, St. Thomas's ; C. I. Tuckett, Cambridge and St. Thomas's ; F. B. Turner, Cambridge and London ; Aimee A. L. Vaillant, Liverpool ; L. S. P. Wakeley, King's Coll. ; A. C. R. Walton, Birmingham ; Kathleen M. Ward, Liverpool ; N. Wassif, Assiut and Charing Cross ; R. Watson, Cambridge and Univ. Coll. ; T. C. S. Webb, Univ. Coll. ; W. N. Welinkar, Bombay and Middlesex ; Beatrice A. Wilkinson, King's Coll. ; L. S. Williams, Guy's ; A. A. Wilson, McGill and St. Mary's ; A. G. Wilson, Oxford and St. Thomas's ; C. S. Wise, St. Bart.'s ; and A. H. Wortman, Univ. Coll.

ROYAL COLLEGE OF SURGEONS OF EDINBURGH.—At recent dental examinations, out of 42 candidates entered, the following 16 have passed the Final Professional Examination and have been granted the diploma of L.D.S. R.C.S. Edin. :—

George C. Hodgson, Maria L. Burnet, Alexander G. L. Anderson, Francis Gibson, Bartholomew Hair, Henry G. Paterson, Ian Mc.G. Chisholm, James W. Galloway, Hugh N. Maclachlan, James A. Falconer, Edward L. Calder, Douglas J. Campbell, Henry McKenzie, Joseph L. Thomson, William Wallace, and James R. J. Cameron.

The following candidates passed in the under-mentioned subjects :—

Pathology.—John McAra, Neil I. Macmillan, Alexander S. Roberts, Bernard Silverston, Vernon L. Shearer, Andrew R. Ferguson, Gladys E. Munro, and Annie M. Kean.

Medicine.—Neil I. Macmillan, Alexander S. Roberts, Barryhill Moore, Bernard Silverston, Vernon L. Shearer, Andrew R. Ferguson, Gladys E. Munro, David Dunnet, and Edwin H. B. Gooch.

Surgery.—John McAra, Neil I. Macmillan, Bernard Silverston, Vernon L. Shearer, Andrew R. Ferguson, Gladys E. Munro, David Dunnet, Edwin H. B. Gooch, Annie M. Kean, and William G. Thow.

UNIVERSITY OF DUBLIN : SCHOOL OF PHYSIC, TRINITY COLLEGE.—At examinations held recently the following candidates were successful :—

FINAL MEDICAL EXAMINATION.

Part I., Materia Medica and Therapeutics ; Medical Jurisprudence and Hygiene ; Pathology and Bacteriology,—Gerald C. Dockeray (passed on high marks), Samuel Beggs, Ronald H. Bland, Daniel M. Brink, John R. Hanna, Harold E. Knott, and Ion W. Pigott.

In Completion.—George Q. Chance, Edward M. Gamble, J. Horwich, Evan K. Malone, and Claud E. G. Nunns.

ROYAL INSTITUTE OF PUBLIC HEALTH.—The Harben lectures for 1926 will be delivered in the lecture theatre of the Institute, 37, Russell-square, London, W.C. 1, on Nov. 15th, 18th, and 22nd, at 4 P.M., by Prof. W. W. C. Topley. The subject will be Quantitative Experiments in the Study of Infection and Resistance. All interested are invited to attend and no tickets of admission are required.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION.—On Thursday, Nov. 11th, at 5 P.M., at the rooms of the Medical Society of London, 11, Chandos-street, Cavendish-square, W., Mr. Arthur E. Giles will lecture on Emergencies in Gynæcological Practice. On the same day, at 1 P.M., Mr. Maurice Whiting will give a demonstration in Clinical Ophthalmology at the Royal London Ophthalmic Hospital, whilst on Nov. 12th, at 2 P.M., Mr. L. C. Rivett will give a clinical demonstration at the Chelsea Hospital. Both lecture and demonstrations are open to members of the medical profession without fee. The Royal Waterloo Hospital will hold a course in medicine, surgery, and gynæcology from Nov. 15th to Dec. 4th ; the fee will be £3 3*s*. From the same date there will be a one month's clinical course in Dermatology at the St. John's Hospital (fee £1 1*s*.) ; practical demonstrations in pathology are also being arranged (fee £4 4*s*.). From Nov. 22nd onwards a week's course in Diseases of the Rectum will be given at the St. Mark's Hospital, with instruction by demonstration, operation, and lecture. A late afternoon course in Neurology will begin on Nov. 22nd and continue for four weeks at the West End Hospital for Nervous Diseases, 73, Welbeck-street, W. A course for general practitioners will be provided for by the London Temperance Hospital from Nov. 29th to Dec. 11th. Courses in Obstetrics can now be arranged at the Queen Charlotte's Hospital and the City of London Maternity Hospital and practical courses in Anæsthetics can also be arranged. Copies of all syllabuses, of the General Course Programme, and of the *Post-Graduate Medical Journal* may be had from the Secretary of the Fellowship at 1, Wimpole-street, London, W. 1.

UNIVERSITY OF LONDON: *University College.*—The second of four lectures on Insulin by Dr. C. H. Best will be given at 5 P.M., on Nov. 10th at University College, Gower-street, W.C. 1, and the other two lectures will be at the same hour on the two following Wednesdays. Admission is free without ticket.

Birkbeck College.—A public lecture on University Education in the United States will be given by Mr. Edwin Deller, LL.D., Academic Registrar of the University, on Monday, Nov. 15th, at 5.30 P.M., in the theatre of the College. The chair will be taken by Sir William H. Beveridge, Vice-Chancellor of the University, and admission will be free without ticket. The address of the College is Bream's Buildings, Fetter-lane, London, E.C. 4.

Sir Cuthbert Wallace has been elected Dean of the Faculty of Medicine of the University of London for the period 1926–28.

HUNTERIAN SOCIETY.—A meeting of this society will be held at the Cutlers' Hall, Warwick-lane, London, E.C., on Monday, Nov. 15th, at 8.45 P.M., when there will be a discussion on Medicine and the Press. Among the speakers will be Sir Humphry Rolleston, Lord Riddell, Mr. J. M. Bulloch, LL.D. (editor of *The Graphic*), Dr. Graham Little, M.P., Mr. W. J. Evans (late editor of the *Evening News*), and Dr. Leonard Williams. Fellows may bring non-medical guests to this meeting.

PHARMACEUTICAL SOCIETY OF GREAT BRITAIN.—An evening meeting will be held at the society's house, 17, Bloomsbury-square, London, W.C. 1, on Tuesday, Nov. 9th, at 8 P.M., when Dr. J. H. Burn, director of the society's pharmacological laboratories, will read a paper on Some Methods of Biological Assay. Medical friends of members and associates will be welcome.

NATIONAL COUNCIL FOR MENTAL HYGIENE.—A public meeting will be held at the house of the Royal Society of Medicine, 1, Wimpole-street, London ,W. 1, on Wednesday, Nov. 17th, at 4.45 P.M., when Lord Southborough will take the chair and an address will be given by Mr. H. P. MacMillan, K.C., Chairman of the Royal Commission on Lunacy and Mental Disorder (1924-26). The third annual report of the Council may be had from the secretary at 118, Windsor House, Victoria-street, London, S.W. 1.

LECTURES ON ULTRA-VIOLET THERAPY.—A series of lectures on Ultra-Violet Therapy by Dr. Percy Hall, medical editor of the *British Journal of Actino-Therapy*, began at the Institute of Hygiene, 28, Portland-place, London, W. 1, on Nov. 3rd, and will continue on Wednesdays at 8 P.M. up to and including Dec. 8th. The subject of the next lecture on Nov. 10th is the Physics, Physiology, Biology, and Pathology of Light.

NATIONAL MILK CONFERENCE.—A national conference on Milk in Relation to Public Health will be held in the King George's Hall, Caroline-street, Great Russell-street, London, W.C., on Tuesday, Nov. 16th, from 10 A.M. Reports will be submitted by public authorities on the present conditions of the milk-suply; suggestions for its improvement will be considered. Mr. Neville Chamberlain, Minister of Health, who is President of the conference, will speak during the afternoon session; amongst other speakers during the day will be Miss Harriette Chick, D.Sc., Dr. W. G. Savage, and Prof. H. R. Kenwood. The fee for membership of the conference is one guinea and application should be made as soon as possible to the secretary, Miss J. E. Holland, at 3, Bedford-square, London, W.C. 1, from whom alone tickets may be obtained.

CONFERENCE ON MENTAL WELFARE.—Under the auspices of the Central Association for Mental Welfare a conference, postponed from May last, will be held in the Central Hall, Westminster, on Thursday, Dec. 2nd, and Friday, Dec. 3rd. The first session will be devoted to the Proper Care of Defectives Outside Institutions. Sir Leslie Scott, the President of the Association, will take the chair; Miss Ruth Darwin and Mr. J. Sandeman Allen, M.P., will read papers, and Mrs. Hume Pinsen will open a discussion. On Thursday afternoon Mr. H. P. Macmillan, K.C., Chairman of the Royal Commission on Lunacy (1924–26) will take the chair at a meeting devoted to Borderland Cases, when papers will be read by Lieut.-Colonel Edwin Goodall, M.D., and Dr. W. R. Kemlo Watson. The subject of the session on Friday morning will be the Training of Teachers for Special Schools. Dr. H. B. Brackenbury will take the chair and Lord Eustace Percy, President of the Board of Education, will give the opening address. At the afternoon session Sir Archibald Bodkin, Director of Public Prosecutions, will act as chairman, and papers on Encephalitis Lethargica and its After-effects will be read by Dr. A. F. Tredgold and Dr. F. C. Shrubsall. Tickets (price 5*s.*) for admission to all sessions of the conference, and advance copies of papers, may be had from Miss Evelyn Fox, 24, Buckingham Palace-road, London, S.W. 1.

ROYAL SOCIETY OF MEDICINE.—The annual dinner will be held at the Hotel Victoria, Northumberland-avenue, London, on Thursday, Nov. 18th, at 7.30 for 8 P.M., when it is hoped that the Prime Minister will be the guest of honour.

ROYAL DENTAL HOSPITAL OF LONDON.—The dinner of past and present students of the hospital is to be held at the Trocadero on Saturday, Nov. 20th, at 6.30 for 7 P.M., when Mr. W. H. Dolamore will preside. The medical staff of the hospital will be "at home" from 2 to 5 P.M. on the same day when cases of interest will be shown.

GRADUATES OF THE UNIVERSITY OF EDINBURGH.—The West Riding Association of Graduates of the University will hold its annual dinner at the Midland Hotel, Bradford, on Wednesday, Nov. 17th, at 7.15 P.M. Prof. Kemp Smith, Dean of the Faculty of Arts, is to be the guest of the evening. The dinner will be preceded by a general meeting at 6.30.

ROYAL NORTHERN HOSPITAL.—As we have already reported (THE LANCET, Oct. 16th, p. 834) a case of small-pox was admitted to this hospital on Oct. 7th. As soon as the diagnosis was made the patient and contacts were isolated, the staff was vaccinated, and visitors were prohibited except in cases of serious illness. Thanks to these precautions the only person to contract small-pox has been the patient who occupied the bed next to the original sufferer. In this case the disease has appeared in modified form, and the hospital is now, so to speak, out of quarantine.

ST. THOMAS'S HOSPITAL: ANNUAL DINNER OF OLD STUDENTS.—The Old Students' dinner of St. Thomas's Hospital was held on Friday last, Oct. 29th, at the Hotel Victoria, London, Dr. R. Percy Smith presiding. There was a large attendance, and among the guests present were the Director-General of the Naval Medical Service, Sir Joseph Chambers, the Director-General of the Army Medical Service, Sir Matthew Fell, Sir John Rose Bradford, Lord Riddell, the Hon. Sir Arthur Stanley, treasurer of the hospital, Dr. C. H. Bond, Dr. Ingleby Oddie, coroner for Westminster, and Sir Squire Sprigge.

The first proceeding, after the loyal toasts was the presentation to Mr. Crown of an engrossed testimonial and a cheque, the occasion being his retirement from office as janitor after serving the hospital for no less than 48 years. The episode gave the note to the speech in which the Chairman proceeded to propose the toast of The Hospital and Medical School, for in the course of an interesting review of past history he gave many instances of remarkable tenure of office in connexion with the institution. Sir Arthur Stanley replied and congratulated the audience on the success which the school was obtaining in work and play. He referred to the great generosity of Lord Riddell in connexion with the acquisition of land for additional building, so that no further encroachments will have to be made upon the quadrangles of the hospital as it was originally planned after the removal from London Bridge to Westminster Bridge. As an instance of what their splendid structure, however, cost the responsible authorities, he gave the cost of repainting the new corridor as £2000. He concluded by appealing in humorous terms for material gifts, or the money with which to buy them, the object being the furnishing of the new students' union. He mentioned easy-chairs and writing-tables and said that he would not despise ink-pots or even ash-trays. Sir Cuthbert Wallace, Dean of the school, also replied to the toast, and announced the winners of the entrance scholarships and prizes for 1926–27, and mentioned the fact that the hospital now held the football challenge cup. In recalling to the memory certain well-known men of the school who had died during the year he gave a vivid sketch of Dr. J. Maclean, who started as a veterinary surgeon, became veterinary expert to the New Zealand Government, and later decided to enter the medical profession. After qualification he was appointed surgeon to the British Seamen's Hospital at Constantinople, and at the outbreak of war joined the Armenian Red Cross. Having acquired considerable influence with the Levantines, he was for a time left free to discharge his medical duties, but at length was deported to a Turkish prison. Flatly declining to be imprisoned, he interviewed the Commandant, and remained free to exercise his medical knowledge for the benefit of his captors. On returning to England after release from captivity he was employed by the Foreign Office in the relief of our prisoners in the East, in the course of which he became solely responsible for the disbursement of many thousands of pounds. Recently he became medical officer to the London Fever Hospital, where his administrative services proved extremely valuable, and his loss to medicine, as the result of acute septicæmia, following a trivial injury to his finger, was really grave. The toast of the guests was proposed by Dr. J. S. Fairbairn and was replied to by Lord Riddell, who suggested that just as in the rule of the world the era of priests was succeeded by the era of kings, so the era of kings was now being succeeded by one of doctors. The health of the Chairman was proposed by Sir George Makins and was drunk with acclamation.

Messrs. H. K. Lewis and Co., Ltd., announce the following books for early publication: "Infections of the Hand," by L. R. Fifield; "A Shorter Surgery," by R. J. McNeill Love; "An Introduction to the Law and Tradition of Medical Practice," by W. Sanderson and E. B. A. Rayner; "Artificial Light Treatment of Children in Rickets, Anæmia, and Malnutrition," by K. M. L. Gamgee; "Ultra-Violet Rays in General Practice," by W. A. Troup; "X Ray Apparatus: Its Arrangement and Use," by P. K. Bowes; and "Popular Education in Public Health," by W. A. Daley and H. Viney.

THE LATE DR. W. H. JUDSON.—Dr. Wilfrid Hyde Judson, whose death at the age of 45 occurred at Brighton on Oct. 21st, was the youngest son of the late Mr. H. E. Judson, of Oldham, Lancashire. He graduated M.B. at the Victoria University of Manchester in 1907 and in the following year was President of the Manchester Medical Students' Debating Society. Before settling in practice at Brighton he acted as medical inspector of the Shipping Federation at Manchester, assistant medical officer in the venereal department at Charing Cross Hospital, and resident clinical assistant at the London Lock Hospital.

SOCIETY OF MEMBERS OF ROYAL COLLEGE OF SURGEONS OF ENGLAND.—This society is asking Members of the College to attend the annual general meeting of Fellows and Members to be held at the College on Thursday, Nov. 18th, at 3 P.M., and support the following resolution, to be proposed by Mr. Wansey Bayly and seconded by Dr. Redmond Roche:—

That this thirty-eighth annual meeting of Fellows and Members again affirms the desirability of admitting Members to direct representation upon the Council of the College, and respectfully requests the Council to take a postal vote of Fellows and Members on the general principle, as set out in this resolution.

It is stated that the by-laws of the College do not at present permit women to attend these meetings, though the right will presumably be granted them under the charter signed by the King in July last. The new President of the society is Dr. Ernest Ware, and the hon. secretary Dr. Sidney Lawrence, 106, Richmond Park-road, Bournemouth.

FUTURE OF THE VOLUNTARY HOSPITALS.—In reply to criticisms upon his speech at Coventry, which we briefly summarised last week (THE LANCET, Oct. 30th, p. 930), Mr. Neville Chamberlain explained in the *Times* that his policy is "wholly opposed to the creation of a State Medical Service." He is, however, anxious for "a closer coördination of the institutions existing in any given area by some body having general powers of guidance over hospital policy in that area." He adds that if the voluntary hospitals fail to take their part in such guidance "the body will undoubtedly be formed without them," an eventuality which he would "view with grave anxiety."—In his presidential address to the Incorporated Association of Hospital Officers last week the Hon. Sir Arthur Stanley advocated the formation of a hospitals association, "organised for service, protection, and progress." There already exist, he said, the Hospitals Department of the British Red Cross, the British Hospitals Association, and the Association of Hospital Officers, none of them representative of the hospitals or in a position to render complete service.

CONTINENTAL MEDICAL GRADUATES' ASSOCIATION. This association, known formerly as the Brussels University Medical Graduates' Association, held its annual dinner at the Langham Hotel on Oct. 28th, when Dr. H. Fielden Briggs, the President of the society, was supported by the Vice-President, Sir Thomas Carey-Evans. The toast of "The Association" was proposed by Sir Henry Jackson, and in response Dr. Briggs outlined the history of the Association and explained the objects—scientific and political—to be attained in the future. Under the former heading came the winter meetings at which eminent men would be asked to read papers, and summer congresses at various continental cities. Politically they would press for reciprocity of practice between this country and the European nations. Millions of English tourists and residents on the continent were unable to receive medical attention from their compatriots because they were prohibited from practising in those countries. Reform would imply an Act of Parliament to prohibit in this country the practice of medicine by unregistered persons. Mr. Hugh Edwards, M.P., signified his agreement with these remarks and promised to support such a Bill in Parliament if introduced by Sir Henry Jackson. Dr. Leonard Williams proposed the toast of "The Ladies" and Dr. Justina Wilson, in replying, contrasted the reception given to post-graduates on the continent to that at home. Sir Thomas Carey-Evans proposed "Kindred Societies," which was responded to by Mr. Mortimer Woolf, President of the Hunterian Society, and Mr. Ernest Young, President of the Chelsea Clinical Society. The concluding toast of "The President" was proposed facetiously by Dr. Campbell McClure.

WEST KENT MEDICO-CHIRURGICAL SOCIETY.—A meeting will be held at the Miller General Hospital, Greenwich, on Friday, Nov. 12th, at 8.45 P.M., when Mr. Harold Chapple will give an address on Abdominal Pain in Women.

ON Oct 1st the Sanatorium Wehrawald at Todtmoos in the southern part of the Black Forest was bought by the State Insurance Institute for four million marks and becomes from henceforth accessible only to insured patients. This sanatorium has had a long and distinguished career as an offshoot of Dr. Turban's sanatorium at Davos and now shares the fate of Dr. Walther's institution, better known in this country, in becoming part of the comprehensive system of insurance against tuberculosis which exists in Germany.

THE LATE DR. J. C. BRADSHAW.—Dr. James Charles Bradshaw, who died on Oct. 27th, in his sixty-ninth year, was well known in medical and Masonic circles in Liverpool. He studied medicine at the Royal College of Surgeons in Ireland and Queen's College, Birmingham, qualifying L.R.C.P. and L.R.C.S. Edin. in 1880, and taking the D.P.H. in 1889. He served as medical officer of health for the Sefton Rural District Council for 27 years and was a member of the old West Derby Board of Guardians. Formerly he was medical officer of health for the Brackley Rural District.

CHIROPODISTS IN CONFERENCE.—The first provincial conference of the Incorporated Society of Chiropodists was held in Manchester on Oct. 30th. The society was founded in 1913 "to support and protect the character, status and rights of chiropodists; to promote honourable professional demeanour, to repress malpractice, and to encourage scientific methods in the interests of the public and of legitimate practitioners." The society, which has now 350 members with branches in Manchester, Edinburgh, Yorkshire, and East Anglia, started the first free foot clinic for the poor in Europe, now known as the London Foot Hospital.

LEAGUE OF NATIONAL LIFE.—The first annual general meeting was held in the Caxton Hall, London, at 3 P.M. on Oct. 29th, Lord Fitzalan of Derwent being in the chair. The newly-elected President of the League, Dr. F. J. McCann, said that it was felt that contraception, or what is sometimes termed "birth control," was becoming a great national problem, indeed a problem of vital importance, and that accordingly the League was formed to influence public opinion along what they believed to be the correct lines, and to foster the perpetuation of family life which had always been one of the greatest traditions of the British race. He desired to make it clear at the outset that he did not approach the subject in any partisan spirit, his object being to seek the truth and to afford guidance to the many who are anxious to obtain it. His experience had led him to believe that the practice of contraception was evil and should be condemned because it was physically harmful to the female. Some of the methods of contraception were physically harmful to both sexes, but all known methods were in some degree harmful to the female. Physiological and clinical observations could be adduced to sustain the conclusion that the secretions of the male were absorbed by the uterus. It followed that any method of contraception which prevented or hindered this absorption deprived the female of far-reaching benefit to her bodily metabolism. Various contraceptive devices brought other dangers in their trail from infection, which was a real danger. Contraception could not be supported on medical grounds; it interfered with the whole physiological value of the sexual act, and its effects were injurious to the individual. Dr. Halliday Sutherland said that the League had been formed to combat the greatest and most insidious danger now confronting the nation and Empire. Birth prevention was race-suicide, and the suicide of a nation required less resolution than the suicide of an individual. The various fallacies of birth prevention would be exposed by experts—ethical, medical, statistical, and sociological—each writing or speaking in his own sphere. That was the immediate policy of the League. Dr. Letitia Fairfield said that perhaps the chief difficulty in the propaganda work of the League would be the fact that birth control was advocated as a panacea for every conceivable social evil. Those who undertook to oppose it are made to appear as reactionary. Members must be prepared to take up the arduous duty of disproving the case point by point, and this obviously was no light task. Experts were wanted to sit on the legal, economic, ethical, and medical subcommittees and hammer out the technicalities for the case against contraception in the closest detail. Writers—especially those with a gift for popular exposition—were wanted to shape reports into a form suitable for the public. Speakers were perhaps even more urgently required. The danger-point at the moment was the infant welfare clinic, and Dr. Fairfield described the special precautions which should be adopted to counter this form of attack.

COLLEGE OF PESTOLOGY.—The annual dinner and presentation of the Maxwell-Lefroy gold medal will take place at the Hotel Cecil on Thursday, Nov. 11th, at 7 for 7.30 P.M. Lt.-Col. Cuthbert James, M.P., will take the chair.

PRINCESS MARY AT STAMFORD INFIRMARY.—On Saturday Princess Mary opened a new wing, comprising maternity and children's wards, which have been erected as a war memorial at a cost of £11,000.

WEMBLEY HOSPITAL.—Sir J. R. Bradford, President of the Royal College of Physicians, on Saturday laid the foundation-stone of a hospital for Wembley. The cost has been found to be so much greater than was anticipated, partly on account of the coal stoppage, that further building operations are to be suspended until the dispute is settled.

SCARLET FEVER IN A LANCASHIRE INSTITUTION.—It was reported on Oct. 21st to the West Lancashire Rural District Council that a serious epidemic of scarlet fever had broken out at the School for Mental Deficients at Aughton, near Ormskirk, where 54 out of 107 inmates have been attacked. The Ministry of Health has asked for a special report. The medical officer states that he cannot trace the source of the infection.

HOSPITAL PROVISION FOR THE KENT COALFIELD.—The committee of governors of Dover Hospital have appointed a building committee to consider the best means of providing for the situation that is expected to arise from the coming development of the East Kent coalfields. The main subject for settlement is whether the hospital should be extended at an estimated cost of £15,000, or moved to another part of the town at a probable cost of £50,000. It is desired to extend the number of beds from 44 to 70.

BELFAST UNIVERSITY SERVICE CLUB.—The eighth annual dinner of this club will be held at 8 P.M. on Thursday, Nov. 11th, in Thompson's Restaurant, Donegall-place, Belfast. The President (Dr. J. S. Morrow, late Major, R.A.M.C.) will preside, and His Grace the Duke of Abercorn, V.-P., Governor of Northern Ireland, has signified his acceptance of the invitation to attend. The cost of the dinner will be 12*s.* 6*d.* (exclusive of wines) and those past and present Queensmen who wish to attend are requested to signify their intention of attending to the hon. secretaries, Dr. Robin Hall, 35, University-road, Belfast, or Major R. McCreary, *M.C.*, 15, Donegall Park-avenue, Belfast. On the same day, at 11 A.M., a wreath will be placed at the War Memorial in the University grounds in memory of fallen Queensmen, when it is hoped that all past and present Queensmen who can will attend.

ROYAL VICTORIA HOSPITAL, BELFAST.—The present session was opened on Oct. 19th, when an address was delivered by Mr. S. T. Irwin, F.R.C.S.I., who traced the history of the hospital from its origin in the old General Hospital in Frederick-street, which was opened in 1817. Various additions, he said, had been made from time to time, but the rapid growth of Belfast had made the hospital quite inadequate to the needs of the city, and in 1923 the present buildings had been erected, largely owing to the exertions of Lady Pirrie and the late Lord Pirrie. The hospital was built on the plenum system and represented the latest modern ideas. The work continued to grow rapidly; the staff had increased from 17 to 37, the residents from 4 to 14, and the nursing staff from 60 to 150. The number of patients, intern and extern, had been doubled. The recent extensions which were now complete, had raised the number of beds to 436, and all departments had received additions and more adequate equipment. The newly established dental department had had about 10,000 cases in the past year.

INSPECTION OF SCHOOL-CHILDREN IN IRELAND.—Mr. E. F. Stephenson, F.R.C.S.I., chief medical officer of the Department of Local Government and Public Health, gave an interview last week in which he described the inspection of school-children shortly to be undertaken in the Irish Free State. The local authorities, he said, would, in the first instance, prepare draft schemes detailing the number of National schools and the number of children. When appointed, the county medical officers of health would make preliminary surveys of the schools to get a working knowledge of the general physique and the standard which children of approximately the same age have attained in the different schools. The regulations provided for a general inspection of children and for inspection of children at specified age-periods. Each child would be first given a general examination by a doctor and then those who suffered from any particular defect would be treated. It was intended to utilise the existing hospitals as treatment centres and to make use of the services of nurses employed by district nursing associations, thus encouraging voluntary effort. In several cases special clinics, especially dental clinics, would be required. It was intended, Mr. Stephenson said, to coördinate the scheme with maternity and child welfare work.

UNIVERSITY OF DURHAM COLLEGE OF MEDICINE.—The first of a series of three lectures on the History of Medicine will be given in the College, Newcastle-upon-Tyne, by Dr. Charles Singer, on Nov. 19th, at 4.45 P.M.; all medical practitioners in the neighbourhood are invited.

Sir Thomas Oliver has been elected President of the College of Medicine, University of Durham, in place of Sir David Drummond, who has resigned, after serving the College in this capacity for eight years.

ROYAL SOCIETY OF EDINBURGH.—At the annual statutory meeting of this society held on Oct. 25th, Prof. Thomas Bryce, F.R.S., was elected a Vice-President. Amongst the councillors appointed were Lieut.-Colonel A. G. McKendrick, Prof. David Waterston, and Dr. Logan Turner.

SAVE THE CHILDREN FUND.—A concert party known as the Magpies is giving an entertainment at King George's Hall, off Tottenham Court-road, London, on the evening of Friday, Nov. 12th, in aid of the fund's first open-air residential school for delicate London children, established at St. Peter's, near Broadstairs. Tickets, from 1*s.* 3*d.* to 5*s.*, may be had from the concert secretary, 26, Gordon-street, London, W.C. 1.

DEFECTIVE BIRMINGHAM CHILDREN.—An extension of the Baskerville School for Physically Defective Children at Harborne has been opened by the Duchess of Atholl, M.P., Parliamentary Secretary to the Board of Education. The original intention of providing a school for crippled children was diverted into one for succouring children suffering from heart trouble. There has thus been provided what the Duchess described as "a new type in the provision of schools for defective children." The alteration was determined upon when it was found that the main source of supply was children suffering from the effects, especially upon the heart, of rheumatic affections.

SURGICAL INSTRUMENT MANUFACTURERS' ASSOCIATION.—The annual dinner was held at the Holborn Restaurant on Oct. 29th, Mr. G. W. Mayer presiding. The principal guests were Mr. Irwin Moore and Mr. L. Ferris-Scott. Mr. Patrick C. Maw, in proposing the toast of the association, said British surgical instruments were the product of skilled workmen, who took pride in turning out the best. The Chairman, in replying, said they had to try to induce surgeons and institutions throughout the country to order British goods. Mr. Irwin Moore, in replying to the toast of "The Guests," which was ably proposed by Colonel A. Young, said that he and all surgeons owed a deep debt of gratitude to the British surgical instrument makers, who were ever ready and willing to assist them. It was a well-known fact that no surgical instruments in the world could compete or compare in quality or efficiency with the British surgical instruments.

Medical Diary.

Information to be included in this column should reach us in proper form on Tuesday, and cannot appear if it reaches us later than the first post on Wednesday morning.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

MONDAY, Nov. 8th.—5 P.M., WAR. Colonel J. W. West, R.A.M.C.: Peace-time Military Surgery.

TUESDAY.—5 P.M., THERAPEUTICS AND PHARMACOLOGY. Discussion on the Biological Standardisation of Remedies, to be opened by Dr. H. H. Dale. 8.30 P.M., PSYCHIATRY. Prof. Geo. M. Robertson: An Analysis of the Decrease in the number of Deaths from General Paralysis in England and Wales.

WEDNESDAY.—5.30 P.M., SURGERY: SUBSECTION OF PROCTOLOGY (specimens at 4 P.M.). Presidential address: Mr. J. P. Lockhart-Mummery: Non-malignant Tumours of the Colon and Rectum. A discussion will follow. There will be a collection of specimens of non-malignant tumours of the colon and rectum, excluding diverticulitis, from London and provincial hospitals.

THURSDAY.—8.30 P.M., NEUROLOGY. Clinical meeting at the West End Hospital for Nervous Diseases.

FRIDAY.—5.30 P.M., CLINICAL. (Cases at 5 P.M.) Mr. P. Turner: A Case of Pseudo-Hermaphroditism. Dr. Worster-Drought: Charcot's Arthropathy of Wrist. Mr. W. E. Tanner: A Case of Elevation of the Scapula. Mr. E. Pearce-Gould: A Case for Diagnosis. Dr. Parsons-Smith: A Case of Pleural Effusion of Doubtful Origin. Mr. F. D. Saner: Symptomless Abdominal Tumour for Diagnosis. Mr. N. L. Eckhoff: A Case of Diaphyseal Aclasia. Dr. Dorothy Hare: Splenomegaly and Cirrhosis wih Facial Telangiectases.

Mr. E. G. Slesinger: Carcinoma of the Thyroid. Cases will also be shown by Prof. C. A. Pannett and Mr. H. W. Carson. 8.30 P.M., OPHTHALMOLOGY. (Cases at 8 P.M.) Discussion on Macula Colobomata, to be opened by Mr. Malcolm L. Hepburn. Drawings illustrating the condition will be shown.

MEDICAL SOCIETY OF LONDON, 11, Chandos-street, Cavendish-square, W.
MONDAY, Nov. 8th.—8.30 P.M., Discussion on Sternal Pain, to be introduced by Dr. John Parkinson, followed by Mr. A. J. Walton.

BIOCHEMICAL SOCIETY.
MONDAY, Nov. 8th.—5 P.M. (In the Chemical Department, St. Thomas's Hospital Medical School.) *Communications.* J. Needham (introduced by D. M. Needham): The Rhythm of Chemical Differentiation in Avian Embryos. E. M. Goldblatt: Some Observations on Acidosis and Alkalosis. W. J. Griffiths and H. MacLean: The Part Played by Regurgitation in Gastric Digestion. J. Lowndes: Estimation of Cystine in the Modified Van Slyke Method of Analysis of Proteins. R. H. A. Plimmer: Changes in the Amino Acids in the Proteins of the Hen's Egg during Development. J. L. Rosedale: The Amino Acids of Flesh. H. W. Dudley, O. Rosenheim, and W. W. Starling: Spermidine, a Hitherto Undescribed Base Occurring in Animal Tissues. W. J. N. Burch: Hydrolysis of Phosphoric Esters. R. H. A. Plimmer and W. J. N. Burch: The Action of Ethyl Metaphosphate on Alcohols, Ammonia, and Some Amino Compounds. J. G. Davis and W. K. Slater: Aerobic and Anaerobic Metabolism of the Cockroach.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

ROYAL COLLEGE OF PHYSICIANS, Pall Mall East, S.W.
TUESDAY, Nov. 9th.—5 P.M., Dr. Arthur Shadwell: Medicine in Ancient Assyria. (First Fitz-Patrick Lecture.)
THURSDAY.—5 P.M. (Second Fitz-Patrick Lecture.)

ROYAL COLLEGE OF SURGEONS OF ENGLAND, Lincoln's Inn-fields, W.C.
THURSDAY, Nov. 11th.—5 P.M., Prof. E. W. Hey Groves: Reconstructive Surgery of the Hip Joint. (Bradshaw Lecture.)

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, W.
MONDAY, Nov. 8th, to SATURDAY, Nov. 13th.—FELLOWSHIP OF MEDICINE. Special lecture at the Medical Society of London, 11, Chandos-street, Cavendish-square, W. Thurs., Nov. 11th, at 5 P.M., Mr. A. E. Giles: Emergencies in Gynæcological Practice. Free to members of the medical profession.—ROYAL LONDON OPHTHALMIC HOSPITAL, City-road. Thurs., Nov. 11th, at 1 P.M., Mr. Maurice Whiting: Clinical Demonstration. Free to members of the medical profession.—CHELSEA HOSPITAL FOR WOMEN, Arthur-street, S.W. Fri., Nov. 12th, at 2 P.M., Mr. L. C. Rivett: Special Demonstration. Free to members of the medical profession.—HAMPSTEAD GENERAL HOSPITAL, Haverstock-hill, N.W. Practitioners' course in medicine, surgery, and the specialties, 4.30 to 6 P.M. Clinical demonstrations and short lectures. Further information from the Secretary of the Fellowship of Medicine.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.
MONDAY, Nov. 8th.—2 P.M., Medical Cases in the Wards. 2.30 P.M. to 5 P.M., Medical, Surgical, and Gynæcological Clinics. Operations.
TUESDAY.—2.30 P.M. to 5 P.M., Medical, Surgical, Throat, Nose, and Ear Clinics. Operations.
WEDNESDAY.—2.30 P.M. to 5 P.M., Medical Skin and Eye Clinics. Operations.
THURSDAY.—2.30 P.M. to 5 P.M., Medical, Surgical, and Ear, Nose, and Throat Clinics. Operations.
FRIDAY.—2.30 P.M. to 5 P.M., Surgical, Medical, and Children's Diseases Clinics. Operations.
On Monday, Nov. 8th, and Friday, Nov. 12th, at 2.30 P.M., there will be Special Demonstrations of Medical and Surgical Cases by Dr. J. B. Alexander and Mr. E. Gillespie respectively.

WEST LONDON POST-GRADUATE COLLEGE, West London Hospital, Hammersmith.
MONDAY, Nov. 8th.—11 A.M., Mr. Tyrrell Gray: Surgical Wards. 12 noon, Mr. Simmonds: Fractures and Applied Anatomy. 2 P.M., Dr. Scott Pinchin: Medical Out-patients.
TUESDAY.—11 A.M., Mr. Endean: Venereal Diseases. 12 noon, Dr. Burrell: Chest Cases. 2 P.M., Mr. Banks-Davis: Throat, Nose, and Ear Dept.
WEDNESDAY.—10.30 A.M., Dr. Burnford: Medical Wards. 2 P.M., Dr. Owen: Medical Out-patients. 2 P.M., Mr. Gibb: Eye Dept.
THURSDAY.—11 A.M., Resident Assistant Surgeon: Surgical Wards. 2 P.M., Mr. MacDonald: Genito-Urinary Department. 2 P.M., Mr. Donald Armour: Operations.
FRIDAY.—10 A.M., Sir Henry Simson: Gynæcological Operations. 12.15 P.M., Dr. Pritchard: Modern Methods in Medicine. 2 P.M., Mr. Sinclair: Surgical Out-patients.
SATURDAY.—9.30 P.M., Dr. Burnford: Bacterial Therapy Department. 10 A.M., Dr. Saunders: Medical Diseases of Children. 10 A.M., Mr. Banks Davis: Throat, Nose, and Ear Operations.
Daily, 10 A.M. to 5 P.M., Operations, Medical, Surgical, and Special Out-patients Departments, Operations. Saturdays, 10 A.M. to 1 P.M.

UNIVERSITY COLLEGE, Gower-street, W.C.
WEDNESDAY, Nov. 3rd.—5 P.M., Dr. C. H. Best: Insulin. (First of four advanced lectures in Pnysiology.)

POST-GRADUATE HOSTEL, Imperial Hotel, Russell-square, W.C.
TUESDAY, Nov. 9th.—9 P.M., Dr. S. Wright: The Output of the Heart in Health and Disease.
THURSDAY.—9 P.M., Mr. H. A. Harris: Epiphyses. Dinner, 8 P.M., 5*s*.

HOSPITAL FOR SICK CHILDREN, Great Ormond-street.
THURSDAY, Nov. 11th.—4 P.M., Mr. Barrington-Ward: Common Congenital Malformations.

NATIONAL HOSPITAL, Queen-square, Bloomsbury, W.C.
MONDAY, Nov. 8th.—2 P.M., Dr. Hinds Howell: Out-patient Clinic. 3.30 P.M., Mr. Williamson-Noble: Papillœdema.
TUESDAY.—2 P.M., Dr. Walshe: Out-patient Clinic. 3.30 P.M., Dr. Risien Russell: Incoördination.
THURSDAY.—2 P.M., Dr. Kinnier Wilson: Out-patient Clinic. 3.30 P.M., Mr. Just: Methods of Testing the Eighth Nerve (in Out-patient Department).
FRIDAY.—2 P.M., Dr. Adie: Out-patient Clinic. 3.30 P.M., Mr. Perkins: The Treatment of Poliomyelitis.

LONDON SCHOOL OF DERMATOLOGY, St. John's Hospital, 49, Leicester-square, W.C.
TUESDAY, Nov. 9th.—5 P.M., Dr. H. MacCormac: Diseases Due to Animal Parasites.
THURSDAY.—5 P.M., Dr. A. C. Roxburgh: Eruptions Due to Physical Causes.

MANCHESTER ROYAL INFIRMARY POST-GRADUATE COURSE.
TUESDAY, Nov. 9th.—4.15 P.M., Dr. W. E. Gye: An Outline of the Knowledge gained by the Experimental Study of Cancer. (Lloyd Roberts Lecture.)
FRIDAY.—4.15 P.M., Mr. J. F. Dobson: Oral Cancer.

ST. MARGARET'S HOSPITAL FOR WOMEN, Acomb-street, Whitworth Park, Manchester.
WEDNESDAY, Nov. 10th.—4 P.M., Mr. A. C. Magian: Insufflation of the Fallopian Tubes in Sterility and X Rays in the Diagnosis of Pregnancy.

UNIVERSITY OF SHEFFIELD POST-GRADUATE CLINICS.
FRIDAY, Nov. 12th.—3.30 P.M., at the Royal Infirmary: Mr. Cuff: Surgical Clinical Cases.

ANCOATS HOSPITAL POST-GRADUATE COURSE.
THURSDAY, Nov. 11th.—4.15 P.M., Mr. F. Holt Diggle: Tonsillectomy.

JAMES MACKENZIE INSTITUTE FOR CLINICAL RESEARCH, St. Andrews.
TUESDAY, Nov. 9th.—4 P.M., Prof. Ashley Mackintosh: The Treatment of Arteriosclerosis. Discussion to be opened by Dr. Bryson.

ROYAL INSTITUTE OF PUBLIC HEALTH, 37, Russell-square, W.C.
WEDNESDAY, Nov. 10th.—4 P.M., Prof. Winifred Cullis: Industrial Psychology Applied to the Home.

Appointments.

DAVIES, IVOR HUGHES, M.B., Ch.B. Liverp., has been appointed District Medical Officer and Vaccination Officer for the Unchaled District of Corwen Union.

NELIS, IRIS PHILIPPINE, L.R.C.P. & S.I., Medical Officer of Health to the Mold Urban Council.

Vacancies.

For further information refer to the advertisement columns.

Bath, Royal United Hospital.—H.P. and H.S. At rate of £120 and £100 respectively.
Birmingham and Midland Homœopathic Hospital and Dispensary.—H.S. £150.
Birmingham, Queen's Hospital.—Hon. Dental Surgeon. Also Hon. S. to Ear, Nose, and Throat Dept.
Birmingham Union, Selly Oak Hospital.—Res. Jun. Asst. M.O. At rate of £200.
Calcutta Presidency College.—Prof. of Physiology. Rs.650 per month.
Cancer Hospital, Fulham-road, S.W.—Jun. Radiologist. £500.
Carlisle Non-Provident Dispensary.—Res. M.O. £300.
Cheshire County Council.—Two Dist. Tub. O.'s. Each £600.
City of London Maternity Hospital, City-road, E.C.—Asst. Res. M.O. At rate of £80.
Cosford Union.—Dist. M.O. for Kersey Relief District. £44 3*s*. 8*d*.
Eastern Dispensary, Leman-street, E.—Gynæcologist.
Elizabeth Garrett Anderson Hospital, Euston-road, N.W.—H.P. Obstet. Asst. and two H.S.'s. Each at rate of £50. Also Clin. Assts.
Federated Malay States Medical Dept.—Radiologist. £700.
Freemason's Hospital and Nursing Home, 237, Fulham-road, Chelsea, S.W.—Res. M.O. At rate of £250.
Hospital for Consumption and Diseases of the Chest, Brompton, S.W.—Asst. P.
Hull Royal Infirmary.—Hon. Phys.

London, Female Lock Hospital, 283, Harrow-road, W.—Hon. Obstet. S.
London Temperance Hospital, Hampstead-road, N.W.—Hon. P.
Manchester, Baguley Sanatorium.—Asst. M.O. £350.
Manchester Royal Infirmary.—Sen. Pathological Registrar. £100. Also Surgical Tutor. £30. Also Hon. Neurological Surg.
Manchester, Victoria Memorial Jewish Hospital.—Jun. H.S. At rate of £120.
Manor House Hospital, Golders Green, N.W.—Asst. S. £750.
Middleton-in-Wharfedale Sanatorium.—Sen. Asst. M.O. £600.
Miller General Hospital for South-East London, Greenwich-road, S.E.—Asst. P. and two Asst. S.'s.
Northampton General Hospital.—Hon. S.
Oxford, Radcliffe Infirmary and County Hospital.—Hon. Asst. S. and Hon. Asst. Phys. to Electro-therapeutic Dept.
Portsmouth, St. Mary's Infirmary, &c.—Third Asst. Res. M.O. £250.
Royal College of Physicians, Pall Mall East.—Milroy Lecturer for 1928.
Royal Northern Hospital, Holloway, N.—M.O. to Out-patients. At rate of £125. Also H.S. At rate of £70.
St. George's Hospital, S.W.—Temp. Obstet. Reg. £40.
St. Mary's Hospital for Women and Children, Plaistow, E.—Res. M.O. and Asst. Res. M.O. At rate of £175 and £130 respectively.
Shanghai Municipal Council, Public Health Dept.—Asst. Pathologist. Tls.600 per mensem.
Sheffield, Winter-street Hospital.—Res. Tuberculosis M.O. £350.
Shrewsbury, Salop Mental Hospital.—Second Asst. M.O. £500.
South Uist Parish and Northern Division.—M.O. and Pub. Vaccinator. £620.
Throat Hospital, Golden-square, W.—Sec. Supt. £500. Also H.S. At rate of £100.
Truro, Royal Cornwall Infirmary.—H.S. £170.
West London Hospital, Hammersmith, W.—Phys.

The Chief Inspector of Factories announces the following vacant appointments for Certifying Factory Surgeons: Dulverton, Somerset; St. Andrews, Fifeshire; Tiverton, Devon; and Richmond, Surrey.

Births, Marriages, and Deaths.

BIRTHS.

BUCHANAN.—On Oct. 24th, at Dale House, Shaw, the wife of Dr. Buchanan, of a son.
ENNION.—On Oct. 26th, at Harlech House, Burwell, Cambs., the wife of E. A. R. Ennion, M.R.C.S., L.R.C.P., of a daughter.
MOORE.—On Oct. 25th, 1926, at Malta, the wife of Surgeon-Commander Maurice Sydney Moore, M.D., D.P.H., R.N., of a son.

MARRIAGES.

HURRELL—LIMONT.—On Oct. 28th, at St. Luke's, West Norwood, George Hurrell, M.D., B.S., D.P.H. (Dunelm), elder son of Mr. and Mrs. G. Hurrell, of North Shields, to Margaret Evangeline, second daughter of the late James Limont, M.R.C.P., of Newcastle-upon-Tyne, and Mrs. Limont, of West Norwood.
MILLER—BAILEY.—On Oct. 30th, Thomas Duff Miller, M.D., F.R.F.P. & S. Glasg., to Trixie, only daughter of Mr. and Mrs. C. W. Bailey, of Battersea Park.

DEATHS.

BARENDT.—On Oct. 28th, suddenly, Frank H. Barendt, M.D. Lond., F.R.C.S. Eng., of Rodney-street, Liverpool.
CHURTON.—On Oct. 30th, at Cromer-road, Leeds, Thomas Churton, M.D., in his 88th year.
CROWDY.—On Oct. 26th, at South Grove, Highgate, Frederic Hamilton Crowdy, M.D., in his 75th year.
FLEETWOOD.—On Oct. 27th, at his residence, Tye House, Hadleigh, Suffolk, William Hardy Fleetwood, M.R.C.S., L.R.C.P.
MACKNESS.—On Oct. 31st, at Auchlean, Broughty Ferry, George Owen Carr Mackness, M.D.
RUDGE.—On Oct. 24th, at Whiteladies-road, Bristol, Charles King Rudge, M.R.C.S., L.R.C.P., aged 80.
SMITH-WYNNE.—On Oct. 26th, at Amersham, Bucks, suddenly, of heart failure, Graham Shaw Arnold Smith-Wynne, M.R.C.S., L.R.C.P.
WARNER.—On Oct. 26th, at "Whitbourne," Warlingham, Surrey, Francis Warner, M.D., F.R.C.P., F.R.C.S., in his 80th year.
WILLES.—On Oct. 30th, at Queen Adelaide-road, Penge, S.E., Joseph Willes, M.R.C.S., L.S.A. (Guy's), aged 88.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

NEWCASTLE-UPON-TYNE THROAT, NOSE, AND EAR HOSPITAL.—The Duchess of Northumberland has opened a new wing in which modern operating theatres have been provided and the internal arrangements greatly improved. The work has drained the resources of the hospital, which has never before appealed for money, although it has been in existence for nearly 50 years.

Notes, Comments, and Abstracts.

MENTAL HOSPITALS

AND THEIR RELATION TO GENERAL AND TO OTHER SPECIAL HOSPITALS.*

BY G. F. BARHAM, M.D. CAMB.,
MEDICAL SUPT., LONDON COUNTY MENTAL HOSPITAL, CLAYBURY.

THE position which mental hospitals shall occupy in any comprehensive scheme of hospital organisation has become a question of national importance. It is only necessary to point to the high proportion of the population affected, to the magnitude of the problem of insanity, with its inseparable legal complications, and to the urgent need for team-work for research into the causes of mental disease, the discovery of new methods of treatment, and for investigating the whole question from the standpoint of preventive medicine. Mental hospitals cannot cope single-handed with these problems, for they mainly deal with the more advanced forms of disease. But neither can any other organisation which does not bring them into line in a uniform attack. The reason for insisting on this point is made clear by examining the trend of certain movements for reforming the lunacy law, and our methods of dealing with early forms of mental disorder. The pivot of these movements is the unsatisfactory working of the law, especially in its application to incipient and early cases, and the backward state of our knowledge of mental disease. They have already helped to bring about much improvement in organisation and education, and the Royal Commission which they helped to promote holds promise of many desirable reforms.

The Unity of Mental Disease.

There are, however, aspects of the propaganda employed which demand serious consideration. In the eagerness to secure freedom to treat early cases in clinics and nursing homes, and to avoid certification, the unity of mental disease tends to be overlooked. Mental hospitals have, often most unjustly, been maligned and suggestions have been made, the application of which would lead to the widening of the gulf of morbid sentimentality, which stands between these hospitals and the community, and tends moreover, to separate them from other branches of medicine. There is, in fact, a danger that the present tendency will, intentionally or otherwise, accentuate the isolation of mental hospitals, and that the more pronounced forms of disease with which these hospitals deal will remain beyond the borderland in a class marked off from all other forms of disease, thus perpetuating the stigma which ignorant prejudice attaches to them, and that the clock will be set back upon the time when a more enlightened community attains some understanding of the meaning and nature of disordered function of the brain and mind. The treatment of mental disease was formerly carried on without any active or close association with general medicine. For more than a generation, however, mental institutions have been progressively reforming themselves from within, but progress has been slow and there has been but little constructive help from outside. Not only was psychiatry neglected and badly taught in medical schools, but there was little tendency on the part of the medical centres, of universities, until quite recent times, to take any active part in solving the problems inherent in disease of the mind, or in grappling with the urgent need for teaching psychological medicine, or providing facilities for treating early cases.

Hospitalisation of Asylums.

The adoption of the title "mental hospital" in place of asylum represented more than a mere change of nomenclature. It marked at least one milestone on the difficult road taken by those who sought to change the whole character of these institutions. Hospitalisation of asylums means, in effect, not only the acquirement of hospital equipment and the employment of the discoveries of modern scientific medicine in the investigation and treatment of mental disease, but also an endeavour to secure the coöperation of specialists in other branches of medicine, concentration on organised research work, and the efficient teaching of psychiatry. Associated with this change, moreover, is the establishment of training schools with qualified teachers for mental nurses, and an endeavour to enlist the help and interest of general trained nurses in this highly specialised branch of nursing.

The old conception of the asylum is one that is rapidly passing. Mental hospitals are no longer mysterious closed institutions with conspicuously locked doors and blocked

* An appendix to the Seventh Annual Report on the Voluntary Hospitals in Great Britain, Red Cross Joint Council, 19, Berkeley-street, London, W. 1. 1s. 6d. post free.

windows, nor are they now essentially places of detention. Discharge of a patient is in most cases an easy matter. The hospital is freely open to public inspection, hospital visitors are encouraged, and convalescence and recovery are the first objects of treatment, and there are wide facilities for the freedom and occupation of the patients. It is, of course, essential that incipient and early cases of mental disorder should not be associated with more pronounced insanity, and to this end the widest facilities are required for their treatment in clinics, and for a really effective classification when it becomes necessary to place them in mental hospitals. But in all the propaganda for separate treatment outside mental hospitals, how frequently the unity of mental disease is overlooked. A patient, for example, suitable for treatment in a clinic or nursing home in one phase of the disease, may be quite unacceptable in another. The extreme variableness of the manifestations of any one form of disorder renders the closest coöperation and the easiest facilities for interchange between clinics and mental hospitals essential. But this end will not be gained by any measure which does not break down the general prejudice against the latter institutions, nor helps to remove the suspicion and dread which so often is attached to them.

A New Conception of Mental Hospital.

It is one of my objects to show that the closest coöperation between general hospitals, clinics, and mental hospitals is essential not only for the efficient treatment of mental disease, but also to coördinate research and to place the mental hospitals in a position to carry on their proper work, not isolated from, but in association with, other hospitals. The way is prepared for a new era in the treatment of mental disease, and it is contended that the open coöperation of the medical profession in this treatment will more effectually than by any other means restore public confidence and remove that dread of asylums which has done so much harm in fostering the growth of chronic insanity. Recognition of the importance of psychological medicine, not alone in the treatment of actual mental disease, is daily becoming more widespread. The evidence before the Royal Commission abundantly testifies to the general desire for liberty to treat mental cases in clinics, general hospitals, and private homes, as well as in mental hospitals. The opening of the Maudsley Hospital marked an important advance. There is scope for many more similar hospitals, but there is perhaps still greater need at the present time for psychiatric and neurological clinics at all general hospitals, especially those attached to schools of medicine. The provision of facilities for in-patient treatment of early mental cases is a question of public interest, and is required for teaching and research. Even a liberal provision of clinics, however, must leave untouched the major problem of the treatment of the great mass of certifiable cases as well as of those early cases for which the clinics would be unsuitable. Moreover, the situation of the modernised mental hospital and the opportunities it affords are more adaptable for the care and treatment of the majority of mental cases, certified or voluntary, a very large proportion of which will always require the care of a rate- or State-supported hospital under State supervision.

Linking up of Hospital Units.

The question at issue concerns the part mental hospitals shall play in the linking up of hospital units in the future organisation of an efficient medical service. No sequestered position beyond an ill-defined borderland will suffice to remove the present disabilities under which these institutions labour. Mental hospitals must take an equal place with other special hospitals. Their participation in the general progress of medicine can alone be achieved by measures which, while comprising a single organisation for the mental welfare of the community, make adequate provision for the treatment of the physical as well as the psychological aspect of mental disease and enable mental hospitals to work in coöperation with other hospitals. The realisation of this objective requires :—

1. The formation of homogeneous units within a scheme of hospital organisation to include the clinic of a general hospital, a reception hospital, and a mental hospital.
2. The development of existing institutions which must of necessity function in any comprehensive scheme dealing with mental disease, and the promotion of coöperation between them and other hospital units by means of visiting staff and easy facilities for interchange and for out-patient treatment.
3. The utmost possible freedom to treat mental cases in clinics and private houses and the adoption of the voluntary system on the widest basis compatible with security.
4. The education of public opinion in regard to mental disorders and the need for early treatment ; and the removal, as far as possible, of all semblance of compulsion and detention.

If this position is accepted, the mental hospital of the future will take its place as one unit of a special department in an organised scheme for hospital treatment subserving defined areas, and mental patients will participate in those benefits and humane considerations open to all free members of the community. Such a comprehensive scheme will no doubt take much time and energy in realisation.

Affiliation with General Hospitals.

In the meantime mental hospitals stand in urgent need of assistance through coöperation, and an intermediate step in the direction of a working affiliation with general hospitals—already in force in a few instances and under contemplation in others—would be a most desirable preparatory move towards the more comprehensive organisation. Affiliation implies a voluntary working association between a mental hospital and the nearest general hospital, where possible attached to a school of medicine, for the purpose of :

1. Increasing the means for the treatment of mental disease.
2. Organising research work.
3. Developing the teaching of psychological medicine.
4. Increasing the facilities for training nurses.

By affiliation mental hospitals would acquire the services of a consultant staff of specialists, and the association of the mental hospital staff with doctors specialising in other branches of medicine working together in a general hospital, especially when this association brings them into contact with a teaching centre, must greatly increase the scope of treatment of those physical disorders so abundantly found in mental cases, and stimulate interest in psychological medicine.

The establishment of psychiatric and neurological clinics at general hospitals, with provision of beds, as well as out-patient treatment, would form valuable centres for receiving and treating certain early cases and other cases of interest, or for diagnosis, either directly or by transfer from the mental hospital. Patients absent on trial from the mental hospital could, moreover, receive further supervision and treatment if required in the out-patient department of the clinic, a procedure which would be of great assistance in dealing with convalescing cases, especially if medical officers of the mental hospital could hold assistant posts in this department. With amendment of the Lunacy Acts, which there is good reason for anticipating will include a wide adoption of the voluntary system and simplification of the formalities of admission, easy transference between the clinic and mental hospital would be of inestimable benefit to both patients and relatives, and would greatly help in the difficult question of classification in dealing with the varying phases and forms of mental disease.

Students and Nurses.

On the other hand, the valuable material available in mental hospitals would be at the disposal of medical schools, for research work and for teaching students. Clinical assistantships and temporary medical appointments would be available at the affiliated mental hospital, and post-graduate instruction and familiarity with mental disease facilitated. Finally, there is the important question of nursing. As stated above, much attention is now given to training mental nurses, and nurses possessing a general nursing certificate are sought after in mental hospitals. Certificated mental nurses, moreover, are now frequently seconded for the purpose of obtaining a general certificate, and the matrons of most mental hospitals require to possess the double certificate. Few people to-day would criticise adversely the advantage of this double training, or the benefit to any nurse of a knowledge of mental reactions both normal and abnormal, and it is to be hoped that under affiliation reciprocal facilities may be afforded for the higher training of the most efficient nurses.

Psychiatry has often been referred to as the sick sister of medicine. The last report of the Board of Control bears testimony to the strenuous effort that is being made to remove this reproach. Will the general hospitals proffer the assistance that is sought? Psychology—normal and abnormal—is still the weakest spot in the medical curriculum. A combined effort is required to ensure progress and awaken the interest of the whole profession in the mental aspect which is never negligible in all other manifestations of disease.

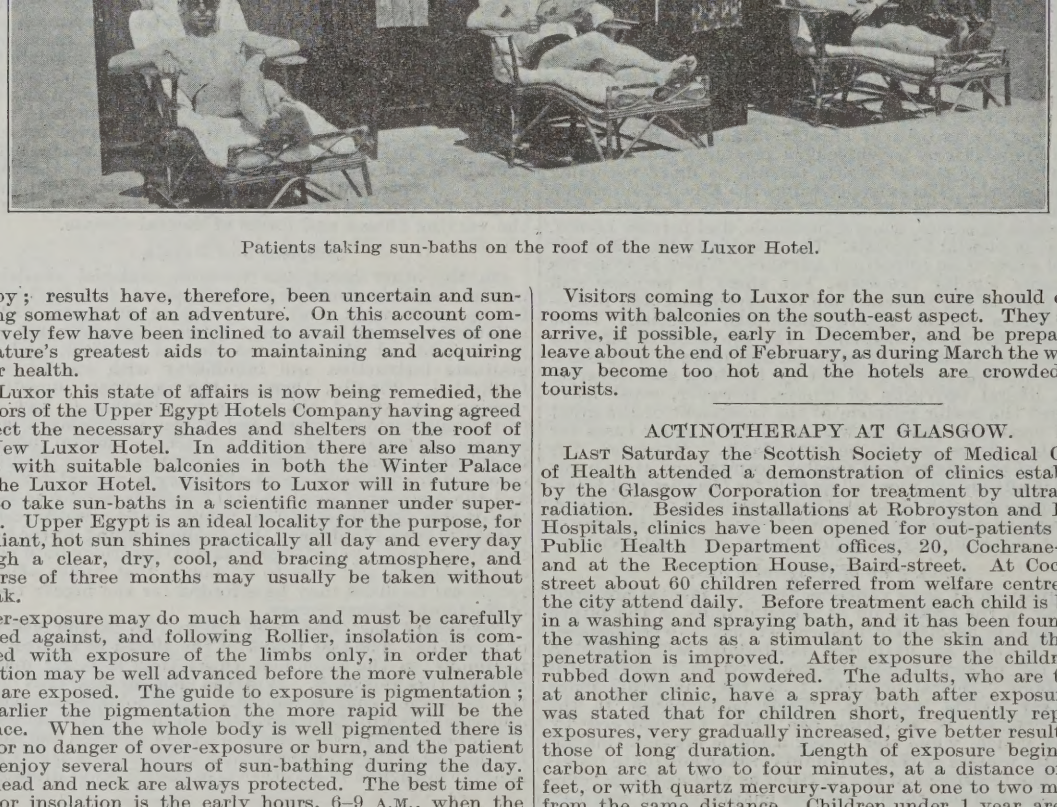
"THE LEECH."

THE most recent addition to medical journals is *The Leech*, of which the first number has just been issued by and for students of the Welsh National Medical School. Its format is pleasing and the subject matter well planned, both serious and frivolous material finding a place. Prof. David Hepburn writes on the Importance of Anatomy, Mr. Lambert Rogers on Thyrotoxicosis, Mr. John Pryde on Biochemistry and Modern Medicine, and Mr. S. S. Budd describes a case of phantom tumour in a girl of 14 years. Miss E. Williams contributes some short notes on the early history of endocrinology and the rest of the issue is filled by reports of students' activities and by articles and anecdotes in lighter vein. Proof reading has, on the whole, been careful ; there is a misprint in the legend to the electrocardiogram on p. 12, where "head" should read "lead" and the name of Dr. Harington, who has recently revised the formula of thyroxine, is mis-spelt. The journal should serve to strengthen the moral of this new school and to promote and maintain contact between its members.

SUN-BATHING IN UPPER EGYPT.

BY GEORGE V. WORTHINGTON, M.B., B.C. CAMB.

FOR years past a certain number of visitors in search of health, and tourists also, have been in the habit of taking sun-baths in a casual way without knowledge and without seeking advice. Each winter season I am called to see a few of them suffering more or less severely from over-exposure, the result of this want of knowledge. In no resort in Egypt has there been provided, up to the present, any proper accommodation or efficient facilities for sun-therapy; results have, therefore, been uncertain and sun-bathing somewhat of an adventure. On this account comparatively few have been inclined to avail themselves of one of Nature's greatest aids to maintaining and acquiring proper health.



Patients taking sun-baths on the roof of the new Luxor Hotel.

In Luxor this state of affairs is now being remedied, the directors of the Upper Egypt Hotels Company having agreed to erect the necessary shades and shelters on the roof of the New Luxor Hotel. In addition there are also many rooms with suitable balconies in both the Winter Palace and the Luxor Hotel. Visitors to Luxor will in future be able to take sun-baths in a scientific manner under supervision. Upper Egypt is an ideal locality for the purpose, for a brilliant, hot sun shines practically all day and every day through a clear, dry, cool, and bracing atmosphere, and a course of three months may usually be taken without a break.

Over-exposure may do much harm and must be carefully guarded against, and following Rollier, insolation is commenced with exposure of the limbs only, in order that toleration may be well advanced before the more vulnerable parts are exposed. The guide to exposure is pigmentation; the earlier the pigmentation the more rapid will be the advance. When the whole body is well pigmented there is little or no danger of over-exposure or burn, and the patient may enjoy several hours of sun-bathing during the day. The head and neck are always protected. The best time of day for insolation is the early hours, 6–9 A.M., when the air is coolest. Later in the day the periods must be shorter and the intervals more frequent.

The subjective effects of sun-bathing include a sense of general well-being and exhilaration if the exposure has been correct; resistance is increased and pain is relieved. If the exposure has been too great, lassitude, headache, and perhaps vertigo are complained of. An overdose may produce acute and prolonged headache, nervous irritability, and insomnia. The objective effects include a slight and temporary rise of temperature and increase in rate of pulse and respiration. The muscular system is improved in tone.

Cases in which insolation is beneficial are the following. Fibrositis and the various forms of chronic rheumatism, including sciatica and other forms of neuritis. These can usually take a prolonged course without break, but individuals liable to attacks of acute gout must proceed cautiously. A sojourn in Egypt has been recommended almost as a climatic specific for rheumatoid arthritis, and the majority of cases are greatly benefited, but not all. A certain number do not improve in a warm climate, even if dry, and do better in the Engadine or other Alpine resort. The history may be taken as a sure guide; if the patient dislikes cold and suffers more in the winter, he should choose a warm place to winter in. Chronic bronchitis and emphysema and chronic nasal catarrh of the hypertrophic variety all derive much benefit; cough subsides and excessive secretion dries up. Anæmic girls require a mild but prolonged sun cure, when they become toned up, rested, and bronzed. Early cases of nephritis do well; the freely-acting skin relieves the kidneys. Early high tension cases improve if sufficient time is allowed. Neurasthenics often show rapid improvement under the action of sun, rest, and quiet. Any septic focus in teeth, tonsils, or nasal sinuses should, of course, be dealt with before the journey is taken.

Visitors coming to Luxor for the sun cure should engage rooms with balconies on the south-east aspect. They should arrive, if possible, early in December, and be prepared to leave about the end of February, as during March the weather may become too hot and the hotels are crowded with tourists.

ACTINOTHERAPY AT GLASGOW.

LAST Saturday the Scottish Society of Medical Officers of Health attended a demonstration of clinics established by the Glasgow Corporation for treatment by ultra-violet radiation. Besides installations at Robroyston and Ruchill Hospitals, clinics have been opened for out-patients at the Public Health Department offices, 20, Cochrane-street, and at the Reception House, Baird-street. At Cochrane-street about 60 children referred from welfare centres over the city attend daily. Before treatment each child is bathed in a washing and spraying bath, and it has been found that the washing acts as a stimulant to the skin and that the penetration is improved. After exposure the children are rubbed down and powdered. The adults, who are treated at another clinic, have a spray bath after exposure. It was stated that for children short, frequently repeated, exposures, very gradually increased, give better results than those of long duration. Length of exposure begins with carbon arc at two to four minutes, at a distance of three feet, or with quartz mercury-vapour at one to two minutes, from the same distance. Children under 1 year are given relatively shorter exposures. Cases of idiosyncrasy occur and it is therefore necessary to estimate the response to initial exposures very carefully and to keep the cases under personal observation during the whole period of treatment. The mothers attend the lamps with the children and carry out the superintendent's timed instructions as to parts of body to be exposed. Exact records are kept at every stage.

At the Baird-street Reception House out-door cases of non-pulmonary tuberculosis are treated. The couches are adapted for lying exposure, and the periods of treatment are carefuly adjusted to the types of case. At Robroyston Hospital Dr. Kathleen Smith gave a lantern description of cases, some of which had shown striking improvement. In the treatment of pulmonary cases with rays, she said, the best test was the pulse-rate. If an increase of ten beats per minute under the rays did not subside within an hour after exposure, the dose had been too much. It was observed that the general condition grew better under the rays, but the local lung condition did not perceptibly improve. The treatment was to be regarded as "still a very doubtful business," and fixation methods were used as well as radiation.

THE

Lloyd Roberts Memorial Lecture

[SUMMARY]

ON

THE CANCER PROBLEM.

Delivered at the Manchester Royal Infirmary on Nov. 9th, 1926,

BY W. E. GYE, M.D. EDIN.,

PATHOLOGIST, MEDICAL RESEARCH COUNCIL'S FARM LABORATORIES, MILL HILL.

THE subject which I have chosen for the lecture is not entirely within the special field of medicine in which Lloyd Roberts was an acknowledged master, but my hope is that what I have to say will be of sufficient interest to make the lecture worthy of the occasion.

I shall begin by indicating at once my general viewpoint on the subject of cancer, and I cannot do better than quote a few words from the introductory note of the First Scientific Report of the Imperial Cancer Research Fund (1904):—

"The combined histological and clinical observations of the last 50 years have established the malignant new growths as a natural group related to each other by fundamental common attributes. The explanation of those common fundamental characters is bound up with the mode of origin of malignant new growths, and is the problem awaiting solution, to be followed by the specific explanation of individual variations as its natural corollary."

I do not know how far this would meet with general approval. There are some very distinguished pathologists who take the view that there is no common cause of the fundamental characters of new growths; to such the search for a cause of the disease is an irrational pursuit. This view I regard as simply obscurantist and so, perforce, I leave it to time and the progress of knowledge to decide the issue.

My task is to tell briefly the essential story of the attempts which have been made to solve the problem set out in the quotation above. Naturally I shall advocate my own views of the solution of the problem, but I am more anxious to show—and if I fail, the fault lies with me and not with the facts—that at least the problem has been defined and brought to a practical stage by the immense efforts of experimental pathologists during the last 25 years.

EARLY RECORDS OF EXPERIMENTAL CANCER.

The earliest record of cancer experiments goes back to 1775 when Peyrilhe attempted to transfer a human breast cancer to a dog. The experiment was a failure. It has been repeated, with variations, over and over again by numerous observers—by Dupuytren, by Langenbeck (1840), Lebert and Follin, Duplay and Cazin, &c.—and invariably without success. Roux and Metchnikoff, and also Jobling, have attempted to transfer human tumours to anthropoid apes and failed. All this early work has shown the impossibility of transferring human tumours to the lower animals. In 1889 Hanau described the first successful transplantation of a carcinoma within the same species. The tumour was of a rat and in structure was a squamous cell carcinoma. It was transplanted into two other rats and formed small nodules in both. Pfeiffer (1890) was successful in transferring a melanotic carcinoma of a mouse to other mice. v. Eiselsberg (1890) successfully transplanted a spindle cell sarcoma of a rat to another rat. Morau (1891) was the first, by the method of transplantation, to cultivate a tumour. He was able to maintain a carcinoma of a mouse for 17 generations over a period of three years by the inoculation of fragments of the tumour into other mice. Firket (1882) and Velich (1898) were successful in transplanting a spindle cell sarcoma and a subperiosteal sarcoma of the rat respectively.

These observations attracted but little attention, and it was not until Jensen, Loeb, and Borrel had turned their attention to them that the significance of such work began to be appreciated. The present era of experimental cancer research may be said to date from the publication of Jensen's paper in 1902. His work, which was carried out with a carcinoma of a mouse, confirmed the observations of the previous experimenters already mentioned, in showing that a malignant tumour can be transmitted indefinitely within the species in which the tumour arises. Further, Jensen was unable to find micro-organisms in the transplanted tumours, and described experiments in which was tested the resistance of the cancer cell to different agents. During the same period Loeb studied a cystic sarcoma of the thyroid of the rat and obtained results essentially similar to those obtained by Jensen. Borrel, working with a mouse carcinoma, added further confirmation.

UNIVERSALITY OF CANCER IN MAN AND ANIMALS.

It will have been observed that the animals used by the experimenters mentioned were rats and mice, and the question now arose as to the occurrence of true new growths in other species. In the First Scientific Report of the Imperial Cancer Research Fund a list is given of the animal tumours examined in the laboratories of the Fund during the year 1903. Tumours of the most varied histological kinds, sarcomata and carcinomata, of the following animals are mentioned: cow, dog, horse, sheep, pig, mouse, cat, hen, Indian parakeet, giant salamander, cod, gurnard, and trout. Since that time observations of pathologists throughout the world have established definitely the fact that new growths occur commonly in all the lower animals, both domesticated and wild. Cancer is not therefore a purely human disease and any explanation of cancer in man must also explain the phenomena presented by cancer in the lower animals. These observations are uncontested and are of fundamental importance; they rule out of account the all too frequent pronouncements that cancer is a disease of civilisation and can be abolished by a return to a "natural" mode of living—whatever that may mean.

In the literature of 20 years ago one may find papers in which doubt was thrown on the neoplastic nature of animal tumours, but the question has now been most thoroughly studied, and the opinion among those most competent to judge is that the animal tumours are true new growths. It is therefore no longer necessary to discuss the point at any length. It is sufficient to say that in mode of origin, in age-incidence, in clinical course, in mode of growth and infiltrative spread, and in the formation of metastases there are no differences between tumours of man and of animals. The same range of tumours, benign and malignant, is met with in animals, and it is with this material that the greater part of experimental studies have been carried on.

THE IMPLANTATION OF TUMOURS.

The method by which a tumour is transferred from one animal to another consists in the implantation, usually subcutaneously, of a fragment of the tumour by means of a trocar or a syringe. From the implanted fragment a new tumour arises. Is the new tumour produced by infecting the cells of the host or does it arise by multiplication of the cells implanted? This question was studied by Jensen by the following technique. A series of animals—mice—was inoculated, in the manner indicated, with a mouse carcinoma, and at regular intervals one of the inoculated mice was killed, the whole of the graft and surrounding tissues fixed and cut in serial sections. In this way the fate of the implanted cells could be followed. Jensen showed decisively for a carcinoma—and his results have been confirmed by numerous observers—that the daughter tumour is derived entirely from the cells of the implanted graft. The central portion of the graft dies but the peripheral cells live; the fate of the

implanted stroma of the graft is difficult to follow, but a new stroma is provided by the host and it is this which nourishes the rim of neoplastic cells of the implanted fragment. The process, then, is a true transplantation and not an infection. Loeb who, studied the same problem with a rat sarcoma was unable to come to a decided opinion. He inclined to the belief that the new tumour was derived partly from the malignant cells inoculated and partly by a process of infection, from the connective tissues of the host. This difference in finding, however, may be merely one of technique and depending upon the difficulty of recognising a malignant from a normal connective tissue cell. Wherever the cells of the implanted tumour are easily distinguished from the cells of the area in which the fragment is placed, the question at issue may be determined by early-stage examinations. The general result of an immense amount of investigation of this character has been to show that the inoculations of tumours are true transplantations, that the daughter tumours are derived from the cells of the original new growths, and that the inoculated animals merely act as a medium in which the cells proliferate. By losing sight of these fundamental facts and by regarding transplanted tumours as *new* growths cancer research has often been led into blind alleys.

Specificity of the Cancer Cell.

The failure of the earliest investigators of cancer to transfer the human disease to lower animals has been mentioned already. This failure probably played a large part in forming the opinion that cancer is essentially a human disease. But it was quickly shown by experimental research that the tumours of animals are transplantable only within the species in which they occur. Thus a dog tumour cannot be propagated in a cat or a cat tumour in a dog. In the light of the discoveries of experimental histologists this is easily understood. It has been shown that inoculations of tumours are transplantations and therefore it could not be expected that the cells of a dog, for example, would grow indefinitely in cats or any other species of animal than the dog. The cell of an animal carries the species specificity. There have been certain observations made which would appear to invalidate this conclusion. Murphy discovered that mammalian tumours can be grown in a developing chick embryo. This discovery has been confirmed by many observers, including myself. From a minute fragment of a mouse carcinoma a considerable amount of growth can be obtained, and the astonishing picture is obtained of mouse epithelial tissue growing rapidly around a stroma provided by the chick embryo, new blood-vessels in which course nucleated red cells penetrating the mass of growth.

The same phenomenon of heteroplastic growth can be obtained in mammals by inoculating a mouse sarcoma into new-born rats. The cells proliferate and form a large tumour which can again be transplanted into new-born rats. In this way it is possible to maintain a mouse sarcoma for several generations in rats. But such work has no real bearing on the cancer problem. The implanted cells *remain mouse cells* and the maintenance of the tumour for a few weeks or months in a series of new-born rats is merely a laboratory trick which leaves the main problem unaffected. Since daughter tumours are derived from the implanted tumour cells it follows that living cells must be inoculated in order to obtain a second tumour. With epithelial tissues this is obvious indeed; inoculations are usually made subcutaneously into the connective tissues and the formation of an epithelial daughter tumour could not be expected to occur from infection of connective tissue cells. It is, however, an experimental fact that when the cells of a tumour are killed, whether by heat or by drying, by means of antiseptics or by mechanical disintegration, the mass of dead material no longer possesses the power of giving rise to a tumour when it is inoculated into a suitable animal. Thus, coincident with the death of the tumour cell there disappears the power of inducing a daughter tumour. The fact fits exactly with the logical deductions from the histological analysis of the changes accompanying the processes of transplantation.

The Cancer Cell a Parasite.

Such beautiful interlocking of fact and deduction served to strengthen the already strong conviction that the tumour cell is itself, as it were, the parasite. Nothing, apparently, is separable from the malignant cell which can induce the formation of a new tumour, and the general opinion has been formed, and is now held almost as a dogma, that the malignant cell is one which, under the influence of many possible inciting causes, has assumed a character or quality which enables it to grow and divide steadily and persistently beyond the needs of the rest of the body. According to this view, the cell is a parasite itself. The position is most clearly indicated by the following facts. It is now possible by following the brilliant work of Yamagiwa and Ichikawa to induce tumours in rats and mice by repeated applications of tar to the skin or subcutaneous tissues. The tumours thus produced are typical new growths and behave in every respect like spontaneous tumours which are caused in some way which we do not yet understand. A tar tumour of a mouse—carcinoma or sarcoma—can be transferred by transplantation to other mice, but living cells are necessary for success. It cannot be successfully transplanted to a rat or to any other species of animal. It is as much an individual mouse tissue as a mouse is an individual mouse. In the same way a rat tar tumour can be transplanted successfully only to other rats and only by the inoculation of living cells. We thus arrive at the interesting position that one and the same irritant acting upon two species of animals will induce new growths in each species, but the new growth in each case is individual and particular to its own species. Clearly the extrinsic agent, the tar, has induced an intrinsic change in the cell. It is thus easy to understand why a microbic hypothesis of the origin of tumours is met with scepticism and indeed contempt. It would be strange were it otherwise. Nevertheless, I believe that these apparently conclusive facts merely conceal the truth.

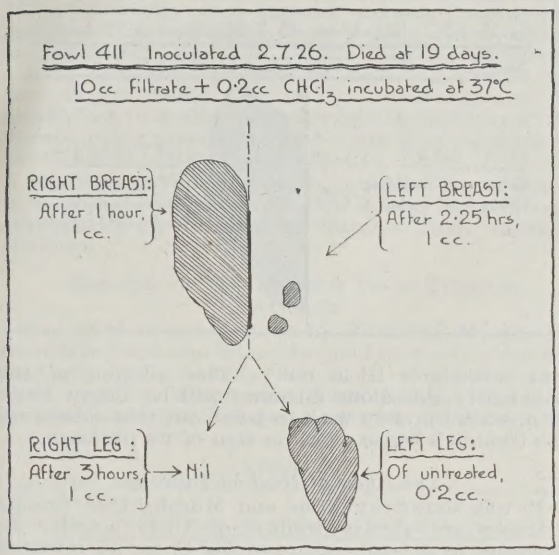
The Rous Fowl Tumour.

And now I come to the exceptions in all this mass of tumours. I refer to the well-known fowl tumours described by Peyton Rous. For the purpose of simplification I shall describe and discuss only one of these tumours, the first to be discovered and the one which is in the hands of pathologists all over the world. It is a spindle cell sarcoma, of primitive type, which occurred spontaneously in a Plymouth rock variety of the domestic fowl. The tumour was first described in 1910 when it was shown to be transplantable in the usual way but exhibiting an unusual degree of specificity for the variety of bird in which it originated. Indeed, the early transplantations were successful only in blood relations of the fowl which bore the spontaneous tumour. Now, after many years of artificial transplantation, the tumour grows in almost any variety of fowl but, like mammalian tumours, it retains its species specificity strictly. That is to say, it will not grow in pigeons, ducks, or any other species of bird, or in any mammal. Now this tumour was found by Peyton Rous to differ from all other tumours examined up to that time in being transferable to fowls not only by means of living cells but also by means of dried tumour tissue or by means of cell-free filtrates. The cell-free filtrates, therefore, contain the tumour's "cause." And, most surprising fact of all, the filtrate is infective only for fowls and causes the reproduction invariably of exactly the same kind of tumour—a spindle cell sarcoma. Thus the agent derived from the tumour cells has the power of exciting the formation again of a new tumour by transforming the normal connective tissue cell of the fowl into malignant cells, and this power is exerted only in one species. It is easy

to believe in the specificity of animal cells, but here apparently the specificity is freed from the cells and is obtained in solution—or at least it passes through a filter.

Of such tumours half a dozen or so have been described; but it does not matter much whether

CHART 1.



the number be half a dozen or half a hundred; the problem to be faced is the same and is challenging to all of us. Before trying to make clear what I conceive to be the problem I will state and discuss briefly the essential facts upon which there is general agreement.

The Rous Tumour a True New Growth.

First, the tumour is a true new growth as judged by the most rigid standards; secondly, filtrates through candles which hold back very small bacteria are able to induce sarcoma formation; and thirdly, some of the properties of the filterable agent are those which we usually associate with living organisms.

The general reaction to the discovery of these tumours was one of surprise that such a tumour should exist, followed by a half-hearted denial of the neoplastic nature of the growth. To-day most pathologists who have studied the tumour agree as to its neoplastic nature. There exists, however, an unwillingness to consider seriously the possibility of the filterable agent being an ultra-microscopic microbe such as we believe exists in certain animal diseases. Some of the more absurd explanations of the peculiarity of this tumour I will simply mention. It has been suggested that the filtrate of the tumour contains an ultramicroscopic cell which, when injected into the muscle of a fowl, enlarges and becomes a normal cell from which the new tumour forms. A modification of this view which has been put forward is that the active filtrate contains a part of the cell from which the normal cell can again regenerate. Such views, I hope, need no reply. They are stated merely to indicate the extremes to which men will go to explain away a fact which runs counter to a strongly held opinion.

Rous and his collaborators in their long researches into the filterable tumours came to the opinion that the balance of evidence was in favour of the agent being a living, filterable micro-organism. Now what is the evidence that such things exist at all? If we take the classical example, and the first discovered, of an animal disease believed to be caused by a filterable virus we shall consider foot-and-mouth disease.

The current belief that foot-and-mouth disease is caused by a filterable virus is founded upon the following evidence. When the vesicular fluid of a lesion in this disease is diluted and filtered through a good candle, and the filtrate injected into a normal animal, this animal acquires the typical signs and symptoms of the disease. The vesicular fluid obtained from the second case may again be diluted and filtered, and once again the filtrate will reproduce foot-and-mouth disease; and so on ad infinitum. The filtrate when examined by ordinary microscopic and cultural methods is sterile, but since the causal agent reproduces itself indefinitely in the bodies of the inoculated animals it must be a living thing and it is, as we have seen, of ultramicroscopic size. Upon this evidence almost all bacteriologists believe that the cause of foot-and-mouth disease is an ultra-microscopic microbe. The evidence produced by Peyton Rous with regard to the filterable tumours was of the same kind and quality and is now more extensive. But opinion against a microbic cause of tumours is strong and few are prepared to accept for tumours conclusions which, on similar evidence, are unquestioned in other fields of medicine.

Let me now state the problem which is before all of us. Thousands of tumours of men and animals have been studied. Large numbers have been cultivated by transplantations. A considerable number of tumours have been induced de novo by means of chemical and other irritants and have been carefully studied. Almost all attempts to find an extrinsic cause—or a cause separable from the cells

CHART 2.

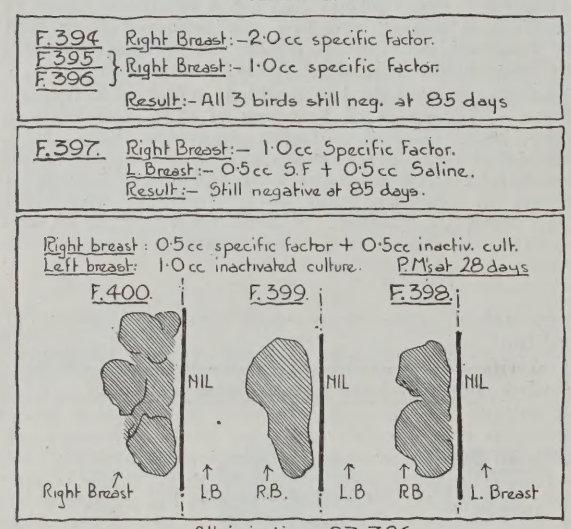
—have failed. But to about half a dozen tumours, of various histological kinds, a cause, a filterable virus, separable from cells has been found. How shall we look upon this astonishing difference? We may regard the filterable tumours as a disease sui generis unrelated to other tumours; in this way we must suppose that a filterable virus plays a part in the causation of certain tumours which is comparable to the part played by tar or soot in others. This attitude to the problem has been general, but I think that it is a mere evasion of a very real difficulty. The problem exposed by the work of

Rous does not consist solely in the isolation and cultivation of a virus. The true explanation of these tumours must in the first place decide whether or not a virus is present; and in the second place, equally important from the point of view of the cancer problem, must give us some understanding of the extraordinary specific character of active filtrates.

For my part I agree most emphatically with Rous, Murphy, and Tytler that "the findings with the chicken tumours largely demolish the theoretical basis on which objections to an extrinsic cause for cancer have been built up." But can these positive findings of Rous be reconciled with the negative results of similar experiments made with the majority of other tumours? I think they can.

CHART 3.



The Filterability of the Rous Tumour.

It has already been pointed out that the exceptional character of the tumour lies in the fact that cell-free extracts are able to cause the formation of a new tumour. This property of the tumour must therefore be carefully studied and we must know how far it is a fixed and constant property. It has generally been looked upon as constant, and the tumour has on this account been set in sharp contrast with mammalian tumours. This is not in accordance with the facts; they are not quite so simple. Peyton Rous remarked in one of his papers dealing with the filterability of his tumour that sometimes, and under the best conditions, cell-free filtrates are unaccountably innocuous. That, I am sure, has been the experience of all investigators who have worked for any length of time with the tumour. In my experience it has been unusual, for example, to obtain a potent filtrate from a tumour which has been induced by the inoculation of dried tumour tissue, or from a tumour which has been caused by the inoculation of filtrates damaged by heat. But when failure to obtain potent filtrates is an irregular thing the most obvious explanation is that the failure is caused by some technical difficulty. Filtration is not a simple, regular process and it is easy to understand irregular qualities of filtrates. But it has now been shown that technical difficulties cannot fully explain such failures. Dr. Andrews and myself have described how a Rous tumour lost its property of filterability and how this property remained absent for more than five months and then suddenly reappeared. During this long period the tumour was transplantable only by means of living cells—that is, it behaved like the recognised tumours of mammals. Clearly, then, this property of filterability is not fixed; all we can say is that generally a filtrate of the tumour is active—sometimes feebly, sometimes intensely; often it is quite inert. And since it has generally been accepted that a potent cell-free filtrate contains the tumour's cause, are we then to say that sometimes the cause is present in the filtrates

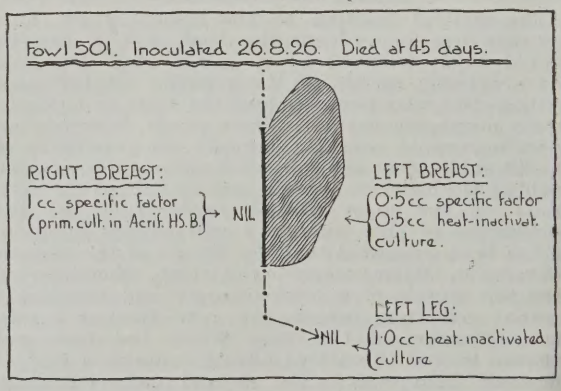
and sometimes it is not? The solution of this apparently ridiculous dilemma will be shown later; at present I merely wish to point out that sometimes the tumour's cause gives no sign of its presence.

The Effect of Heat on Filtrates.

It was shown by Rous and Murphy that tumour extracts are always robbed of their activity by exposure to a temperature of 55° C. for 15 minutes. This statement I can confirm completely. It has been tested very carefully and the method employed is as follows. Not more than 3 c.cm. of the tumour extract is sealed up in a *thin-walled*, hard glass test-tube which is then attached to the bulb of a standard thermometer and completely immersed in a water-bath kept at 55° C. The thermometer and attached tube are shaken gently during the period of heating. Tested in this way, tumour extracts, whatever their initial potency, are invariably inactivated. Rous and Murphy regarded this result

CHART 5.



as evidence that the causative agent of the tumour had been destroyed; and, of course, it looks very like it. Whatever the agent is that is destroyed in such a short time at 55° C. it is evidently very sensitive to heat, and judging by the thermal death points of other viruses, it is not likely to be a virus. This view is supported by a study of the effect of lower temperatures than 55° C. upon a series of filtrates of tumours. A filtrate, usually through a Mandler candle, was made from all the routine tumours obtained during a period of more than six months—in all more than 40 tumours. Each filtrate was tested at temperatures from 45° to 55° C., variations being made from time to time. During the period chosen, the tumour was not very malignant and as

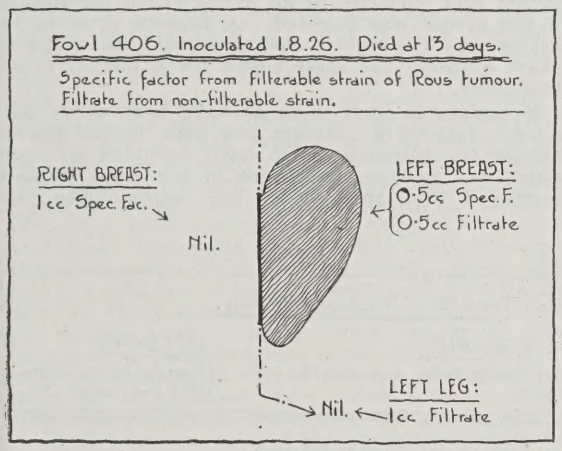
malignancy and activity of filtrates run parallel with one another, the filtrates were not very potent. In a few tests made it was found that 0·5 c.cm. of Mandler filtrate was barely sufficient to induce a new tumour; 2 c.cm. was in each case adequate. All the samples of such filtrates were inactivated by exposure to 55° C. for 15 minutes; often 50° C., and sometimes 45° C. for 15 minutes was sufficient. When suddenly the tumour became exceedingly malignant, metastasising freely in liver, lungs, spleen, and elsewhere, and the filtrate became exceedingly active, inducing tumours in doses of 0·001 c.cm., then it was found that 54° C. for 15 minutes was insufficient to destroy all activity—the activity of the filtrate being merely reduced—but that exposure to 55° C. for 15 minutes was effective.

It is evident from this experience that the substance in the filtrate which is sensitive to heat is variable in amount or in quality in filtrates from different tumours.

Effects of Antiseptics upon Tumour Extracts.

One of the reasons given by Rous and Murphy for their belief that the filterable agent may be a virus was that antiseptics destroy the agent. It is only fair to state that Dr. Murphy has since changed his mind; he now thinks that it is unnecessary to assume a virus.

Chart 6.



His opinion of 1912 seems to me to be sounder than his opinion of 1926. Carbolic acid, corrosive sublimate, toluene, chloroform and ether, hydrogen peroxide, formalin, acriflavine, and hydrocyanic acid are some of the antiseptics which have been tested and they are all effective, each in its own way, in abolishing the activity of tumour extracts. I shall describe briefly the effects of two only of these substances—namely, chloroform and acriflavine.

Chloroform acts very rapidly at incubator temperature. This is shown very clearly in Chart 1. which represents the effect of 0·2 c.cm. chloroform on 10 c.cm. of clear, cell-free, sand filtrate of a very malignant Rous sarcoma. The mixture of filtrate and chloroform was incubated in a large, hard glass tube in a water-bath at 37° C. After incubation for one hour a sample was removed, the chloroform pumped off, and 1 c.cm. then inoculated intramuscularly into the right breast of Bird 411; after two and a quarter hours a second sample was inoculated in a dose of 1 c.cm. into the left breast of the same bird; and after three hours 1 c.cm. was inoculated into the right leg of the bird. The control in this experiment was provided by incubating 10 c.cm. of the filtrate, contained in a hard glass tube, for three hours in the same water-bath; of this incubated extract 0·2 c.cm. was inoculated into the left leg of Bird 411. It is shown by this experiment that in two and a quarter hours the activity of the filtrate has been enormously diminished by the chloroform, in three hours abolished. But since the fowl died in 19 days it might be argued that there was not sufficient time allowed for the dose of filtrate treated with chloroform for the full three hours to manifest its activity. To provide against such a source of error a second fowl was inoculated with 2 c.cm. of such extract; in four months it has not developed a tumour. Thus chloroform acts very rapidly. This, however, applies

only to the ordinary impure chloroform used for common purposes in laboratories. When pure chloroform is used the action is much slower. I am indebted to Dr. Howard Mueller, of Harvard, for the intimation that this might be so.

Acriflavine acts slowly. The experiment represented by Chart 2 illustrates this very well. It will be seen from this that 1 in 5000 acriflavine is unable in three hours to abolish the activity of an extract of a tumour. When such experiments are carried on for longer times—e.g., six hours—it is found that the activity is further diminished but not entirely abolished. In order to inactivate a filtrate it is necessary to incubate the mixture overnight and this often introduces a complication; simple incubation at 37° C. for 18 hours frequently robs a filtrate of its powers to induce tumour formation. In order, therefore, to utilise the action of acriflavine in experiments of an analytical character it is necessary to devise other methods, the details of which are omitted here for the sake of clarity.[1]

Two Factors: both Necessary for Cell Infection.

We know that filtrates of the Rous tumour can be inactivated by heat and by antiseptics. By means of experiments such as the following (Chart 3) it can be shown that the element destroyed by heat is not the same as that destroyed by acriflavine. The experiment illustrated shows that a tumour extract treated with acriflavine was quite inactive; an extract of the same tumour heated to 55°–56° C. for 18 minutes was also inactive. The two inactive fluids when mixed together acquired the power of inducing tumour formation.

The only criticism which can be passed upon experiments of this kind is that the chickens inoculated with acriflavine treated extract happen to be naturally resistant, whereas the others were sensitive. This criticism, however, is not sound. The percentage of resistant birds cannot be determined absolutely, but it is, in any case, very small. Moreover, resistance is a graded quality. When the infective fluid is intensely active it is very rare to find a chicken resistant to its action. Only when the fluids which are inoculated are on the border-line of infectivity does one reveal differences in sensitiveness among any batch of chickens. The criticism, in any case, cannot apply to the next series of experiments. which are illustrated in Charts 4 and 5.

[1] The details and protocols of these researches will appear in a series of papers in the British Journal of Experimental Pathology.

In these experiments the same bird is used as control to the experiment. In the first experiment (Chart 4), the dose of acriflavine treated tumour extract is the same in both breasts; the only difference between the two sides is that in the right breast the diluent is horse serum broth medium, while in the left breast it is heat inactivated extract of tumour. The quantities in such experiments as this are measured with the most scrupulous exactitude. In the experiments represented by Chart 5, the controls, both of heat inactivated and antiseptic inactivated extracts are included on the same bird. Similar experiments, with similar results, have been made with chloroform and with hydrocyanic acid as antiseptics.

From results such as these I am satisfied that the production of a tumour with cell-free filtrates depends

CHART 8.

upon the conjoint action of two elements of the filtrate. One of these is rendered inactive by acriflavine or other antiseptic and is therefore presumably a micro-organism; the other is readily inactivated by heat. As we have seen, it would appear probable that the agent which is destroyed by heat is variable in quantity (or in quality) in filtrates from different tumours. Chart 6, which illustrates eight similar experiments, shows that innocuous filtrates (i.e., filtrates from a "non-filterable" Rous tumour) have the same property of reactivating acriflavine inactivated extracts as have extracts which have been heated to 55° C. for 15 minutes. It follows that inert filtrates are simply filtrates which contain none, or an insufficient amount, of this heat-sensitive but absolutely essential factor. This factor, which I have named the "specific factor," for reasons which will appear later, may be present in variable amount, and it is only because of its activity that the presence of a virus can be shown in the Rous sarcoma. When it is absent the Rous sarcoma, like the average bird and mammalian tumours, cannot reveal its "cause." The peculiarity of the Rous tumour is that it manufactures in varying degree this accessory thermolabile substance.

It is evident from these experiments that the agent which is destroyed by antiseptics (the virus) is unable, acting alone, to induce sarcoma formation. This fact appears to me to be very simple. It has its analogies in general bacteriology where the phenomena are most widely known and appreciated. But the fact, when established in research connected with the subject of cancer, is apparently regarded as a diabolical mystification of a plan and straightforward problem. It is but right to state here that Prof. Borrel, the pioneer of experimental cancer research, has for 20 years held the opinion, on general grounds, that the essential cause of tumours is a virus which requires prolonged preparatory irritation of the tissues before its latent powers can be manifested.

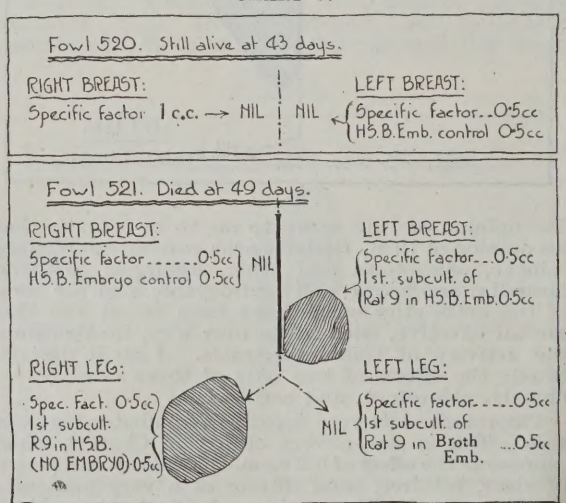
The use of the word "cause" in medicine is unfortunate and is always liable to misapprehension. What is generally understood by the word is, I assume, a factor which must be invariably present in the ætiology of a disease. We cannot, if this be the meaning understood, regard the specific factor as the cause of the Rous sarcoma because it is sometimes absent. The virus—i.e., the element which may be destroyed by an antiseptic—is, so far as my experiments show, always present in the tumour whether the tumour be very malignant or relatively benign. I regard the virus, therefore, as the cause of the sarcoma. Which of these two characters carries the specificity?

SUBSTITUTION EXPERIMENTS.

If an extract of the Rous fowl sarcoma be inactivated by heat and then there be added to it an extract of another tumour, the mixture does not induce sarcoma formation in the fowl or in the animal from which the second tumour was obtained. That is, a heat inactivated extract of the Rous sarcoma cannot be restored to activity by the addition of simple extract of a rat or mouse tumour. But when an extract of a Rous sarcoma is inactivated by means of an antiseptic or by centrifugation, the activity can be restored by the addition of extracts of some other tumours. Chart 7 shows this very clearly. In this experiment the fowl sarcoma filtrate was treated with chloroform, the chloroform removed, and 1 c.cm. of the filtrate was then injected into the right breast of a fowl. Into the left breast of the same animal a mixture of 0·5 c.cm. of this chloroform inactivated filtrate and 0·5 c.cm. of an extract of a tar tumour of the mouse was injected. A tumour grew in the left breast; the right breast remained quite negative. Chart 8 shows the same result for a human breast carcinoma.

Experiments such as these have been made with a large variety of tumours and with normal tissues. Among the tumours which have provided an agent which can replace that agent of the Rous sarcoma destroyed by antiseptics are carcinomata and

CHART 9.



sarcomata, both of man and animals. Normal tissues which have been tested are: embryonic tissues (chick, mouse, rat) more than 150 times; adult tissues of animals, including heart, lungs, muscle, brain, liver, and kidneys—and in one instance, normal human uterus. Not once has it been possible with extracts of such normal tissues to replace the agent destroyed by antiseptic in the fowl sarcoma extract.

My interpretation of such experiments is as follows. In the experiment represented by Chart 8, for example, acriflavine has destroyed in the Rous

tumour extract a micro-organism; this interpretation is in accordance with the well-known antiseptic action of acriflavine. The extract of mammary carcinoma has, as I conceive it, provided a fresh supply of organisms which are able, in virtue of the presence of a sufficient amount of accessory factor of the fowl tumour, to infect the cells of the fowl inoculated.

These experiments show very clearly that the specificity of the Rous tumour extract is carried by the heat-labile agent which has, for this reason, been called the "specific factor." It has already been pointed out that extracts of normal tissues do not provide the agent which reactivates antiseptic treated extracts of the Rous sarcoma. But certain tumours, one of which is a sarcoma of the mouse, have so far invariably failed also. This is one of the most puzzling facts yet met with and I have no explanation which accounts for it satisfactorily. The evidence that the agent which is extractable from many bird and mammalian tumours and which has the power of restoring activity to inactive extracts of the Rous tumour is a micro-organism is as follows: first, the agent is killed by antiseptics, and, secondly, it can be cultivated. The proof of cultivation is obtained by the method described in a recent publication—namely, by using as a medium serum broth to which is added a fragment of embryonic tissue. Chart 9 shows the method of experimentation adopted. Acriflavine treated extract of Rous sarcoma is prepared; to measured portions of this are added in series, (1) a sample of serum broth embryo culture medium, (2) a sample of a subculture in the same medium, and (3) samples of a subculture in different media. Quantities are measured precisely. The result of the experiment represented by Chart 9 shows that the agent from a rat carcinoma survived in horse serum broth embryo and in horse serum broth, but not in broth embryo; it was not present in the horse serum broth control-tube which has been incubated for the same period of time as the cultures. Continuing with subcultures in this way tumours have been obtained with remote—seventh—subcultures in media which contain embryo tissue. But there is a criticism which has been applied, and quite fairly, to these results. It is that possibly we are here dealing with a phenomenon similar to that discovered by Twort and now known as the "bacteriophage phenomenon." It is possible to argue that successive inoculations into tubes which contain living embryo induce repeatedly the production of the agent from the cells of the embryonic fragment. This is not impossible but it is very improbable. It must, of course, be settled before the last element of doubt has been removed.

Conclusions.

Does this new knowledge bring us any nearer to the solution of the problem set forth at the beginning of this lecture? And, further, is the answer compatible with the known facts of cancer structure and behaviour? It seems to me, after considering the problem very thoroughly—and I hope with a sound knowledge of the accepted facts—that in the first place there is no incompatibility between new and old "fact"; and in the second place it shows that there is an agent contained in tumours of diverse origin and of diverse structure which has the supremely important property of reactivating an extract of the Rous sarcoma which has been inactivated by means of an antiseptic. The tumours in this respect are therefore linked together in a way which had never before been suspected; they are indeed a natural group. The agent which is common to these and which links them together in a group, is killed by antiseptics and can be cultivated. Moreover, under special conditions it can be seen and photographed, as has been shown by my friend and colleague, Mr. Barnard. I am satisfied that the simplest explanation of these observations is the correct one—namely, that the agent is a living, filterable microbe and that it is the cause of new growths.

Bradshaw Lecture

ON THE

THEORY OF DIAGNOSIS.

Delivered before the Royal College of Physicians of London on Nov. 4th, 1926,

BY F. G. CROOKSHANK, M.D., F.R.C.P. LOND.,
PHYSICIAN TO THE PRINCE OF WALES'S GENERAL HOSPITAL AND TO THE FRENCH HOSPITAL AND DISPENSARY; CONSULTING PHYSICIAN, NEW END HOSPITAL, LONDON.

PART II.*

THE full importance of the distinction between natural and conventional diagnosticians is only appreciated when medicine is studied in respect of the parallelism that Saucerotte said has ever existed between the history of medicine and that of philosophy—a parallelism that needs no explanation when we realise that, whether in medicine or philosophy, there are two routes by which the human mind has always sought to attain its goal. These routes—those of the sensualist or empirist, and of the Platonist or rationalist—are those followed respectively by the two schools of diagnosis—the natural, or descriptive, and the conventional, or academic—that I have tried to indicate. For the better estimation of our present position, two *points de repère* in the duplex history of medicine and philosophy may be taken: the first, the controversy between Coan and Cnidian in the the fifth century before Christ; the second, the rivalry between Hippocratists and Galenists during the sixteenth century afterwards.

Coans and Cnidians.

It has been said by Boinet that the rival schools of Cos and Cnidus stand for "les deux grandes idées doctrinales qui reviennent sans cesse à travers les siècles après de longs détours et avec des fortunes diverses," and Daremberg, with equal justice, declared that in the Coan writings we find discussion of the organism and of disease; in the Cnidian scriptures that of organs and of diseases. That these differences are essentially *diagnostic* was implied by Littré when he said that the Coans studied the general state that the outcome might be foretold, whereas the Cnidians were more concerned with the diversity of diseases and the distinctions between them.

But it is from the few undisputed writings of Hippocrates the Great that we derive the clearest notion of the Coan diagnosis whereby, after full examination of all relevant detail, related phenomena were simply interpreted in the light of past experience, the resultant judgments being expressed descriptively yet concisely without the confusion arising from the hypostatisation of abstracts and the utraquistic use of names. The classical passage is that in the "First Epidemics," where, speaking of a certain epidemic prevalence, Hippocrates says that he framed his judgments or *diagnosed* by paying attention to what was common to every and particular to each case; to the patient, the prescriber, and the prescription; to the epidemic constitution generally, and in its local mood; to the habits of life and occupation of each patient; to his speech, conduct, silences, thoughts, sleep, wakefulness, and dreams—their content and incidence; to his pickings and scratchings, tears, stools, urine, spit, and vomit; to earlier and later forms of illness during the same prevalence; to critical or fatal determinations; to sweat, chill, rigor, hiccup, sneezing, breathing, belching; to passage of wind, silently or with noise; to bleedings; and to piles.

Here, in a fashion that shows at once the strength and the weakness of *natural* diagnosis, we are given an epitome of what the physician who takes cognisance of the epidemiological as well as the clinical relations

* Part I. appeared in THE LANCET last week.

of a fever must observe. That, to the Coan, judgments were particular for each case, and that general conditions such as fever, and local conditions such as peripneumonia, were mentioned descriptively without linguistic suggestion of attack by any entity or of participation in the "secondary substance" of some scholastic reality—much as when a French physician of to-day says his patient has "a pneumonia" or "a meningitis"—is shown when, in the last sentences of the "Prognostics," Hippocrates begs the reader not to regret the omission of the name of any particular disease, since it is by study of symptoms in each case rather than from accounts of named diseases that the desired knowledge is gotten. A similar diagnostic method is exhibited in the Hippocratic essay on "Wounds of the Head," and is generally employed by surgeons when dealing with injuries.

What we know concerning the Cnidian diagnosis comes in part from the Hippocratic essay upon "Regimen in Acute Diseases," and in part from Galen, in his "Commentary" thereon, and elsewhere. Just as the Coans saw the essential unity of all disease whilst admitting the multitudinous presentations thereof in accordance with personal and environmental singularities, so the Cnidians, in Adams' words, overstrained diagnosis to a system that divided and subdivided diseases into endless varieties or species. For the Cnidians, as for all *conventional* diagnosticians, the aim was not the assay of the patient's state, but the identification of his malady with a standardised ideal.

Since method in therapeusis waits always upon method in diagnosis, Hippocrates differed from the Cnidians, as he said, whenever they interpreted symptoms with a view to determining right treatment: the burden of the "Regimen" is that *he* sought to treat each patient individually and symptomatically; the Cnidians the disease, specifically and rationally. By the Coans every effort was made to "assist nature," to reintegrate the functional unity of the organism that Sigaud finds dissociated in all disease, and to "diagnose"—the translation is literal—

> "to diagnose the asthenias that occur during illness, whether caused by lack of food or other harm, by pain, or the severity of the malady . . . for through knowledge of such things comes safety: through ignorance thereof, death."

But the Cnidians employed those remedies which reason led the physician to deem efficacious in respect of the nominated disease. These differences in practice, however, like those in diagnostic method, flow naturally and consequently from the fundamental psychological differences between two schools, of which one conforms to the natural or direct method of thought and interpretation, and the other to the conventional or indirect and abstract habit. These are rather naïvely indicated by Neuberger when, in sentences that evade the real question, he blames the Cnidians for making "fictitious types of disease founded upon unessential characteristics" and the Coans for their "fusion of clinical entities both pathologically and etiologically distinct."

The cleavage is, indeed, that between those to whom types or universals are of no greater importance than their names, or are at most but shadowy imaginings, and those to whom even the names of such types are something more than mental conveniences, algebraical symbols, or book-keeping fictions, and are representative of *realities*, in a Platonic if not a material sense. Indeed, we are forced to agree with Galen when he said so wisely and so wittily, in his essay "Upon some Tenets of Hippocrates and Plato," that, in the greatest number of cases, cleavage of opinion comes from the failure to distinguish between the particular and the general, "such being the source of disagreement between physicians in respect of the use of barley-water"—a hit at the Coans and Cnidians, this—"and between philosophers concerning the virtues of the soul." Had he lived to-day, he would have said that this failure constitutes also an obstacle to the instruction of the public in matters of personal health, otherwise than in relation to personal diagnosis!

Incidentally, it is of interest that Taylor, who finds the most significant examples of the Platonic usage of the words *idea*, *eidos*, in just those parts of the Hippocratic collection now regarded as Cnidian, should also trace in the Cnidian writings the influence of that Pythagorean school that allied an early form of Platonism to a philosophy of numbers. To-day there are no more stubborn Cnidians than those statisticians who repose their strange belief in numbers upon a realism that allows them to fancy statistical combinations to be something else than patterns of symbols, and statistical results to possess a value that renders inquiry into the original data otiose, if not mischievous.

HIPPOCRATISTS AND GALENISTS.

If the difficulties between Cos and Cnidus, no less than those with which Galen was so greatly concerned between the empirics and the dogmatics, were indeed, as Littré says, a struggle between the fact and the generalisation, or the particular and the general; the essay "Upon some Tenets of Hippocrates and Plato," in which the question of the One and the Many is dealt with in all its obscure profundity, is remarkable as indicating not only Galen's ambition to act as conciliator in respect of the fundamental problem of diagnosis, but his partial breakaway from Coan medicine, and his increasing tendencies to Platonism, as when he declares that Hippocrates wrote confusedly in respect of *genera* and *species*.

His conventionalising tendency is again marked when he approves the saying of Erasistratus that to diagnose is to answer the question: Where and what is the disease? (8–14). So, too, when in the "Commentary" upon the "Regimen" he insists that he alone who knows the constitution of the sick *and* the nature of the disease will be able to devise rationally the remedy. Again, and above all, when, to the four Aristotelian causes—the formal, material, efficient, and final—he adds one more, the typical, or exemplary, by virtue of which the particular, or instance, conforms to the universal, or type. Implicit acceptance of the exemplary cause permeates all modern conventional diagnosis and justifies the notification to public authorities of cases of those diseases which, called into existence by decree from Whitehall, are, in the words of Galen himself, followed by the symptoms as is the substance by the shadow.

It is in virtue of this Platonism that Galen, in spite of his professed devotion to the memory of Hippocrates, became in the sixteenth century century throughout Europe, but notably at Paris, the eponymous head of that party which opposed itself to the less organised body of Hippocratist physicians when was renewed, at the turning point of modern history, the controversy that I have spoken of as that between Cos and Cnidus. If we may consider Guillaume de Baillou (1538–1616), to whom our epidemiologists (and Sydenham not least) owe all, to have been the greatest figure amongst the French Hippocratists, perhaps his master Fernel (1497–1558), who first measured a degree of the meridian, is to be reckoned the greatest of the Galenists. However much Fernel differed from Galen in detail, he, a conventionalist through and through, was never more Galenist than when he tried to shepherd the jarring sects within the fold of his Ramist philosophy and logic. For him a disease was an *affectus*, or *diathesis*, *contra naturam*, and with local or general incidence. Our contemporary systemisers betray his influence in every sentence that they write.

Those who read Baillou and Fernel must agree with Wickersheimer that Le Clerc's epigram, founding the Hippocratic system upon experience and the Galenical upon ratiocination, is absolutely true when applied to the Hippocratists and Galenists of the Renaissance, between whom the difference was less one of doctrine than of method. That is to say, it was one between natural diagnosis in terms of experience, and conventional diagnosis in terms of reasoning. The philosophical difference — fundamentally that which

separated Cos from Cnidus, empiric from dogmatic, and lately occupied some portion of our morning papers in the guise of a discussion at the Oxford meeting of the British Association concerning the nature of species—appears at this time as the aftermath of the mediæval dispute between nominalists and realists which, initiated by the questioned interpretation of a passage in Porphyry's "Isagoge," turned upon the formal query whether or no universals, or *genera* and *species*, have any existence otherwise than in our thoughts.

The scholastic realism that answered this question affirmatively, hypostatising general ideas and holding that in the universals alone is there substantial reality, while standing in line of descent from the early Platonism of Cnidian philosophy and medicine, and the late Platonism of Galen's philosophy and medicine, survives to-day in the obstinate creed of those who profess the belief in clinical entities against which the late Sir Clifford Allbutt fought so long, so ably, and so vigorously.

It carries with it the implication that such *species* as described diseases obey an ascertainable rational necessity and are more than subjective interpretations, being so determined by the nature of things as to be theoretically susceptible of categorical exhaustion by enumeration. Since, even in 1473, until shortly before the birth of Fernel, all professors of the University of Paris had been compelled to take oath to teach only this realism and to abjure all contrary doctrines, it is not difficult to understand the still dominant influence of Galenism in the Faculty of Medicine 50 years later.

The opposed view of the nominalists implied that the name of a universal is but a *flatus vocis*, corresponding to no *ens*, or entity, and that *species* and *genera* are mere names. Since the germs of nominalism are clear in all Coan writings, it is not surprising to find the works of Baillou permeated with the true spirit of the nominalist philosopher and natural diagnostician who seeks eagerly for experience and its synthesis but who distrusts all systemisation and all hypostatisation of abstractions. But, since the philosophical position of those who, at the time of the Renaissance, upheld the doctrines of the Trinity and of the Real Presence, even to extremity, was derived from scholastic realism, whilst nominalism was combated with so much bitterness because of its supposed inconsistency with these dogmas, we may truly say that the diagnostic or methodic issue between the sixteenth century Hippocratists and Galenists relates to the same fundamental ground of difference as that which divided Aristotle from Plato, and, at the time of which I now speak, split the Western Christian church to its foundations.

Clinicians and Systemisers.

With the ultimate discard of Galenism the cleavage between the man who describes a case and him who writes about a disease becomes that, less obvious but still marked, between the clinician and the systemiser: of systemisers, the seventeenth, eighteenth, and nineteenth centuries saw in turn those who made use of chemical, mechanical, botanical, mathematical, organicist, and bacteriological conventions. The schism still persists, though masked by the transference of teaching from the lecture-room and wards to the laboratory, and by the desuetude of reading, whilst at the same time, to-day as ever, every systemiser or conventional diagnostician claims to be a clinician who diagnoses in terms of experience—a compliment not reciprocated, since no true clinician ever claims to be a systemiser. True, system to-day is represented by a jig-saw of systems rather than by any defined pattern, but the existence of the schism is shown by a dissatisfaction which, though perhaps repressed into the collective unconscious of the profession, is yet seeking satisfaction, and is made manifest by a conversion into irresponsibility in thought that is as distressing as the formalism against which it revolts.

There is a feeling that the bald diagnostic convention, of so many definite diseases constituted by so many definite groups of physical signs correlated with so many definite groups of post-mortem appearances, is one that has had its day. So much is shown when doctors declare that there is increasing difficulty in referring cases to a diagnostic *cadre* and that "the type of disease must be changing," though the real ground for complaint should be that the abundance of our experience can no longer be dealt with by methods once adequate. Perhaps, too, we are less confident than formerly of the sufficiency of any affirmations. A few years ago many hoped that bacteriology would render all diagnosis easy, but, as Sir William Job Collins predicted in a brilliant essay, disappointment has come to us. No system of specific pathology has been achieved, and, in spite of great successes, the bacteriological method has cut across many of our most cherished pathological and clinical groupings, as in the matter of the colon bacillus and that of focal infections generally. Under these circumstances some, like Sir James Mackenzie, have reverted to a Hippocratic symptomatology, tempered by neo-methodism, and are undeterred by the wit of those who think it less excellent—almost less moral—to pay greater attention to symptoms than to signs and to diagnose in syndromes instead of in diseases.

Yet those who abash a student by asking him to show a syndrome or diathesis on a plate forget that a *disease* cannot be so shown and that even the Galenists—who did not specifically name throughout their whole range the diseases that were specifically determined for almost every case—recognised that, in order to deal adequately with experience, a whole apparatus of subsidiary devices was needed. So they called into being not only the *morbus*, but the *morbi causa*, the *affectus*, the *effectio*, the *affectio*, the *laesio*, the *symptomata*, and the *signa*. Our present redundance of experience, accumulated as a result of instrumental amplification of our perceptual range and of mechanical facilities for communication and storage, seems to urge us anew towards the devising of fresh conventions.

Already psycho-analysts such as Freud, Jung, and Adler, morphologists such as Arone, Thooris, and MacAuliffe, and characterisers such as Kretschmer and Draper—to say nothing of the endocrinologists—interpret cases, not in terms of diseases, but of personality-types sufficiently indicating the actual or expected reactions of the patient to any given situation. The danger is, however, lest in the absence of a theory of diagnosis new conventions should lead us back into conventionalism, if not realism. To think, as we often do, with concepts that we refuse to define, seems no better than for a carpenter to work with tools whose special uses he will not consider; and it is certainly true that synthetic advance is only made when the integral concepts are first defined, albeit provisionally. To make use of such conventions and concepts as are now being devised, without consideration of the general value of such concepts, is a proceeding that will lead not to fruitful synthesis, but to new and chill academics.

What we must first define, therefore, is the attitude we shall adopt in respect of the two schools of diagnosis: the natural, allied with nominalism; the conventional, allied with realism. We may then well inquire whether, if the philosophic battle be drawn, as perhaps it is, there is anything to be said, pragmatically, in favour of one side or the other! Natural diagnosticians—true clinicians—will, perhaps, always suffer by reason of the lesser fitness of their method for verbal communication. They teach by example rather than by the spoken or written word, and their reluctance to employ verbal symbols as handy labels is ill-comprehended even by those who appreciate results. Always striving towards the simplicity of synthesis, they do not separate disease from the man, or man from his environment. Hence their study of epidemics as illnesses of communities, their therapeutic utilisation of airs, waters, and places, and their insistence upon

personal effort, while causation is to them in each case an infinitely complex relation almost insusceptible of generalisation. *Per contra*, nature, to the natural diagnostician, may become less a subject of observation than an object of superstition, while distrust of classifications may beget mental untidiness; and the study of symptoms, clinical indecision and a neglect of origins, if not an expectancy that slips into fatalism.

But the conventional diagnostician, whatever the convention for which he plumps, if he enjoys all the advantages of the trader who, discarding barter and cash transactions, makes use of financial and currency fictions, runs also the risks of those who, from sheer habit, come to assign real value to their symbols as well as to their concepts. If his faith in specific diseases, with specific etiologies demonstrable by special tests and curable by specific remedies with specific actions, carries him through many a verbal emergency, yet, since this faith has no greater value than the premise upon which it depends—the metaphysical reality of *species* and *genera*—it may betray him at any moment, blinding him to alternative explanations that open up rich fields of experience, and so entangling him in the meshes of his own classifications and dogmas that, finally, in Bacon's words, he worships idols of the theatre. Indeed, just as the naturalist may become a nature worshipper, so may the conventionalist become a gnostic like Galen, or, since most quackery derives logically from realism, a devotee of some magic box.

In these circumstances, what is to be our decision? Shall we elect to remain, like Buridan's ass, halting between two opinions and starved in the literal midst of plenty? If not, must we resign to be, in Sir Clifford Allbutt's words, either treaters of types, fit only to be abstract physicians practising *in vacuo*, or mere empirists who, having but a vague notion of a type, treat the sick man item by item, not appreciating the relative values of the several phenomena of each morbid period? Is there no avenue of compromise or of reconciliation?

COMPROMISE AND RECONCILIATION.

The history of medicine has, perhaps, answered these questions in showing us that security and advance come through ordered balance rather than through unilateral supremacy. But we require some plan or scheme that, in a work-a-day world, will help us to carry on our daily task without losing touch with either side. The difficulty is how may we best relate for practical purposes the thing, the thought, and the name or symbol which, on the other hand, it is equally our duty to distinguish.

One scheme has been set out with great skill by Messrs. Ogden and Richards who, in the "Meaning of Meaning," have given us a theory and canons of symbolisation which it is hoped they will supplement by theories and canons of interpretation and observation.

But historical priority, and for present purposes historical relevancy, pertains to the resemblant scheme of William of Occam, the Invincible Doctor, who died expatriate in, perhaps, 1349, and whose *terminism* or conceptualism—possibly already intended by Aristotle—has so greatly influenced Hobbes, Bentham, Mach, Poincaré, Vaihinger, and Weyl. Occam's life was devoted to the solution of the problem which Galen's epigram lays at the root of all difference of opinion. For him such concepts as those of *genera* and *species* only *suppose* an intention of the mind, and never an existent thing, singly. It has been said recently by Delisle Burns, that Occam, in dethroning the universal and restoring the particular to its proper status, thereby founded science; certainly it was he who, as Vaihinger says, first developed a clear and definite treatment of the *fictional* nature of general ideas or universals and laws in a manner that is still a model for us. He recognised that, although the theoretical non-existence of *ficta*—such as text-book diseases—must be admitted, they are nevertheless to be tolerated as conveniences subject to change in accordance with experience, knowledge, and necessity. He held, too, that nouns, like algebraical symbols, are merely denotative terms whose meaning is conventionally agreed upon; that the universal is not existent otherwise than mentally and as a *terminus*, or predicable, a mental concept signifying univocally several singulars; and that the concept is not so much a thing as an act, having no reality besides the act and the singulars of which it is composed, while the act of abstraction does not presuppose any activity of the understanding or will, but is a spontaneous secondary process by which perceptions are, as it were, stored as soon as several similar representations are present, though in a fading or evanescent state.

This conceptualism, which in its original form stood midway between the nominalism and realism of the scholastic period, has always manifested an impulse towards direct observation, a distrust of abstractions, and an aversion from hypostatisation of abstractions: it greatly paved the way for the work of the Renaissance and, far more than the logic of Bacon, inspired the method of Harvey, as is evident from the introduction to the "De Generatione." It has ever since lain at the foundation of that characteristic English philosophy which, like so much that is English, is none the worse for being better appreciated abroad. In its modern form, as stated by Vaihinger and others, it does seem to reconcile, so far as is humanly possible, the conflicting claims of naturalism and conventionalism in diagnosis.

It is true that whenever stated, in either its original or its modern form, it is at once said to be so commonsensical as to be obvious. But only too many speak as if they believed otherwise, and, in the long run, become the slaves of their verbal symbolisations. Current medical literature is bestrewn with clichés that are meaningless if not connotative of tenth century realism or Hindu demonology, while the demands made on us by the public and sometimes imposed by the State are, as often as not, unjustifiable save on grounds of some primitive realistic belief.

By the neglect of conceptualism we allow great wealth of experience to lie dormant and unused; by its acceptance we come abreast of eager workers everywhere, and cease to pursue conceptual rainbows in the laboratory while neglecting the perceptual at the bedside or in the field. Conceptualism gives us, in diagnosis, the freest scope for observation, unhampered by the fear of forms; it offers us the widest choice of interpretative conventions, and the amplest range of symbolisation, to the clarification of our cognition and the betterment of our communications. Lastly, it teaches that, in respect of any art or calling, the function of science is to furnish fictive concepts and systems of concepts that will economise thought, fructify effort, and tend to the increase of experience, avoiding at once the limitations of nominalism and the illusions of realism.

It may be asked, however, what, in the light of conceptualism, is a correct diagnosis? The best diagnosis that we can attain is that which, when we have observed accurately, interpreted adequately and symbolised correctly, best satisfies the intellectual and affective tendencies and, in the Hippocratic phrasing, enables the physician to do what is right and to constrain to his will, not only the patient, but the attendants and the circumstances.

Absolute diagnosis is a function of Omniscience alone and is exemplified only in the perfect restoration that it is the prerogative solely of Omnipotence to ordain. Absolute diagnosis is not within our physical apprehension; it eludes us, as does the absolute elude the astronomer, the physicist, the chemist, and the mathematician.

But the *idea* of the absolute is present and necessary to all science and every science and, for the science of medicine, is represented by the conceptual miracle of healing in which all diagnostic antinomies are

resolved—the act of creative restoration which, without verbalisation, expresses at once the lesion of function and structure and its effacement.

It is, perhaps, worth reflection that Hippocrates, who said that the physician is most godlike when philosopher, has himself more than any other been spoken of by men as divine. As much was never said of the infinitely more successful Galen, whose system, unshaken during a thousand years, still influences the teaching in every class-room and in every laboratory and still dictates, for the most part, the modality of our formal diagnoses. His system, his rationalisations, and his philosophisings are never credited with the elemental intuition and simple rightness that seem to us inseparable from the clear mind and natural method of Hippocrates of Cos.

THE SURGICAL DIAGNOSIS OF STERNAL PAIN.*

BY A. J. WALTON, M.S. LOND., F.R.C.S. ENG.,
SURGEON TO THE LONDON HOSPITAL.

THE aim of this discussion is to throw light upon the conditions which most closely resemble cardiac and aortic pain. Dr. Parkinson has just ably described the characters of this pain and the methods of diagnosing it from the pain of other medical lesions, and it remains for me to consider those surgical changes which may be mistaken by the practitioner or patient for cardiac disease.

For convenience these conditions can be best grouped as follows: (1) lesions of the thoracic viscera; (2) lesions of the abdominal viscera; (3) local lesions; and (4) spinal lesions.

Lesions of the Thoracic Viscera.

Many changes within the thorax may give rise to sternal or retrosternal pain, but neoplasms of the lung and mediastinum more rightly belong to the province of the physician than of the surgeon, and I shall, therefore, only consider that type of pain which occurs with diseases of the œsophagus.

Carcinoma of the Œsophagus.—With the exception of the rarer varieties situated in the neck, nearly all cases of carcinoma of the œsophagus give rise to a pain which is situated in the midsternal region, and too much stress cannot be laid upon the fact that the site of the pain is no indication whatever as to the site of the obstructive neoplasm. At first the pain is sharp and is only present during the act of swallowing, and it is rather from the nature of its radiation than from its position that a diagnosis can be made. The patient will often state that during the act of swallowing there is a very sudden and sharp pain which, starting in the sternum in front, passes directly through to the back so that he may feel as though he is gripped by some sharp-pointed instrument. Practically never does the pain radiate upwards towards the upper part of the shoulder nor down the left arm; moreover, at this stage it is never increased by exercise. Later, when the growth has eroded beyond the walls of the œsophagus, the pain may be much more constant and may be only slightly increased by swallowing. Under such conditions it is dull, aching, or boring, and may then be more definitely situated at the site of the lesion. As a general rule the diagnosis is made evident by the presence of difficulty in swallowing, but this symptom is by no means always present, and I have seen a case where a carcinoma of the upper end of the œsophagus had widely spread into the apex of one lung and had led to the belief that extensive tuberculosis of the lung was present without ever giving rise to difficulty in swallowing. Generally, however, the increase of the pain during swallowing and the regurgitation of the swallowed saliva, or even of blood-stained fluid, will suggest the nature of the lesion, the presence of which can be easily confirmed either by an X ray examination after a barium meal or by the use of the œsophagoscope.

Cardiospasm.—There is, perhaps, no lesion of the œsophagus which is so frequently overlooked or so often incorrectly diagnosed as this rare and interesting condition. The spasmodic obstruction which has an acute onset and lasts only for a few hours or at most a few days, does not as a rule give rise to any difficulty in diagnosis, since it is associated with a complete inability to swallow. Cases of true cardiospasm are, however, much more insidious in their onset and usually present a long history. I have noticed in some of the cases in my own series that, although the patient sought treatment as an adult, the symptoms dated back to childhood, and cases have been described by Weber, Still, Poynton, and others where treatment was required in early childhood. In the common

* Being one of the opening addresses in a discussion held on Nov. 8th by the Medical Society of London (see p. 1010).

variety patients seek treatment only at about the age of 50 and two distinct groups may be recognised. In the first the chief symptom is pain, which has a more indefinite distribution than that of carcinoma of the œsophagus, being more commonly situated in the epigastrium and passing through to the back; this condition is commonly mistaken for gastric disease. It is at first intermittent, although the attacks may last for a day or two and is increased by the taking of food. Only in the earlier stages before dilatation has become definite will the pain follow the actual ingestion of each mouthful. As dilatation becomes more marked the pain tends to be more in evidence at the end of the meal and thus resembles gastric disease. The second variety, in which the chief symptoms are vomiting or the regurgitation of food, will give less difficulty in diagnosis. When the condition is well established there is a constant feeling of discomfort and fullness, although as the œsophagus dilates there may be spasms of severe pain which then become sternal or retrosternal. The discomfort itself appears also to be thoracic in situation and loses its close relationship to the taking of food. Frequently it becomes more marked as the day progresses, and owing to the distension of the œsophagus may often be associated with dyspnœa and a feeling of stifling. It is in this stage that the patient, and even the medical attendant, may be led to infer that the pain and dyspnœa are cardiac in origin. Vomiting, however, is generally present. It may occur spontaneously or be brought about by taking a deep breath; in other cases it is more evident when the patient lies down, so that he may actually be awakened at night by the regurgitation of the œsophageal contents. A large quantity is brought up and may give considerable relief to the discomfort and dyspnœa. Although the characters of the pain may in this stage somewhat closely resemble cardiac disease, there should not really be any difficulty in making a diagnosis. Careful attention to the past history will usually indicate that the œsophagus is at fault, and an indication of the nature of the change may be given owing to the fact that on attemptimg to withdraw a test-meal the fluid commences to be returned before the tube has reached the stomach. X ray investigation and œsophagoscopy should make the diagnosis clear. Confusion lies rather because an adequate case-history has not been taken than because the individual symptoms are not easy to identify. One would imagine that with the dilatation of the viscus without destruction of its coat there should be a definite area of hyperæsthesia and referred pain. So far, however, I have been unable to elicit the presence of such a symptom in my own series of cases. Possibly this may be due to the fact that the œsophagus lacks a closely connected serous coat, for we are led to believe that referred pain is due to distension of pericardium, pleura, or peritoneum rather than to actual inflammatory changes in the wall of the viscus.

Lesions of the Abdominal Viscera.

It is well known that patients who are suffering from lesions of the upper abdomen often seek advice in the belief that they are suffering from some cardiac disease. This is largely due to the fact that the majority of the so-called dyspeptic pains are, in the early stages at least, referred to the thorax. The difficulty is also increased by the fact that distension of the stomach is not uncommonly associated with dyspnœa and cardiac pain, and, perhaps, even an irregularity of the pulse, and I have found that in some such cases it has been necessary to ask a physician to eliminate the possibility of the presence of cardiac changes in addition to the upper abdominal lesion.

Gastric Ulceration.—As a general rule the pain of a gastric ulcer has so close a relationship to food that but little difficulty is experienced in determining that the lesion is in the stomach. Certain difficulties may, however, arise. In the earlier stages the pain is nearly always referred to the midsternal region, and before penetration of the muscular coat has occurred the ulcer may be associated with a band of hyperæsthesia which on the left side reaches as high as the nipple. In the later stages the area of hyperæsthesia disappears and the pain tends to become more localised. The real point of distinction lies, however, in the fact that with a chronic ulcer there is a sharply localised area of tenderness in the mid-epigastrium. Late ulcers which have penetrated do not show the close relationship of the pain to the ingestion of food, and, in that peculiar variety of ulcer which has a very short history, resembling carcinoma, the pain is frequently constant from the very onset, although the X ray discloses an ulcer which has penetrated deeply into the substance of the pancreas. In this stage, however, the pain is characterised by the fact that it radiates much more widely, and to an area which is distinct from that of a cardiac or thoracic lesion. It may pass upwards to between the shoulders or more commonly to the mid-spinal region, and in one case of my series the patient had been for some weeks under the treatment of a famous bone-setter who had applied massage and manipulations in order to overcome a supposed displacement of one of the small bones of the back. These more definite cases are nearly always, however, easily recognised owing to the changes in the test-meal and the results of an X ray examination.

Acute Dilatation of the Stomach.—Whether it be brought on by excessive feeding, by paralysis of the gastric wall, or by volvulus of the stomach, is nearly always associated with cardiac distress and with dyspnœa. In some cases, if the onset is sudden, the patient may become profoundly collapsed and the pulse may become small and irregular. The more simple forms of acute dilatation are, however, associated with vomiting, and therefore but little difficulty arises in making a correct diagnosis. With a volvulus of the stomach there is no vomiting, and a careless examination may fail to reveal the fact that there is an enormous distension in the epigastrium due to the dilated viscus.

Visceroptosis.—A case of general visceroptosis in which the symptoms are limited to the stomach may resemble a cardiac lesion in that the pain is always increased by exercise or work and is relieved by lying down. Such a condition is frequently associated with distension of the stomach by gas, which will give rise to a certain amount of cardiac distress and may make the patient believe that her heart is at fault. A careful investigation of the history will reveal the presence of past gastric or intestinal attacks, and an examination will show the presence of ptotic changes in the abdomen and viscera, so that no real difficulties will arise.

Lesions of the Pancreas and Gall-bladder.—Chronic inflammatory lesions of these two viscera may give rise to a constant and relatively severe pain which in part is referred to the midsternum, but is usually to be distinguished from a cardiac pain by the fact that it is more marked after food and is referred to a different area. Characteristic of gall-bladder and liver pain is the presence of referred pain in the right shoulder, whereas pain associated with the pancreas is more common in the back and passes up to the left shoulder. In no case does the pain pass up to the front of the left thorax and down to the left arm. Attacks of severe colic, which are so frequent with gall-stones, and are present in many cases of chronic pancreatitis, should not give rise to any difficulty. The suddenness of onset and the severity of pain, its localisation to the upper abdomen, and its sudden cessation are all characteristic and have to be distinguished from an acute disaster in the upper abdomen, such as a perforation or acute pancreatitis, rather than from any interthoracic lesion. The last-named disasters should never lead to an error of diagnosis, for they are associated with the characteristic rigidity of the abdominal muscles.

Local Lesions.

A tuberculous focus in a rib or cartilage overlying the precordium, or the presence of a bony tumour in the

same situation, will at first give rise to localised pain which may be mistaken for a cardiac lesion, but even in these early stages they will probably be associated with definite tenderness on pressure which should give an indication of their nature. Later a tumour will form which, if solid, will not pulsate, but, if fluid, may have a transmitted pulsation from the underlying cardiac beat, and thus may be mistaken for a penetrating aneurysm. In such cases a diagnosis on purely clinical grounds may be difficult, but a carefully taken X ray will nearly always reveal inflammatory changes in the bone which can be distinguished from the simple pressure erosion such as occurs with an aneurysm. However, it is known to us all that cases have occurred in which a penetrating thoracic aneurysm has been opened in the belief that it is an abscess.

Spinal Lesions.

A lesion of the spinal cord—the meninges or the vertebral column—may, if it involves the nerve-roots, give rise to an area of hyperæsthesia which, overlying the precordial area, may simulate the cardiac lesion. There should, however, be little or no difficulty in that nearly all spinal lesions give rise to bilateral hyperæsthesia, or, if there be a unilateral tumour compressing the roots only on one side, there is almost certain to be some interference with the functions of the cord, leading either to changes in sensation or to a spastic paralysis of the legs. With tuberculous disease there should be but little difficulty, for examination will reveal the presence of a rigidity of the vertebra even if there be no deformity or abscess formation. In any case a lesion of the spinal cord is likely to be rapidly progressive unless adequately treated, the only common exception to this being a case of meningitis circumscripta, where the hyperæsthesia alone may persist for a considerable period. In one case of my own there was a band of such hyperæsthesia passing round the thorax, and no other indication of any spinal cord change for nine months after the onset.

THE TREATMENT OF CONTRACTED PELVIS WHEN FIRST SEEN DURING LABOUR.

An Address delivered before the Harveian Society of London on Nov. 4th

BY ALECK BOURNE, M.B., B.CH. CAMB., F.R.C.S. ENG.,

SENIOR OBSTETRIC SURGEON, QUEEN CHARLOTTE'S HOSPITAL AND OBSTETRIC SURGEON TO OUT-PATIENTS, ST. MARY'S HOSPITAL, LONDON.

THE large number of varieties of contracted pelvis and differences in actual size, together with the variations in the size and position of the child and strength of uterine contractions, call for corresponding elasticity of management and treatment. A general theoretical survey of the whole subject of contracted pelvis would take a long time, and therefore I propose to select one particular aspect of the problem, and to deal with it on strictly clinical lines based upon observations made by actual contact with patients seen in a maternity hospital.

One of the most frequent obstetrical emergencies sent to hospital is the patient who has been long in labour and remains undelivered because of some apparent obstruction caused by pelvic contraction. I say "apparent" because an important preliminary to any treatment is the correct diagnosis that the cause of delay is actually due to pelvic obstruction. Indeed, one of the commonest errors in obstetrical diagnosis is the assumption of contraction as a cause of delay or failure to deliver, but of this important matter I shall have more to say later. A further point to bear in mind is that, while the minor degrees of contraction are quite commonly seen, the more serious degrees which cause a really obstructed labour are rare in this part of the country. In fact, very many of the practitioners who have conducted a thousand or more confinements have never met with a severely contracted pelvis, though they will probably remember many cases where there was a difficult delivery by forceps with much moulding of the head. Therefore in any case of delay due to disproportion between the fœtal head and the pelvis there will be a strong probability, based upon the small case-incidence of severe contraction, that vaginal delivery of a living child can be effected.

The Flat Pelvis.

There are two chief clinical types of delayed labour due to disproportion, based upon the two varieties in shape of the contracted pelvis, and it is important to grasp the differences between these two groups which can be ascertained by clinical examination.

In the first group we have the simple flat pelvis in which the principal factor is the projecting sacral promontory encroaching on the true conjugate. The characteristic clinical features here are as follows. The patient has had a prolonged first stage in which the membranes ruptured at the beginning or during the early hours of labour. The head was floating above the pelvic brim before labour, and is still comparatively high in spite of the long duration of the first stage. The failure of the head to descend through the brim and engage with the undilated os, left by the premature rupture of the membranes, is responsible for its slow dilatation, or even stationary condition. In the severer cases the nipping of the cervix by the head against the symphysis and promontory will produce an increasing œdema of its lips. The mother is probably very tired, but at this stage the fœtal heart will still be normal.

The proper treatment, of course, depends upon the answer to the all-important question, Will the head come through the brim? and before we consider treatment it will be necessary to spend a few moments in attempting the answer of this question. Perhaps in no other condition in midwifery are a sound judgment and ripe experience more valuable. A correct opinion is often very difficult to form, but it will be of vital importance to both mother and child.

The Degree of Obstruction.

Let us try to answer the question. The first considerations, before or early in labour, are the pelvic measurements, the amount of overlapping of the head above the symphysis, and the ease or difficulty with which the head can be pressed down into the brim. Favourable indications are the absence of any marked diminution of the measurements, particularly the external conjugate, and considerable difficulty in feeling the sacral promontory by vaginal examination. If this point can only just be touched it need offer very little, if any, difficulty, but if it is easily reached and gives the impression of over-hanging, the brim will probably cause serious obstruction. It is important also to examine the degree, if any, of overlapping. If the head overlaps only the deep surface of the symphysis, and therefore does not actually overhang the superficial border, it will probably mould sufficiently to pass the brim; but any definite overhang indicates a severe degree of disproportion.

So much for preliminary considerations which, we will assume, discover no evidence of severe obstruction. When the patient is examined during labour no further opinion can be expressed until the membranes have ruptured and until pains are strong. The reason for the second is obvious. The membranes must be ruptured to allow the uterus to act directly on the child, and thus press the head hard into the brim. It is necessary, therefore, to re-examine the patient after two or three hours of good pains have followed rupture of the membranes. The points now to be noted are fixity of the head, increasing flexion—shown by the increasing prominence of the forehead and disappearance of the occiput—and descent. Increasing prominence of the forehead with descent of the occiput

is a very favourable sign, and, with absence of overlapping, usually means that the head will pass the brim, given strong contractions and sufficient time. It will be noted that very much information can be obtained by abdominal examination. By the vagina favourable signs will be engagement of the head with the edge of the os, followed by progressive dilatation, and absence of much œdema of the cervix. Palpation of the sagittal suture may yield useful information of the obliquity of the head, but estimation of this physical sign requires very much practice and experience. Unfavourable vaginal signs are failure to reach the head, with maintenance of it in this position, and non-dilatation of the os, which hangs down as a loose fringe, unoccupied by the obstructed head.

Definite Obstruction at the Brim.

After examination on these lines we are faced with three possibilities: (1) the head will not and cannot pass the brim; (2) the head may or may not come through; (3) the progress of fixity, flexion, disappearance of the occiput and dilatation of the cervix is clearly marked, indicating that natural delivery is only a matter of reasonable time.

In the first case the problem is one of the greatest difficulty if the child is alive. The alternatives are Cæsarean section, version, pubiotomy, and craniotomy. If the child is dead or moribund, perforation is obviously the only thing to be done. Of pubiotomy I cannot speak from any personal experience. It is an alternative to craniotomy rather than Cæsarean section. Version is of surprising value in some cases seen early when the uterus can be rendered sufficiently soft by an anæsthetic to eliminate the danger of rupture of the lower segment. Apart from this the chief practical difficulty is the incomplete dilatation of the os, preventing the entrance of the hand into the uterus without laceration of the cervix. If version is decided upon, every care should be taken to dilate the os slowly in order to avoid laceration, and after the leg has been brought down the child should be left alone and not pulled upon, to allow the uterus to complete the dilatation by driving the child's body through the os. The temptation to pull on the leg should be sternly resisted.

Successful version requires considerable judgment and skill. Its possible time of application is limited, for it can only be done when there is sufficient liquor amnii remaining to allow mobility of the child in utero, and, on the other hand, the os must be sufficiently dilated to admit the hand without laceration. Not the least exercise of judgment is that control of the temptation to extract the child's body quickly by traction on the leg which has just been brought down.

It is in this clinical condition of labour obstructed by a flat pelvis with the child alive and the os only partially dilated, with no possibility of the high vertex passing the brim, that Cæsarean section has been urged and practised by some obstetricians. Whether or not it is a safe method depends entirely upon the possibility of infection having already occurred. In the early stage just described, where aseptic precautions have been observed with minimum vaginal examination, the risk to the mother is very small, in spite of the membranes having ruptured prematurely, and it is probably the best way out of a difficult situation. At a later stage, however, when many hours of fruitless labour have passed, with consequent exhaustion of the mother and distress of the child, especially if forceps have been applied and the cervix and perineum bruised or lacerated, Cæsarean section definitely has no place, and cannot be too strongly condemned. It is a source of great danger to the mother, and frequently cannot save the child. The only treatment in such a case is perforation of the head.

Cases of Uncertainty.

The second clinical group is that in which much careful thought is required. Here, at the beginning of labour, it is uncertain whether the head can pass the brim. This group tends to diminish relatively in numbers with increasing experience, but there will always be some cases on which it is impossible to form an opinion in the early stages of labour.

If there is sufficient obstruction present to prevent the birth of a live baby, Cæsarean section is obviously the best treatment, provided conditions are suitable. During the early stages, therefore, the labour may be regarded as a "trial labour"—that is, the patient may be watched closely, after the membranes have ruptured, for signs of descent and successful vaginal delivery; but if observation finds that no progress is evident, then, at the earliest moment for diagnosis to be made, Cæsarean section should be done. It is necessary again to emphasise that throughout the so-called trial labour every possible care must be taken in vaginal examination to prevent infection.

If, however, it is considered that the head will pass the brim there are certain points to bear in mind. We may expect a long and fatiguing first stage occupied in moulding the head, and there is nothing of greater value to the labouring mother than morphia-scopolamine sleep. As soon as it is decided that labour shall run its course, an injection of morphia $\frac{1}{6}$ to $\frac{1}{4}$ gr. and scopolamine 1/150 gr. should be given at once, the scopolamine being afterwards repeated every one or two hours. It is not possible or desirable here to describe fully the technique of this form of narcosis, but let me emphasise its very great value in conserving the physical and moral strength of the mother. Under its influence much pain and anxiety are saved and dilatation is assisted, while the contractions are scarcely altered. Indeed, I regard morphia and scopolamine as essential adjuncts to the treatment of the first stages of labour with a flat pelvis.

In favourable cases—and in most of them treatment is generally successful—the processes of dilatation, moulding and passage through the brim are remarkably easy and quick, and the patient suffers comparatively little fatigue and pain. Nothing can be more striking than the contrast between the condition of the woman made tired and anxious by long hours of unmitigated labour, with slow dilatation, and that of the same woman relieved by an injection of morphia and 30 gr. of chloral by mouth. Apart from the improvement in the general condition, dilatation is usually much accelerated and descent of the head assisted. But if the head becomes fixed in the brim without further descent, help may be given by forceps, provided that the os is dilated and time has elapsed for moulding to produce the maximum adaptability of the head. When the head has once passed the brim into the cavity, forceps will seldom be necessary, as there is now sufficient room for easy descent.

The Abuse of Forceps.

In the third group there is certainly no insuperable obstruction to the birth of a live baby, and we have sufficient data from clinical examination to make it clear that the head can pass the brim. This is one of the most frequent of all emergencies admitted to a maternity hospital as obstructed labour—because of the failure of too early forceps application—and there is none more easily treated. Forceps have usually been applied for two reasons—first, the knowledge that a contracted pelvis is present gives the doctor a bias in favour of forceps which he is anxious to use as soon as possible, and, secondly, the long painful first stage and slow dilatation, unrelieved by morphia and chloral, stimulate the relatives to urge that something should be done. Forceps are then applied through a partially dilated cervix to a high and incompletely moulded head. While the absence of moulding effectually prevents engagement in the brim, the forcible attempt has torn the cervix, bruised the perineum, and still further exhausted the mother. The baby's head meanwhile has suffered stress which will render it less able than before to stand the ordeal of delivery.

No amount of argument or excuses can justify the application of forceps to a high unmoulded head through a partially dilated cervix. It is an ignorant

and stupid practice, and is the cause of more disaster and disability than any other manipulation in midwifery.

After admission to hospital these patients are treated by morphia and chloral and left alone for moulding and full dilatation to occur. A quick spontaneous delivery usually follows, but, if necessary, forceps are reapplied when the head has passed into the pelvic cavity, delivery being effected without difficulty.

The Generally Contracted Pelvis.

The generally contracted pelvis offers a rather different clinical problem. It differs from the flat pelvis in that, when examination or consultation is made on account of delay and lack of progress, with increasing fatigue of the mother, the head is found to have passed the brim and become impacted in the cavity just below the brim. Dilatation of the cervix is probably complete, the head is extremely flexed, there is a large caput, and some œdema of the os. In the treatment of this form of obstruction it is essential again to remember that no attempt at delivery by forceps should be made until sufficient time—at least three hours—has elapsed after full dilatation of the os for moulding to adapt the shape of the head. But here there is not the same likelihood of the absence of moulding as in the same stage of labour with a flat pelvis, because it is only by moulding that the head will have been able to descend into the small pelvic cavity, where it is generally found when attempts at delivery are made. The treatment here is the application of forceps and steady firm traction, which will have to be maintained until the head is clear of the bony outlet. Indeed, sometimes it is the outlet which offers the greatest difficulty. If the child is alive, forceps traction must be maintained consistent with the mother's condition; but if the child is dead or dying the head should be perforated by passing the perforator along between the shanks of the forceps blades as they lie in situ. It is unnecessary to remove them and reapply them after perforation. Traction, after perforation has allowed the partial collapse of the head, will usually succeed in delivering the head remarkably easily compared with the fruitless efforts made before perforation.

In conclusion, I should like to emphasise again that hospital experience shows that the best treatment for the minor degrees of contraction which hold up the head above or in the brim is *morphia*, *chloral* and *time*. Of far more value than ill-advised early application of forceps is the quiet sedative effect of the morphia-sleep which enables the head to mould and the patient to conserve her strength, while she is saved the laceration and damage which so seriously hinders her recovery.

DERMATITIS FROM HANDLING FLOWER BULBS.

BY SIBYL G. OVERTON, M.B., B.S. LOND., D.P.H. OXF.,
H.M. MEDICAL INSPECTOR OF FACTORIES.

"Lily rash" from cutting the stems of flowers, chiefly narcissi, and from handling the bulbs of hyacinths, daffodils, narcissi and tulips, has been known to occur from time to time, mostly, it is believed, in Jersey and in the Scilly Isles. The rash was thought to be due to the acrid juice of the stalks of the flowers, or to the oxalate of lime in the bulbs.

Recently two large firms with extensive bulb packing and sorting departments have been visited, with a view to amplifying knowledge of the occurrence and character of dermatitis from handling flower bulbs. A small proportion of packers and sorters of bulbs were found to be suffering from a strictly localised dermatitis, which extended under the nail, where splitting of the skin caused considerable pain and disability. The longer the nails were worn, the more pronounced was the condition. The nail substance was in every case unaffected. Dermatitis occurred after a few days' work handling bulbs, and was progressive until the worker sought the protection of gloves or finger-stalls, when the condition improved rapidly.

All the workers affected placed the onus of the complaint on tulip bulbs. Those who handled narcissus bulbs exclusively were affected in quite a different way—the skin of the extensor aspect of the terminal phalanges was worn and flaked away by small abrasions and friction. Those selecting, brushing, and packing only hyacinth bulbs were unaffected.

The cause of the peri- and hyp-onychial dermatitis from handling tulip bulbs might appear at first to be friction, but this as the sole agent may be rejected. The onset of the condition within a short time of starting work on bulbs; the course, increasing in severity day by day until protection to the exposed parts is obtained; the fact that those with long, rather than short, nails—i.e., those with more exposure of the finger-tips, are singled out, and that comparatively few are affected—these are all points against the friction explanation. It has been noted repeatedly that where friction causes soreness of the finger-tips there are few physical signs, and complaint is made after some days' work; the condition, also, tends to improve to a marked degree with time and thickening of the skin.

An examination of the bulbs of various flowers readily discloses that hyacinths, narcissi, and daffodils, rather than tulips, would be the chief offenders if friction were the explanation of the peri- and hyp-onychial dermatitis, whereas workers were unanimous in fixing the blame on tulip bulbs. Now the tulip bulb is peculiar in that it is protected by a single layered and rather rigid testa, which easily splits on handling and reveals the bulb substance. The hyacinth is wrapped around with several layers of testa covering, and so are the bulbs of daffodils and narcissi.

It seems not unreasonable to suppose that trauma first occurs, followed by the introduction under the nails of an irritant derived from the bulb substance. In the bulb substance are stored the plant foods, but which of these constitutes the irritant it is difficult to say, as little is known of the chemistry of the bulb. Whatever may be its chemical composition, it was easy to express from a tulip bulb an acrid juice which experimentally produced a subungual irritation in a short time, without the existence of previous trauma.

There has recently appeared a suggestion by the International Labour Bureau that the *Leptus autumnalis*, or harvest bug, is responsible for erythema and conjunctival irritation in workers among hyacinth bulbs (Zeper). I have been unable to verify this statement. Moreover, the type of inflammation was not in any way suggestive of a parasitic origin.

While examining microscopically the covering testa of various bulbs, I found that the testa of the Roman hyacinth, which is fine and flaky, readily produced a fairly intense irritation of the skin of the neck. This was verified by my colleague, Dr. J. C. Bridge, by experimental production of erythema and irritation. There seems here to be a resemblance to the well-known dermatitis from *Primula obconica*, *Rhus toxicodendron*, and other plants.

In conclusion, chronic peri- and hyp-onychial dermatitis is produced by handling tulip bulbs and constitutes yet another of the trade stigmata, the recognition of which may be of great value to the medical observer. A similar condition has not, to my knowledge, been caused by any other occupation.

References.—MacLeod, J. M. H.: Diseases of the Skin, p. 273. Hygiène du Travail, No. 66 (appearing shortly).

PRESENTATION TO A MEDICAL MAN.—On Oct. 27th, at Littlebourne, near Canterbury, Dr. Edward Griffith Freeman Morris was presented with a cheque for £225, a travelling bag, and an illuminated address on his retirement after 37 years of practice. Thirteen hundred people from 14 different villages subscribed to the gifts.

Clinical and Laboratory Notes.

A PECULIAR CASE OF PNEUMOPYOPERICARDIUM.

BY DUNCAN LEYS, M.B. OXF., M.R.C.P. LOND.,
LATE RESIDENT ASSISTANT PHYSICIAN, ST. THOMAS'S HOSPITAL.

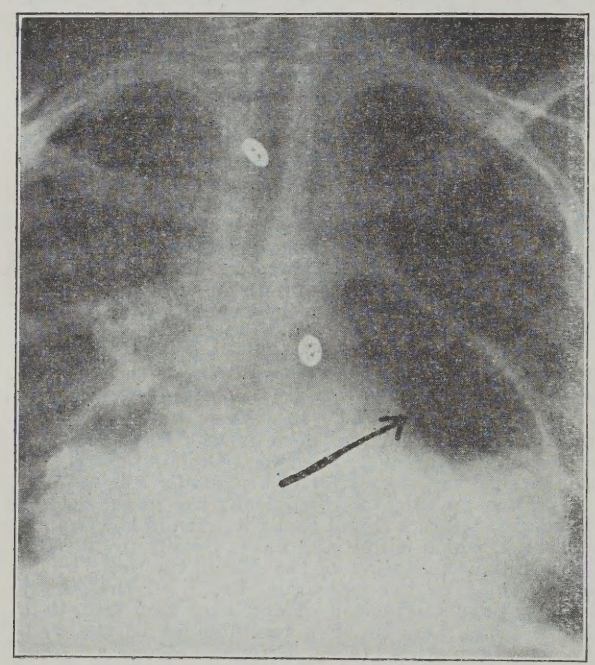
IN view of the rarity and clinical interest of this condition the following case appears worthy of record.

On March 9th, 1925, a boy of 11 was admitted to St. Thomas's Hospital with a week's history of pain in the region of the left shoulder, increased by deep breathing; there had been occasional vomiting throughout the week, and, on the day of admission, a slight epistaxis.

Condition on Admission.—Breathing was at the rate of about 40 to the minute; he was a little cyanosed and somewhat distressed by the pain in his shoulder. Temperature 103° F., pulse regular at 140 to 150, but of poor tension. Physical examination showed some enlargement of the cardiac dullness to the right, and the heart sounds were a little indistinct; there was no murmur or friction. Over a small area at the angle of the left scapula diminished resonance to percussion was found, with tubular breathing and ægophony. The tongue was furred and both tonsils large, but not acutely inflamed; the urine was normal.

Pericardial effusion was suspected, but the physical signs were too anomalous for a definite diagnosis to be made. For the next few days there was no striking alteration in his condition, but on the 15th he complained of abdominal

FIG. 1.



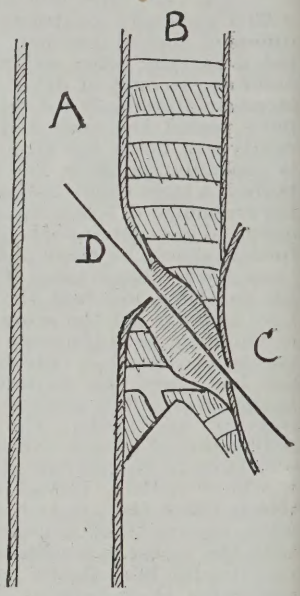
pain, and when examined was found to be rigid and tender in the epigastrium; at the same time the cardiac dullness had almost disappeared, to be replaced by hyper-resonance. The heart sounds were audible, but very faint, the pulse very rapid and feeble, and the general condition much changed for the worse. A blood-count performed this day showed: red cells 4,320,000; leucocytes 20,300; on the following day the leucocyte count had risen to 45,700, and an X ray which, in the prone position, had showed only the appearances of a large effusion, displayed, when taken semi-erect, a large and distinct collection of gas in the pericardial sac, above the fluid level (Fig. 1).

A blood culture taken 48 hours earlier proved sterile. The diagnosis of pneumopyopericardium having been made, operation was decided on, and performed by Sir Cuthbert Wallace.

Operation.—Through a horizontal incision the fourth and fifth ribs in the left nipple line were exposed and resected and the pericardium incised; very foul pus, accompanied by gas, escaped, and the surface of the heart could be seen covered by purulent lymph. *B. welchi* antiserum (40 c.cm.) was given, and the pericardium drained. The boy survived the operation for a full week, his general condition showing remarkable fluctuations; a striking feature of the case after the operation was the abnormally large quantity of purulent fluid discharged from the wound, the dressings being soaked through many times a day. Death took place after a prolonged period of cyanosis and collapse, ending in coma.

Cultures of the pus showed a hæmolytic streptococcus, with *B. mucosis capsulatus* and a gas-forming anaerobe.

FIG. 2.



A = œsophagus; B = trachea; C = pericardium; D = probe passing through sinus from œsophagus into pericardium.

The *post-mortem examination* showed very clearly the peculiar origin of the condition. A caseous and partly calcified tuberculous lymph gland lying behind and to the right of the trachea just above its bifurcation, had, by adherence to and traction upon the œsophagus, created a diverticulum, from which a sinus led, through the remains of the infected gland, directly into the pericardial sac (Fig. 2).

Infection had no doubt taken place from food particles actually entering the pericardial sac, it is probable that after operation a large part of the pus draining from the wound was composed of the milk upon which the boy was being fed. The pericardium was adherent to the lung on either side, and showed an advanced acute suppurative inflammation. The remaining organs showed little pathological change; there was no evidence of consolidation in either lung.

Discussion.

The first account of such a condition appears to have been given by Bricheteau in 1844. Stokes in 1855 had collected three cases. Under the more general heading of pneumopericardium James,[1] in 1904, gives an account of 37 authenticated cases, and emphasises the rarity of the disease by noting that no case of this kind has been observed at the Vienna City Hospital during the 35 years of Schrötter's experience there nor during the whole reign of his predecessor, Skoda. Rigler,[2] reporting a case of tuberculous pericarditis in February, 1925, in which artificial pneumopericardium had been induced under the erroneous impression that the effusion was pleural, refers to Rosler's review in 1918 of 73 cases, all that had been then recorded. His classification of the ætiology is as follows:—

(1) *Infection by Gas-producing Organisms.*—(Five out of James's 37 cases, one of these, apparently secondary to facial erysipelas, recovered.)

(2) *Trauma* (18 of James's cases—i.e., 50 per cent.).—(*a*) By puncture wound of chest wall; (*b*) by penetrating wound of œsophagus (James's own case was caused by the swallowing of a fragment of bone); (*c*) fracture-perforation of ribs or sternum.

(3) *Perforation following disease of* (*a*) pericardium; (*b*) neighbouring organs—e.g., empyema, gastric ulcer.

[1] James: Transactions of American Physicians, 1904.
[2] Rigler: Jour. Amer. Med. Assoc., lxxxiv., 504.

(4) *Artificial:* (*a*) Accidental (as in Rigler's case); (*b*) intentional, in the attempts, attended by very dubious results, to treat pericardial effusion by the introduction of air.[3]

Rigler notes the following characteristics of the condition. The *symptoms* are very variable, depending on the ætiology of special cases; two only are more or less constant—pericardial pain and attacks of dyspnœa, cyanosis, and syncope. On the other hand, the *signs* are constant and unmistakable—a shifting area of tympany over the precordia, accompanied by splashing, gurgling, or tinkling sounds synchronous with the heart-beat, with greatly diminished heart sounds The X rays provide certain confirmation of the diagnosis. The clinical and X ray picture is, according to Rigler, only likely to be confused with one other condition—that of pneumomediastinum, a complication of surgical emphysema following chest-wounds. This, however, can be distinguished by (*a*) the fixed nature of the tympanitic area in varying positions of the body; (*b*) the normal intensity of the heart sounds; (*c*) accompanying emphysema of connective tissue in the neck; (*d*) complete, or almost complete, absence of symptoms, and rapid recovery.

The case here recorded is probably unique in its ætiology. James quotes four cases caused by sinus-formation through tuberculous lymph glands, but the communication was in every case to bronchus or lung; on the other hand, of his œsophageal cases three followed carcinomatous ulceration and three were traumatic.

In conclusion, I acknowledge with gratitude the assistance received from Prof. Hugh MacLean, under whose care the patient was admitted, in preparing this account.

PREGNANCY, HYPERPIESIA, AND MENINGITIS.

BY JOAN L. LUSH, M.R.C.S. ENG.

THE following case is of interest as showing the occurrence of hæmorrhagic meningitis in association with pregnancy and hyperpiesia.

Mrs. C., a married woman of 35, was admitted to University College Hospital complaining of severe headache and pain in the back of the neck with vomiting for three days. Seven years previously she had been in another hospital for six months with Sydenham's chorea, but otherwise had always been healthy.

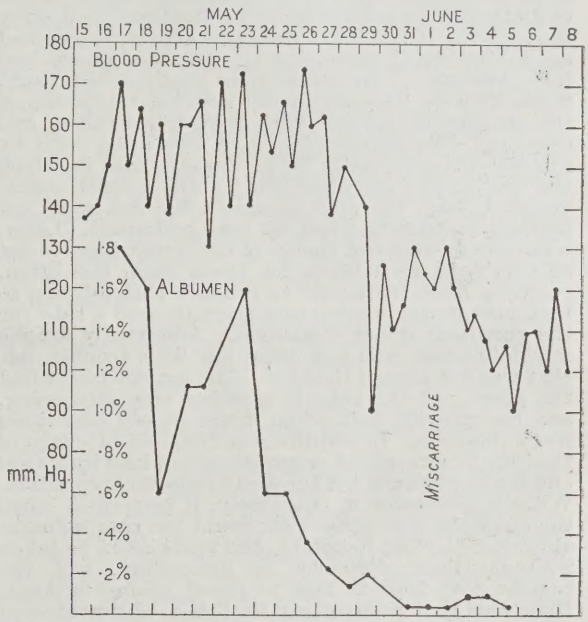
On examination she was found to be pregnant about five months, this being her first pregnancy. Her urine was scanty in quantity and boiled two-thirds solid with albumin, but no acetone was present and no abnormality was found microscopically. The diastatic index was normal. The heart, lungs, abdomen, and nervous system appeared normal; the pulse-rate was 70, the temperature 98° F., and the blood pressure 140 mm. Hg. There was no œdema and the fundus oculi showed no changes. The patient complained of severe pain, chiefly in the back of the head and neck, and the neck muscles were kept in rigid contraction. Drastic purgation was instituted and alkalis and a strong diuretic given by the mouth; aspirin and pyramidon were given in an attempt to relieve the headache. No further vomiting occurred.

Thirty-six hours after admission the blood pressure rose to 170 mm., and the urine was still loaded with albumin. The pain was now greatest in the back of the neck, and Kernig's sign was definitely positive on the left side but doubtful on the right. Both plantar reflexes were flexor, and the knee-jerks were brisk. Lumbar puncture was thought advisable, and about 10 c.cm. of deeply blood-stained turbid fluid were obtained at low pressure. After centrifugalisation the supernatant fluid was deep yellow in colour and gave the Hb bands in the spectrum. There was a definite increase in the lymphocytes, but no organisms were seen, and no growth was obtained on culture. The W.R. was negative. As the headache was slightly relieved by the spinal puncture this was repeated next day, similar fluid being obtained but with some difficulty. The pathological findings had not altered. Stiffness of the neck muscles and a double Kernig were present.

[3] Vide Oppenheimer: Jour. Amer. Med. Assoc., lxxxii., 1685.

The general condition of the patient was good, and pulse and temperature remained normal. The blood pressure varied between 130 and 180 mm., tending for the most part to be higher in the morning. The output of urine continued to be small and the percentage of albumin high. Fœtal movements were felt in the uterus, which contracted under manipulation. In the course of a week the pain in the head and neck had become less severe though the other signs remained as before. Lumbar puncture was done once more, this time yielding clear but bright yellow fluid, which still showed excess of lymphocytes, but no longer gave the Hb. bands.

A fortnight after admission the patient complained of intermittent pain in the lower part of her back and abdomen; about the same time the amount of albumin in the urine decreased markedly, and the blood pressure fell suddenly to 90 mm.; fœtal movements could not be felt, but the pain in the back and pelvis continued. Three days later a slightly macerated fœtus weighing 2-3 lb. was delivered without difficulty. The patient made an uneventful recovery, the blood pressure falling to between 100 and 120,



and the albumin in the urine decreasing to a trace. The headache and stiffness of the neck disappeared entirely, and the patient left the hospital apparently quite well four and a half weeks after admission.

In this case, in the absence of any direct evidence of another cause, it seems reasonable to suppose that the hæmorrhage from the meninges was an unusual manifestation of pregnancy toxæmia but comparable with the hæmorrhages seen post mortem in the liver and kidneys of acute cases. The constant increase in the lymphocytic content of the spinal fluid suggests a possible infective origin, but the absence of fever or increase of pulse-rate is against this view. In spite of the fact that the spinal fluid showed definitely that pathological changes had occurred in the central nervous system and the symptoms were not therefore due merely to meningism of toxic origin, yet the patient never once showed any twitching, fits, or mental change, which are the more usual cerebral manifestations of pregnancy toxæmia. As frequently happens, recovery in this case seems to have been determined by the spontaneous emptying of the uterus. The meningitic symptoms cleared up gradually but the fall in blood pressure and drop in the albumin content of the urine were markedly sudden and probably coincided with the death of the fœtus, though this was not expelled till two days later.

I am indebted to Dr. Batty Shaw for permission to publish this record.

ROYAL SOCIETY OF MEDICINE.

SECTION OF SURGERY.

TREATMENT OF ŒSOPHAGEAL CARCINOMA.

A MEETING of this Section was held on Nov. 3rd, Mr. V. WARREN LOW, the President, being in the chair, when Mr. F. J. STEWARD opened a discussion on the treatment of œsophageal carcinoma, which might, he said, either be frankly palliative or aim at a cure.

Palliative Treatment.—The chief symptom was dysphagia due to the obstruction caused by the growth, and to this palliative treatment was directed. The lumen of the structure could be either enlarged by bougie dilatation, or maintained sufficiently to allow food to pass by inserting tubes of various kinds, or diathermy or radium might be employed to destroy the growth. Or, finally, starvation could be guarded against by doing gastrostomy. All these means had their advocates, but none were really satisfactory. Since 1896 he had seen many cases of carcinoma of the œsophagus treated with Symonds's tubes, and cases not lending themselves to this dealt with by gastrostomy, the latter being usually cases in which the disease was advanced and in which death supervened, though the discomforts in the end were less than if that operation had not been performed. Later, when the speaker had charge of the throat department at Guy's, he used tubes for these cases less often, resorting more frequently to primary gastrostomy, so that now it was many years since he used a tube for the condition under discussion. Admittedly a tube might function well and cause but little trouble, but that was not always the case. The patient might find the placing of the tube in position very distressing, and the gnawing pain when it was in situ sometimes was unbearable. In addition, the frequent blockage of the tube by either food or growth meant its withdrawal and the re-enactment of the dread process of reposition. Witzel's gastrostomy, conversely, if performed when the diagnosis was arrived at, made the case manageable after the first fortnight, and feeds could be taken without either difficulty or discomfort, and the patient soon learned how to guard against leakage. He agreed that gastrostomy for this condition showed a high mortality, but the assurance of freedom from starvation which it gave made it superior to treatment by tube, diathermy, or radium, while the freedom from subsequent irritation seemed to prolong the patient's life. Two of his patients with this condition lived more than five years after their gastrostomy.

Curative Treatment.—The two means so far employed in attempts to cure carcinoma of the œsophagus were radium and surgical removal. The first of these had been widely used for 18 years, but from the standpoint of cure the results attained had been disappointing. It was not denied that radium could destroy carcinoma of the œsophagus, but complete disappearance of the disease under radium was exceptional, a reappearance usually taking place sooner or later. There seemed to be a double explanation for this. Variation in the effect of a given dose of radium might be because of a difference in the resistance of the cells or their surrounding stroma to the rays actually reaching them; it probably was not due to differences of tumour hardness. Possibly the relapses were due to the limited radius of action of the radium, the dose given having been too small to destroy the growth. Guisez, of Paris, of 270 cases so treated, had 30 who survived more than 18 months, two being free after ten years, one five years after, and four three years after. But he used doses of from 100 to 120 mg. of radium bromide divided into three tubes which were placed end to end in a hollow bougie. There were five or six treatments, given every two days, a dosage three times as great as that used by most other people. Guisez made it a point of great importance that the whole vertical extent of the growth should come directly under the emanation. Improved results with radium, Mr. Steward thought, would depend on earlier recognition of the disease and the use of stronger doses.

Dealing next with treatment by excision, he first referred to operation on the mediastinal portion of the œsophagus, remarking that very few patients had survived this procedure more than two or three days. Four chief factors accounted for this gloomy result. The first was a rapid infection of either pleura or mediastinum, or both, and, secondly, the œsophagus was so straight that when it was mobilised there was no slack. Also the absence of a serous coat and the softness of its walls militated against sutures taking a firm hold. Finally, a reconstruction of the œsophagus after resection for carcinoma was a matter of great difficulty. He knew of only three patients having recovered from operation undertaken for removal of carcinoma in the mediastinal part of the œsophagus, and these he described. A study of those cases led Mr. Steward to the conclusion that it would be justifiable to attempt operation in an uncomplicated case in which the growth seemed to be small and localised to the œsophagus if the patient was in good general condition. For a growth in the lower third of the œsophagus he considered that Lilienthal's operation was more suitable, Torek's being the best when the disease was in its middle third. He had explored three cases of limited œsophageal carcinoma, with the object of removal, in people aged 51, 62, and 53. The anæsthetic employed was intratracheal oxygen, and was a very satisfactory one. In two of the cases several intercostal nerves were blocked by using a 1 per cent. solution of novocaine. All three, unfortunately, ended fatally. Yet in some ways the results were encouraging, for the diagnosis of the condition and the selection of the cases erred very slightly.

His deliberate view, Mr. Steward concluded, was that as technique improved better results from operation could be looked for, as the symptoms of the disease were straightforward and distinctive and it was not difficult to decide when a case was suitable for operation. For a long time the disease did not extend beyond the œsophagus. Excision of the carcinoma was a practical proposition, and it was not unreasonable to hope that the history of the surgery of the other organs might be repeated in the case of the œsophagus.

Discussion.

Mr. H. S. SOUTTAR disagreed with Mr. Steward's criterion of operability—namely, that there should be no secondary growths. How often did one find a secondary growth within a year of the origin of carcinoma of the breast? How many cases of carcinoma of the œsophagus survived a year? He went through the records of 18 post-mortem examinations of such cases at London Hospital, and in each it was evident the growth had reached an inoperable stage, for inside the thorax and around the œsophagus the condition was chaos. The patients had died soon after entering the hospital, some of them from gastrostomy. The average duration of their symptoms had been 4·7 months. Mostly, when these cases were first seen by the surgeon, they were already in the penultimate stage. With regard to the statement that better results would ensue if patients were seen earlier, it must be remembered that a man who could not swallow came for advice at once. Some cases had come to him within a few days of the onset of their troubles, and the œsophagoscope revealed a condition which was staggering. Some died before they had any œsophageal symptoms. He contended that in the vast majority of cases by the time the surgeon saw the case operation was out of the question; it was not worth attempting. Most of the cases, in men, were between the ages of 65 and 70, and were bad operation subjects. In the decade 1911–20 16,000 deaths were reported to have occurred from this particular disease in England and Wales; and in the last 30 years three instances of cure had been reported. But were they cured? Was it a cure to have portion of the œsophagus removed and not to be able to swallow?

Mr. Souttar then dealt with the question of relieving these patients and enabling them to eat meals by means of tubes. Hitherto, he said, intubation only aimed at enabling the patient to swallow fluids, and he thought that if larger tubes were used solids such as passed along after proper mastication normally could be negotiated. First, œsophagoscopy must be carried out, and he had had the ordinary œsophagoscope modified so as to carry tubes of varying sizes. Each diameter tube he used was supplied in lengths of 10, 14, and 18 in. In the average male the tubes passed easily. No attempt should ever be made to pass a tube without the aid of the œsophagoscope. He used a modification of Jackson's bougie, as it enabled a view of the tip to be obtained, and it could be passed into the small opening of a stricture. After the stricture was once passed it could easily be opened up, until 11 mm. in diameter was achieved, then a tube of reasonable diameter could be introduced for the purposes of feeding. These tubes were made of German silver wire, in a spiral, which prevented their regurgitation. The tubes seemed to give rise to no trouble, and the immediate result was very satisfactory. Usually the tube was inserted one afternoon, and nothing but water was taken that day; then next morning it was possible to take a breakfast of eggs, fried bread, bread-and-butter, and coffee, while for midday pounded fish and potatoes could be taken. In 26 cases which he had followed up after intubation the average duration of life was 5·3 months. The disease was very relentless, and if a man of 70 years of age could be enabled to swallow a meal in this way it was a very important matter to him. Still, he hoped with others that in a small percentage of the cases it would be possible at a future time to resect the growth with a prospect of cure.

Mr. WALTER G. HOWARTH said he had seen hundreds of cases of cancer of this region, and he had tried all the recognised means of dealing with them, particularly by the radium treatment of the œsophagus, not only with small doses, repeated at intervals of six weeks or so, but by the intensive treatment of Guisez. Looking back, he confessed to a feeling of profound disappointment concerning radium treatment for this disease. He had also, more recently, used diathermy for these cases, but it was difficult to provide a proper electrode; the best he knew was that invented by Mr. A. J. Wright, of Bristol. Diathermy, however, only dealt with the superficial part of the growth, it impinged on the lumen of the œsophagus, whereas many of the growths were intramural and involved the œsophageal wall secondarily. His conclusion was that Mr. Souttar's method was probably the best available at present for dealing with these cases, enabling the patient to live a more comfortable life and take food with some satisfaction. Without such measures many patients could not swallow even liquids, and their saliva was a constant source of intense misery. He had used Mr. Souttar's tubes from the time that gentleman first introduced them, and he gave an account of his experiences with them. With regard to attacking the carcinoma externally, he, the speaker, had removed an œsophageal carcinoma from the upper end of the œsophagus, and brought up the œsophagus to join the cut end of the pharynx to it. That patient was still alive, two years after the operation. There remained a marked cicatricial stricture at the line of suture, but through the minute aperture the patient managed with fair comfort. As to the removal of carcinomata of the middle of the thorax, it was very difficult to say what would be an operable case and what would not, and what was its lower limitation; bismuth meals followed by X ray examination did not help very much. When one of Mr. Souttar's tubes became blocked, small drinks of hydrogen peroxide and water, and abstinence from food for a day, usually resulted in a clearance.

Mr. A. L. APEL attributed great importance to dealing with the teeth of these patients before attempting operation, especially for pharyngeal and upper œsophageal growths. He had seen cases in which at first operation seemed out of the question, but when the patient had been rendered edentulous the growth decreased remarkably. At the Cancer Hospital gastrostomy had been done in a very large number of cases, all under a local anæsthetic. In none was there an immediate mortality, nor the development of broncho-pneumonia. It was simple to measure the extent of the growth in these cases. The patient was placed either on his right side or in the Trendelenburg position, and while so suspended he was given an opaque drink, and the X ray plate was exposed during the act of swallowing, and another when the meal came to a standstill. If the growth was not more than an inch in extent and had not grown into the wall of the œsophagus, probably it was in an operable condition. He had operated upon three cases through the posterior mediastinum, by the method originally suggested by Mr. Wilfred Trotter. One, which he related, lived 11 months, and with no more inconvenience than that caused by continual dilatation. Gas and oxygen, under considerable pressure, was the anæsthetic employed, and the wound in the thorax was closed in an air-tight fashion, so that the lung was never collapsed afterwards. In eight cases he had used the Souttar tubes; three had an œsophageo-tracheal fistula in a fortnight, four swallowed the tubes straight away, and one formed a mediastinal fistula. He made a strong plea for further attempts to really cure this condition. Patients went to their own practitioner, to a physician, or to the nose and ear surgeon, and by the time the surgeon was called it was time to have a gastrostomy. If nothing was done until patients had difficulty with soft solids progress would not be made.

Mr. T. B. LAYTON expressed his agreement with the contentions advanced by Mr. Souttar, except that in the case of a fairly young patient with this disease, otherwise fit, it was worth while to see what operation would do for him. He also agreed that it was always wisest, before doing anything, to render the patient edentulous.

Mr. E. D. DAVIS pointed out that the early diagnosis of carcinoma of the œsophagus was a very difficult matter, especially as dysphagia was often a very late symptom. He had done 70 or 80 œsophagoscopy examinations for carcinoma, and only one of the cases looked like an early one; all the others were advanced, and they died within eight months. He had had a few cases in which Mr. Souttar's tubes proved successful, and in those the growth was in the middle of the œsophagus. If the cancer was at the cardiac end of the œsophagus, it was difficult to place the tube, and one could not be sure whether or not there was coexisting carcinoma of the stomach. The tube was not very successful for them.

The PRESIDENT congratulated the Section on this discussion. His own experience of the disease, from the standpoint of cure, was somewhat gloomy; he would like to share the enthusiasm felt by Mr. Steward and Mr. Abel, and they were probably right, for in regard to the surgery of other organs there was at first a gloomy outlook, until some pioneer came along and, by his keenness, showed what could be done. If improvement was to come in regard to this serious disease there must be earlier diagnosis. He agreed that early in the condition only in a few cases was there any noticeable difficulty in swallowing. On talking to patients after the disease developed it was easy to ascertain that some time before they sought advice they had been conscious of vague pains in the chest, perhaps with a feeling of pressure on the sternum, which were attributed to "indigestion." Who would go to a surgeon, even to a practitioner, for that? He had had no personal experience of Mr. Souttar's tubes, but he had seen many tubes used, and there seemed to him to be something essentially unsound in endeavouring to dilate a carcinomatous stricture. If a foreign body was in close contiguity with a carcinomatous surface, there must be irritation, and from that there would be inevitable reaction. Still, there was undoubtedly

relief of the swallowing difficulties. He was glad of the agreement that the best palliative treatment was provided by gastrostomy, even though the mortality from it was high, which was largely because it was done on every kind of case. Prejudice existed against that operation, not only among the public, but in the profession; doctors said they would rather die than have it done on themselves. In saying that, only the standpoint of the healthy man was being expressed. From the humanitarian point of view, he thought gastrostomy had a great value. He agreed it was the rule for a squamous epithelioma to remain localised for quite a long time; the disease in the œsophagus spread more by contiguity than via lymphatic channels; even in late cases there was not a great deal of glandular enlargement. Patients of his with this condition had never lived beyond two years after the disease was discovered, he could not equal Mr. Steward's five years. He had every admiration for the attempts being made to deal with this disease surgically and with the cure of the condition always in mind.

Reply.

Mr. STEWARD said he had not used Souttar's tubes. Their success in the originator's own hands showed what could be done by intubation in inoperable carcinoma of the œsophagus. He did not himself suggest that every case should be operated upon; but there existed cases in which the growth could be diagnosed while yet it was limited to the œsophagus and in the absence of any signs of secondary deposits. He maintained that if gastrostomy was done early, the patient would lead a comfortable life, more comfortable than if he were wearing a tube. The reason the operation had a bad record was because it was so often used as a last resort for patients in danger of dying of starvation.

SECTION OF OTOLOGY.

THE first meeting of this Section was held on Nov. 6th, when Dr. DAN MCKENZIE, the new President, occupied the chair and opened a discussion on

Diseases of the Outer Ear.

He dealt with certain forms of dermatitis which interested the aurist clinically either because of a difficulty in diagnosis or because of a resistance to treatment. The external auditory meatus was, he said, the only skin-lined cul-de-sac in the body, and it might be the function of the cerumen to ensure the removal from it of the shed epidermal scales, which might otherwise cause symptoms by their accumulation. Furunculosis was a common as well as painful condition, and usually it could readily be diagnosed from mastoid suppuration by the painful swelling of the meatal wall, the tenderness of meatus and auricle, the obliteration of the auriculomastoid sulcus, and the absence of tenderness when compressing the mastoid. Yet cases occurred which presented difficulty in this regard. Sometimes furunculosis, by extending backwards, caused a subcutaneous mastoid abscess closely simulating one due to mastoiditis. The patient might have had previous attacks of middle-ear suppuration, and the membrane might be obscured. Diagnosis must in such cases be postponed until the abscess had been opened. Sometimes, also, simple œdema over the mastoid process might be associated with what seemed like true mastoid tenderness, and it was not clear whether mastoid suppuration was associated with the furunculosis. In such cases the safest course was to open the mastoid process and make an examination. His experience with vaccines for furunculosis had been very variable, and he asked the views of members on the point, and what effect they found from the intramuscular injection of manganese collosol. Sometimes a meatal furunculosis started a spreading dermatitis, and even a cellulitis of the neck and face. Desquamative external otitis was a condition in which the epidermal lining of the canal was in a sodden condition and was shed in continuous sheets, giving the appearance of a cholesteatoma in the antro-tympanic region. It was usually confined to the bony meatus deep to the isthmus. If this condition lasted it caused absorption of bone and dilatation of the deep meatus. The removal of this pultaceous material was, owing to the pain, tedious and difficult, especially when the walls were ulcerated in addition. Syringing was not usually efficacious, and the material must be removed piecemeal by the aid of a spud. Otomycosis was another condition met with not rarely, the aspergillus being the commonest, the mucor mucedo a rarer form. There might be no symptoms until the Malpighian layer of the cutaneous lining was reached. Neglect sometimes led to ulceration. Primary diphtheria of the external meatus had lately occurred in London, and was said to be not uncommon. The chief symptom was severe pain, and a serous discharge was present. In the two cases of it which the President saw the diphtheritic membrane adhered to the deep meatal wall and to the intact tympanic membrane. Diagnosis of the disease was arrived at from culture, and both cases cleared up after one dose of anti-diphtheritic toxin. Constitutional symptoms were absent. An infrequent meatal affection was syphilitic condyloma. In this condition the conchal edge of the canal presented a number of small red papules with linear excoriations, and a painful discharge. Chronic eczema of the meatal lining was often very obstinate, and the help of the dermatologist would be welcome in regard to it, as it was sometimes attended by difficulties of both diagnosis and treatment. It was necessary to exclude suppuration of the middle ear, which might be the cause of the infiltration. When the meatus alone was to blame the discharge was never purulent. Sometimes chronic eczema of the meatus and auricle was of seborrhœic character, and then the scalp would be found to be also involved by it.

Dr. A. M. H. GRAY read a paper entitled Common Affections of the Skin of the Outer Ear. He said inflammations of the skin were reactions to the action of irritants, those reactions only differing in the case of the ear owing to the position and character of the skin. Dermatologists now classified skin affections according to their causative factor, rather than according to their clinical appearances. Many different irritants caused similar reactions, and in some cases the irritant answerable could not be traced. Two kinds of eruptions had to be dealt with, those more or less specific to particular irritants, and, secondly, those due to varying types of irritants, which could, therefore, be spoken of as group reactions. Eczema was a term he applied to a superficial serous inflammation of the skin, which varied according to the irritants applied, or according to the sensitiveness of the particular skin being dealt with, there being present no characteristic by which the causation could be determined. If the kind of irritant was evident, such as solar rays, it was named solar dermatitis, not solar eczema. There could be no doubt as to the great value of X rays in the treatment of chronic inflammatory lesions, whether caused by a septic organism or by causes not yet known, also in conditions due to definite chemical or physical agents. The rays should be given in small doses. The same treatment was of great value, too, in chronic fibrous thickenings about the ear. But when a very acute inflammation was present, or pus formation was in progress, the rays should not be used. X rays should not be applied over long periods for the chronic conditions referred to. In his experience, the best results followed three or four doses of ½ Sabouraud pastille at weekly intervals. If a further treatment at the end of two months did not cure the condition it was probable that the limit of efficacy of the rays for that particular case had been reached. He did not see why an instrument could not be devised which would make possible the safe local application of X rays to the depth of the meatus. Very probably small doses of radium would be also efficacious for the same conditions as X rays benefited, but he did

not know of it having been tried. Furunculosis of the meatus was, he thought, probably due to a lowering of the resistance of the skin to staphylococcus. Sabouraud concluded from investigations he made that it was useless to give vaccines in cases of superficial folliculitis, but that they might be useful in perifollicular abscess cases in which the organisms had passed outside the follicle. The speaker, however, did not quite agree with that authority, because he thought another factor must be considered, and it was questionable whether giving vaccines subcutaneously was a satisfactory treatment of these conditions. Mostly boils were a recurring condition, and the sufferers from them had a staphylococcal hypersensitiveness; desensitisation could not be carried out by giving subcutaneous injections of an antigen, it must be given intradermically in very minute doses. Dr. Gray dealt with a number of other skin conditions.

Dr. F. C. ORMEROD read a short paper on Intractable Dermatitis of the Pinna and External Auditory Meatus which was secondary to chronic suppuration of the middle ear. The paper was based on 33 cases in which inflammatory conditions of the external ear followed suppurative otitis media of from eight to ten years' duration. The treatment followed was the use of various pigments and ointments, such as calamine, mercury, and flavine. In cases of stenosis subitol was used, but this was contra-indicated when eczema or fissures were present. Among the paints used were silver nitrate in water, silver nitrate in spirit, ether nitric, and salicylic acid in liquid paraffin.

A general discussion followed.

Mr. F. J. CLEMINSON read a paper on

Deafness Associated with Fragilitas Ossium

and showed a patient with the condition, a young woman aged 23, who had been deaf since she was 13 years of age, and had recently been getting worse. No specific disease could be held to be the cause, and the onset had been very gradual. She had broken her right arm three times and her leg once. There was a deformity of the face, due to a depression of the left maxilla from before backwards, dating from birth. Her sclerotics were of the greyish-blue colour usual in the condition.

This paper was also fully discussed, as were a number of interesting clinical cases.

SECTION OF LARYNGOLOGY.

A MEETING of this Section took place on Nov. 5th, under the presidency of Dr. ANDREW WYLIE.

Effects of Nerve Anastomosis on Vocal Cord and Diaphragm Movements.

Sir CHARLES BALLANCE gave a cinematograph demonstration of some experimental work which he had been doing, in conjunction with Mr. LIONEL COLLEDGE, showing that paralysis of vocal cords and diaphragm could be cured by anastomosing the recurrent laryngeal nerve with the phrenic nerve. The subjects of the experiment were a dog and a monkey. In the dog, on its right side the phrenic root from the sixth cervical was divided and an end-to-end union of it effected with the recurrent laryngeal. On the left side the trunk of the nerve was completely divided, and then united end-to-end with the recurrent laryngeal. To prevent diaphragmatic palsy, he divided the descendens noni and united its proximal cut end to the distal cut end of the phrenic. The film showed the cords now in full and vigorous movement, and the diaphragm had recovered its contractility. In the case of the monkey, on the right side the cut end of the recurrent laryngeal nerve was united to the side of the phrenic, while on the left side the phrenic nerve was divided and its proximal cut end was united to the distal cut end of the recurrent laryngeal. Every time the operation had been done on animals it was a success, and the research showed that one could cure paralysis of the muscle of the diaphragm by uniting the phrenic to the descendens noni, and cure paralysis, or threatened paralysis, of the depressor muscles of the hyoid and larynx by making an end-to-end union of the cut end of the descendens noni with the lower side of the hypoglossal nerve.

Dr. E. B. BARNES (Northampton) related a case in which Sir Charles Ballance did this operation of union of recurrent laryngeal to phrenic. The patient was a lady aged 52, who sustained an operation on the thyroid in 1925, and following it had aphonia and very severe dyspnœa. Last June Sir Charles Ballance anastomosed the recurrent laryngeal to the phrenic on one side; and about a month later the other side was similarly dealt with. At the present time the patient had well-marked movement of the right cord, and on the left side the arytenoids could be just seen. There had ensued recovery of the diaphragm on both sides.

Sir DAVID FERRIER, who had witnessed the operations and the gradual return to normality, paid a high tribute to the skill of the operations and the significance of the investigation.

HARVEIAN SOCIETY.

THE MANAGEMENT OF CONTRACTED PELVIS: DISCUSSION.

A MEETING of this Society was held on Nov. 4th, Mr. LAMING EVANS, the President, in the chair, when Mr. A. W. BOURNE read a paper on this subject, which is printed in full on another page.

In the discussion that followed, Mr. EARDLEY HOLLAND said that he never did Cæsarean section on the "failed forceps" case; he always perforated. To perform Cæsarean section was gambling on two risks—the chance of infection and the chance that the fœtus had received some injury. Cerebral hæmorrhage in a fœtus in utero produced no visible effect; the heart went on beating, but a possible result of Cæsarean section was a child in white asphyxia which could never be resuscitated. Cerebral hæmorrhage caused respiratory paralysis, and the life of the fœtus in a failed forceps case was not of any value. Of those patients with slight pelvic contraction who were deliberately allowed to go into labour, 80 per cent. delivered themselves or were delivered with a very easy application of forceps. A normal pelvis was constructed to transmit a 7½ lb. baby, but could in most cases allow the passage of an 11 lb. child; it was, therefore, not unreasonable to expect a slightly contracted pelvis to deal with a normal fœtus. Since considering this "reserve capacity" of the pelvis he had largely given up induction of labour. Many obstetricians seemed to be afraid of the "test labour." He had studied the results of induction in his own hospital, judging its necessity by the length of the second stage and the degree of moulding, and concluded that 80 per cent. of the inductions in contracted pelvis were unnecessary. The difficulty of selecting cases for induction was very great; it would be better to set to work and find out how to tell during labour whether a given head would go through or not. To allow moderate cases of contraction to go into labour demanded a much higher standard of midwifery, but was a better course of action. The fœtal and early neonatal mortality of induction cases was 12 per cent., and if the children were followed up to the end of the first year it would probably be higher. He regarded induction for post-maturity as most meddlesome midwifery; it was impossible to tell when labour was really due. Each fœtus should be judged by its size compared with that of the pelvis.

Mr. CLIFFORD WHITE said that he strongly believed in induction. No patient was interested in what happened in 80 per cent. of cases of induction; she wanted to know what was going to happen to herself, and no husband would appreciate a "test labour" on his wife. In these days of late marriages the first labour might well be the last, and, moreover, if the

first were made very difficult the patient might see to it that she never had another. It was the duty of the obstetrician to see that the first delivery was easy and swift. If he found that the head was not well into the brim at the thirty-sixth week it was his custom to see the patient again at the thirty-seventh and, if it would not engage, to prepare for induction, and also to induce labour in any multipara who was ten days over time. The fœtal mortality was not considerable if the baby could be given careful attention. It was a good thing for the doctor not to carry axis-traction forceps with him, as if the head were high he could counter the protests of the relatives by saying that he must fetch or send for special instruments. By the time they came the head would probably have moulded through the brim. "High forceps" were to be avoided if any process of delay would make it possible. If they were used friends should be told that the manœuvre was to enable the patient to deliver herself more easily, then if it appeared that strong traction would be needed to deliver she could be left to deliver herself without causing domestic trouble. An irritated uterus often resulted from repeated intra-uterine manipulations and was apt to be mistaken for tonic contraction, which was, in fact, very rare. The irritation would subside after morphia and an hour's rest. He agreed that self-delivery was the best method after craniotomy and that craniotomy forceps were very dangerous. He would never do a Cæsarean section if forceps had been applied, and did not like it after a "trial labour." Cæsarean hysterectomy was useful for elderly primiparæ when the uterus was probably infected.

Dr. G. DE BEC TURTLE agreed that very few cases of severe contraction were encountered in general practice, the commonest form being the "generally contracted." Walcher's position was of some value in increasing the size of the outlet. The post-mature child was not uncommon and was better induced. The high forceps operation was very difficult; when it succeeded it was best to remove the instruments after bringing down the head and then leave the patient to deliver herself.

Dr. J. THORESBY JONES remarked that out of thousands of cases he had attended he had only had two or three where operative assistance had been necessary.

Dr. W. JAGGER said it was strange that our crass ignorance of midwifery should produce such fortunate results; experts still differed as to the best time and means for interference. The patient herself was generally willing to go on for a time if her pains could be made tolerable, but the anxiety of relatives had to be appeased; cases in practice were not purely scientific. In his opinion early interference was likely to do harm, and it was better to give morphia and wait.

Prof. LOUISE MCILROY agreed that in practice the husband was the chief indication for forceps. She had found morphia most valuable, as in addition to relieving pain it helped to dilate the cervix. She did not agree with Mr. Eardley Holland about induction, and asked what the results were when induction was not performed. In her series of some 6000 hospital cases she had found that Cæsarean sections were gradually disappearing since the use of induction for disproportion. Out of this number only 4·27 per cent. had been forceps cases and there had been no craniotomies. High forceps should never be applied. Imperfect flexion of the head was the cause of most of the maternal damage and fœtal mortality. She induced every post-mature case and the results were good. She regarded the whole discussion as really out of date, since all the cases considered should have been recognised before labour. The vital factor was not a skilful obstetrician at the time of labour but good antenatal care.

Mr. BOURNE, in reply, said that although ideally the treatment of contracted pelvis in labour should be out of date, it was not so found in fact in obstetric hospitals.

MEDICAL SOCIETY OF LONDON.

THE meeting of this Society held on Nov. 8th under the presidency of Sir HUMPHRY ROLLESTON was given up to a discussion on

STERNAL PAIN.

Dr. JOHN PARKINSON said that some might prefer the term substernal, others might choose retrosternal, but the actual words were not of much moment if it were agreed that the patient in complaining pointed to the sternum or passed his hand directly across it. The notion held by the patient as to the depth of his pain seldom gave the physician guidance of any value. He preferred to speak of sternal pain rather than precordial pain, as the latter often merely meant that the pain was felt in the region of the heart, and the apex beat was usually meant. In making a note of symptoms it was better, he thought, to speak of sternal pain, left supramammary pain, and left submammary pain. The thorax, contrary to the abdomen, contained only a limited number of organs. The lungs, being lateral organs, were more likely to give lateral pain, as in pleurisy. Acute tracheitis or bronchitis produced a characteristic soreness behind the sternum. On inspection there might be evident a swelling, a tuberculous abscess, or a pulsating swelling such as a pointing aneurysm. Less frequently this swelling would be found to be a gumma, secondary malignant disease, or a lymph granuloma. Intrathoracic tumours were likely to give other symptoms in addition to sternal pain. In acute pericarditis there might be pain and discomfort, or it might be absent. In early infective endocarditis there might be pain at the lower end of the sternum. In chronic valvular disease, if rheumatic, there was seldom felt more than an aching or a discomfort, and usually the situation of this was below the left breast. Patients with heart failure who persisted in walking about might complain of a feeling of pressure at the lower end of the sternum or in the epigastrium; this pain was worst when they did walk, and this was found to be due to a congestive distension of the liver.

The most important form of sternal pain was that produced as the main or sole symptom in a particular group of cardiovascular diseases. If this pain had a direct relationship to effort, it always meant serious cardiac disease. The degree of the pain varied. It might be discomfort or a definite gripping pressure, though rarely the constriction seemed to encircle the chest; the pain was mostly in front, at the mid-sternum or the junction of middle and upper sternum, its area seldom exceeding the width of the hand. The pain might overflow down the left arm and reach the wrist; there might also be pain in the shoulder, jaw, and neck. Usually this pain ceased when exertion stopped. With advancing disease even slight exertion, such as dressing and undressing, might start the pain. This close relation to exertion almost infallibly pointed to the pain being cardiac. Nervous patients rarely included the sternum in their descriptions of the pain they felt; they spoke of an aching below the left breast. If this was persistent and severe it extended upwards to include the left supramammary region.

Dr. Parkinson said they had been asked to believe that angina pectoris was a disease, yet the greatest authorities had differed in their statements as to its pathology, and even as to the organ involved. The speaker therefore counselled considering it as a symptom. Sternal pain cases would include the vast majority of those of angina, but admittedly angina pectoris might be manifested as a left supramammary pain, extending into the arm and not including the sternum, though this was so in only a minority of instances. Submammary pain alone was practically never indicative of angina. With those exceptions, the speaker thought the earliest and most diagnostic symptom of angina was sternal pain which was felt on exertion. Some thought the term angina should be restricted to cases in which the attacks were strictly paroxysmal.

When the physician had decided that a sternal pain was cardiovascular in origin, he had not reached a proper diagnosis. The disease was cardo-aortic, and what remained to be decided was what particular disease of heart and aorta was operative. It was usually one of four, which could generally be recognised. First, syphilis of the heart and aorta, which was a common cause of sternal pain in men of 35 to 50 years of age, and in them a positive Wassermann, or perhaps a clear history of syphilis, would settle the diagnosis. A blowing aortic systolic murmur, and still more a diastolic, or an accentuated aortic second sound, in the absence of other causes for this, was highly suspicious of syphilis. Sudden death was not unusual in these cases. Still, by treatment, especially early treatment, there was reason to hope for a cure. The second condition was atheroma of the aorta and coronary arteries, and this was a commoner cause of sternal pain than syphilis, partly because sternal pain was more common in elderly people. Though the brachial and radial arteries might be hard and tortuous, the blood pressure might be nearly normal. Diagnosis of this from arterio-sclerosis was largely a process of exclusion. The prognosis was uncertain. In the absence of complications such as cerebral arterial disease, coronary thrombosis, or congestive cardiac failure these patients might live for years, and suffer more from their general disability than from the pain itself. A subdivision of the last-mentioned group was coronary thrombosis, the recognition of which was largely due to American workers. Subjects of this were rarely syphilitic, and nearly always the basis of the condition was a coronary atheroma. The attacks of coronary thrombosis were what were formerly called the status anginosus. So severe and prolonged might this pain be, and so distinct the accompanying shock, that it simulated in many cases acute abdominal conditions, and hence had a surgical interest. This condition had been mistaken for perforation of a gastric or a duodenal ulcer, and for acute pancreatitis. Often apart from any exertion —sometimes in the middle of the night—these patients might have severe angina pectoris, but it did not seem to the practitioner to harmonise with angina pectoris because the pain was too prolonged and had accompaniments which were foreign to true angina, such as a fall in the blood pressure, sweating, and vomiting. Ordinary cardiac failure might supervene, with dyspnœa, and even swelling of the liver and physical signs in the bases of the lungs. In coronary thrombosis the pulse was often notably affected. He thought there had not yet been given due recognition of the importance of coronary thrombosis; it was, indeed, the first step in the logical subdivision of angina pectoris into a number of classes, as the present position and classification of the subject could not be regarded as satisfactory. The fourth category he had to mention was high blood pressure. A small proportion of patients with high blood pressure complained not so much of dyspnœa as of sternal pain. Presumably the coronaries were first affected. In sternal pain from high blood pressure the prognosis, in regard to the danger of sudden death, might be considered to be better, but it must not be assumed that these patients would live longer. No examination could nowadays be held to be complete in chest cases unless the radiographic and cardiographic was included. The inaccessibility of the thoracic aorta to ordinary clinical examination was not yet recognised, but X rays could give valuable information as to heart enlargement, while the electrocardiograph gave increasing information about the state of the myocardium, of which the coronary arteries were the servants.

Summing up his thesis, Dr. Parkinson said that sternal pain coming on with exertion was usually due to cardio-aortic disease, and if severe and prolonged, even apart from exertion, it usually indicated coronary thrombosis. Sternal pain was not synonymous with angina pectoris, but it could be held to include most of the cases so-called. The diagnosis might be completed by deciding what pathological lesion was the cause of the pain. If the use of the term "sternal pain" or "cardiac pain" were more general, even at the expense of dropping the term "angina pectoris," he thought it would result in an earlier, perhaps a more certain, diagnosis of cardio-aortic disease.

Mr. A. J. WALTON then made the communication on the surgical diagnosis of sternal pain which appears on p. 999 of our present issue.

Discussion.

Sir JOHN BROADBENT said that 30 years ago cases of angina pectoris were always attributed to "fatty heart." Now many thought there was no true case of angina which was not associated with coronary sclerosis. Sir James Mackenzie, however, said that it was due to a failure of contractility, and that had been the speaker's own experience. In the cases of very large hearts associated with valvular disease there was seldom cardiac pain, and the anginal pain was invariably associated with exertion. There were two definite classes of cases. The heart issued a signal of distress because it was faced with a call for effort it could not give, and this inability might arise either from coronary sclerosis or from inability to supply the blood needed to deal with the situation. He had seen cases in which, in the absence of syphilis, by giving attention to the mode of life and taking matters easily, there had ensued a good recovery and a further 10 or 15 years of life. But the cases of the kind in which there was a positive Wassermann reaction were, in his experience, almost invariably fatal. He had seen cases in which there was gastric pain definitely related to the taking of food, and the seat of intense pain was the sternum. There was no more difficult class of case to give a prognosis upon than that of sternal pain, because of the variety of more or less obscure conditions which might give rise to it.

Dr. A. BLACKHALL MORISON said the only cases pertinent to the present discussion in which there was danger of unnecessary surgical intervention were those in which there was a sudden attack of coronary thrombosis, for there in addition to its suddenness, the pain was usually central and epigastric. These cases always seemed to be fatal. It was remarkable how few heart cases had been thoroughly examined post mortem; often if one structure was investigated, another was omitted from the survey. He thought it was not so much blood pressure as the blood stroke which induced the attacks of angina, and his habit had been to divide anginal cases into direct and indirect.

Dr. E. P. POULTON referred to cases in which the pain was of a dyspeptic character, and was produced in the œsophagus from mechanical causes. The heart, he thought, had the power to produce similar reflex pain in the œsophagus, and this would, perhaps, explain the belief of one authority that all cases of angina pectoris originated in the œsophagus. The pain of heart-burn could be shown to disappear with peristalsis, and some of the pains described in the present discussion were mitigated by the patient swallowing. Examination of the movements of the viscera under X rays after giving opaque food seemed to confirm the views he was advancing. Experiments were made by placing an inflated bag in the œsophagus, and showed that the pain was a tension pain. Contractions were found to abolish pain.

Dr. J. A. RYLE combated the idea that distension of a viscus caused pain. When a diseased stomach, gall-bladder, or kidney become distended, there was usually a lessening of the pain originally present; it was when a hollow viscus was trying to overcome obstruction that pain, the pain of tension, was felt. There seemed good reason for believing that the pain of angina pectoris was of arterial origin, and for saying that it was produced in the coronary arteries. There existed a perfect analogy in the case of so-called intermittent claudication; in both there was pain of great intensity caused by effort and disappearing when rest was taken, and in the latter there was good reason for believing the pain was produced in the artery. When pyloric stenosis caused pain, somatic signs were absent.

Dr. PARKES WEBER agreed as to the importance of subdividing cases which formerly were grouped under

the one term angina pectoris. He suggested that a good working division was into cases due to obstruction in the coronary arteries and those not so due. In the living patient such a subdivision was admittedly difficult, but it could be attempted. He did not think cases associated with syphilis should be put into a separate group. He proceeded to discuss the analogy of angina pectoris with cardiospasm.

Dr. D. M. BARCROFT spoke of cases in which from some simple cause the patient had a feeling as of a gripping at the heart. Mostly these yielded to trinitrin, but he would like to know how they could be dealt with, as these people suffered badly from lack of confidence through fearing an attack.

Dr. W. W. STOCKER referred to pains originating in the stomach which were felt behind the sternum, and related a personal experience.

Sir CHARLTON BRISCOE discussed the various causes which could give rise to the same kind of pain, and showed, by lantern slides, composite charts of seats of pain in various conditions.

Dr. JOHN FAWCETT said that all recognised the various anatomical conditions associated with angina, and their complete absence in some cases, but until some explanation was forthcoming as to why angina pectoris appeared so frequently in one grade of society and hardly ever in hospital patients, there must remain an important region yet un apped. There must be causes at work in the production of angina pectoris which were not covered by present knowledge.

Dr. H. A. DES VŒUX contended that the person most favourably placed for observing angina was the general practitioner. Yet it was seldom the general practitioner had the opportunity of knowing what was the end result of his cases, even when they terminated in hospital, where there were facilities for post-mortem examination. He gave an account of some cases he had encountered.

Reply.

Dr. JOHN PARKINSON said there was much evidence favouring the idea that the myocardium was a possible source of sternal pain. He agreed that the prognosis in syphilitic cases might be very serious. The explanation as to why hospital patients did not have angina pectoris was beyond him, and he had not seen any solution of that fact.

Mr. WALTON said he had found sympathetic nerve division very unsatisfactory as a measure for mitigating the pain. It was his experience that in the early stages of acute dilatation there was a definite severe epigastric pain, which passed when the tension of the muscle ceased.

NOTTINGHAM MEDICO-CHIRURGICAL SOCIETY.

A MEETING of this Society was held on Oct. 28th, when Dr. C. W. BUCKLEY, the President, occupied the chair, and Dr. H. WARREN CROWE read a paper on the basis and practice of

Vaccine Treatment in Chronic Arthritis and Rheumatism.

He said that the Rheumatism Committee appointed by the Ministry of Health had divided arthritis into :— 1. Rheumatoid arthritis : a general disease occurring in younger people, in which nerve symptoms predominated, and bony changes were inconspicuous. 2. Osteoarthritis : a local disease occurring in more elderly people, general health good, bony changes marked, and usually confined to the larger joints. 3. Arthritis, not classifiable : an artificial group which was put in to help the panel practitioner when confronted with an aberrant case. 4. Gout : from this communication gout wae excluded, since it was not amenable to vaccine treatment.

Medical opinion was steadily veering towards the view that fibrositis and chronic arthritis, excluding gout, were microbic in origin. The question that next arose was, What were the microbes involved ? Evidence had accumulated to show that these were of two main groups, streptococci and staphylococci. The evidence for the former rested on a great many considerations, perhaps the chief of which was the fact that practically all infective foci contained streptococci. These were essentially of the non-hæmolytic type. The evidence for staphylococci was rather more direct, inasmuch as these organisms were found to grow in pure culture from pieces of bone and tissue obtained from open operations on arthritic joints ; whereas, in a large number of control cultures of bone and other tissues, both normal and diseased, no staphylococci had been found. The staphylococci isolated were of the variety, *Staph. epidermidis albus ;* they had been called by the speaker *Micrococcus deformans.* A. E. Wright had shown that streptococci and staphylococci were the only organisms which could live in blood serum ; it was for this reason that he had called them serophy s. Dr. Crowe suggested that whilst streptococci were the chief infecting organisms in fibrositis and osteoarthritis, and *M. deformans* in rheumatoid arthritis, in the great majority of cases both types of microbes were involved. In this way were to be explained the " arthritis, unclassifiable " of the Rheumatism Committee. This group could be more rationally called mixed arthritis. Theoretically, these diseases should form an ideal ground for treatment by vaccines. Yet medical opinion had been definitely adverse to this form of treatment ; this was not pure conservatism, but was due to the number of failures which had occurred in practice. It seemed to Dr. Crowe that there were several reasons for these failures, and that if steps were taken to improve the technique there was no reason whatever why the vaccine treatment of rheumatism and arthritis should not prove to be a brilliant success.

The causes of failure were, first, that staphylococci had never been recognised as being of importance in these conditions. Secondly, that the streptococci were an extremely diverse group, members of which were not capable of differentiation by ordinary methods. Many of these were so delicate that they required very special media for their cultivation. Also they died rapidly on exposure. These facts accounted for the inefficiency of so many streptococcal vaccines prepared in clinical laboratories. Once recognised, however, these difficulties could quite easily be surmounted. Thirdly, rheumatic patients during treatment might suddenly become sensitive to vaccine. If this were not recognised failure often resulted. Fourthly, there was a mistaken idea that reactions were beneficial. Nothing could be further from the fact. Much smaller doses, therefore, had to be given than those usually employed. Lastly, it had not been sufficiently realised that treatment must be prolonged and most persevering. For these various reasons, then, vaccine treatment had not often given satisfactory results.

The Practice of Vaccine Treatment.

As in all other special lines of treatment experience was required. The speaker suggested that practitioners should take simple cases of mild rheumatism and treat them with stock vaccine. Panel practitioners had an excellent opportunity for doing this. After a certain amount of experience more difficult cases would gradually be undertaken, and finally even the most chronic cripples might be brought into the net. Until plenty of experience had been gained it was inadvisable to give vaccines to acute or subacute actively advancing cases, as in these, uninformed and routine treatment might do great harm.

The question of diagnosis was of importance, because, the disease usually called rheumatoid arthritis often proved difficult to treat when definitely established, but was as a rule easy if treatment was undertaken in its early stages. It was of extreme value, therefore, to be able to recognise the earliest signs and symptoms of the disease. These, it must be remembered, were often superimposed on those of long-standing osteoarthritis. The most significant sign was nuchal crepitus, in the absence of which *M. deformans* infection and therefore rheumatoid arthritis could definitely be excluded. General

symptoms often appeared very early. Paræsthesias (tingling and numbness) might be noticed. Weakness of muscles, especially of the forearms and lower limbs with consequent dropping of the metatarsal arch, were amongst the earliest obvious signs. Small joints were first attacked. A pathognomonic sign was a hypothenar flush. The speaker suggested that these various signs and symptoms might be called the rheumatoid stigmata.

Preventive Treatment.

The question was propounded as to whether it might not be possible to prevent arthritis and the severer forms of fibrositis which were the cause of so much industrial disability. Dr. Crowe believed that this was not only possible but was easy. The three essentials were early treatment by the general practitioner, clinics where the poorer classes could come and receive treatment for nominal fees, and lastly, an educative propaganda inculcating early treatment. In this last clinics themselves would play a very important part. But before these steps could be undertaken it was necessary that the general practitioner should acquire that facility in the treatment which alone would lead to success.

Dr. Warren Crowe's address was followed by a discussion.

MANCHESTER MEDICO-CHIRURGICAL AND OBSTETRIC SOCIETY.

AT a meeting held on Oct. 27th, with Mr. A. C. MAGIAN in the chair, Mr. R. R. KERR read a paper on

Abdominal Tuberculosis in Children.

Surgical tubercle in all its forms, he said, is known to be exceedingly common in Scotland. In the north of England it is by no means so obvious, but in Lancashire, where the climate is hardly ideal for the young of the human race (or for the middle-aged for that matter) it is rare not to find caseous glands in the mesentery in the course of the systematic examination carried out in a modern laparotomy. It is clear from this that tuberculous infections of the abdomen are not only very common, but also that in most instances complete recovery occurs without any symptoms having been noticed. In the great industrial community the way is probably prepared for the disease, not only by the damp and sunless climate, but by the weakening effects of rickets, infantile malnutrition, and absorption from septic teeth—conditions which have been tackled seriously and with a measure of success within the last generation. The problem of the mother who has to follow whole-time work in mill or factory is, of course, still to be solved.

In children, said Mr. Kerr, tuberculous infection usually reaches the bowel in milk or diseased meat. Here it may attack the lymphoid tissue and the Peyer's patches which lie in the lower end of the ileum, setting up localised ulcers, or it may be picked up by this lymphoid tissue and passed through to the mesenteric glands; this appears to be by far the commonest process. At other times it settles in or around the appendix, another lymphoid organ. From the ulcers in the intestines or the infected glands the process may spread to the peritoneum, setting up one of the forms of tuberculous peritonitis. The ulcers of the ileum may simply remain localised to the Peyer's patches in the mucous membrane of the bowel, tending to spread in a circular way around the gut and giving rise to diarrhœa, indefinite discomfort, and wasting. If they heal, the cicatrices tend to form ring strictures and may cause obstruction, but much more often the disease spreads through the bowel, setting up inflammatory fibroses around and matting and adhesion of adjacent coils—the condition known as hyperplastic tuberculosis, in which one or more definite masses can be felt through the abdominal wall. This condition has to be diagnosed from appendicitis and chronic appendix abscess, and it does not require much imagination or much experience in surgical work to know that the two are very frequently mistaken for each other. The tuberculous appendix may appear simply as an inflamed and thickened organ or its surface may show tubercles; but more commonly it is associated with tuberculosis of the cæcum, mesenteric glands, and neighbouring peritoneum, and the whole together may form a matted mass of infiltrated tissue, with small or large abscesses in the later stages. Tuberculous appendicitis often gives rise simply to a vague discomfort in the right iliac region, probably associated with malaise and wasting, and usually without the acute signs which characterise ordinary appendix inflammation.

When the disease affects the peritoneum, continued Mr. Kerr, this membrane becomes irritated and inflamed and exudes a varying quantity of clear rather yellowish fluid which later may become sero-purulent. The peritoneum itself often shows large numbers of small miliary tubercles and tends to become thickened and lose its normal lustre. As in all granulomata there is overgrowth of tissue; the mesentery becomes thickened, dull, and inflamed; its glands are enlarged and often caseous, and the intra-abdominal structures adhere to each other and to the abdominal wall sometimes in such a way as to obliterate the abdominal cavity. All degrees of these changes take place in different cases and the clinical appearances accordingly vary tremendously. For ease of description they are usually depicted in three groups—the ascitic, the fibrous, and the caseating or ulcerating; but these are not clinical entities, and one type merges into another, different symptoms predominating in different cases. In the ascitic form there is a large amount of fluid, usually pale yellow in colour; the abdomen is distended and the child is wasted. This form of the disease is always serious and often rapid in its course, the progressive wasting being accompanied by hectic fever, vomiting, constipation, and sometimes diarrhœa. In the fibrous form there is much matting of the intestines to one another and to the abdominal wall and little or no fluid. The omentum becomes drawn up and thickened (rolling of the omentum), sometimes forming a definite and easily palpable elongated tumour across the abdomen above the umbilicus. The patient in this type is usually not so ill as in the first, and there is a distinct tendency to recover. In the caseating type, in its advanced stages, the abdomen is simply filled with matted intestine and caseous granulomatous material in which small or large abscesses occur. These become secondarily infected from the bowel, ulcerate into the bowel or point through the abdominal wall, forming intractable sinuses and fæcal fistulæ, until the patient eventually dies of exhaustion, usually after a long and miserable illness.

The surgical treatment of this disease, said Mr. Kerr, is by no means entirely satisfactory, and depends largely upon each case being taken absolutely on its merits and also upon the experience and insight of the surgeon. Operation is inadvisable in the early stages where the disease is only suspected or where the diagnosis is reasonably certain by reason of continued malaise, slow or progressive wasting, possibly slight evening rise of temperature with indefinite abdominal discomfort, constipation, and occasional vomiting, combined with an abdomen slightly distended or giving the impression of irregular thickenings. The child should be treated on general lines with rest, open air, nourishing and easily digested food, and carefully graduated exposure to natural or artificial sunlight. Where there is definite ascites, however, it is always advisable to explore the abdomen, let the fluid escape, and deal with any obvious focus found. It is always wise in these cases to remove an inflamed or thickened appendix and to operate specifically for this if the diagnosis can be made. Pointing abscesses should be opened, warning being given of the danger of chronic sinuses and fistulæ resulting. For some curious reason a proportion of these patients do very well after operation, although nothing has been done beyond allowing the fluid to escape.

Where the fibrous changes predominate, said Mr. Kerr in conclusion, operation must usually be

absolutely inadvisable, but even here there are unlooked-for exceptions. About six years ago he was consulted about a youth who was in the advanced stage of this disease. He was wasted and cachectic, and his abdomen was full of irregular masses. He was advised strongly against any operation and sent to the seaside in good weather and conditions, but about two months later his condition had deteriorated and Mr. Kerr's hand was forced, rather against his judgment, by an attack of obstruction. On entering the abdomen with difficulty he found nothing but firmly matted bowel, everywhere adherent to the abdominal wall, and caseous masses of glands. The abdomen was closed and the parents told that the boy could hardly live for more than a few days. From that hour he proceeded to make a recovery which clinically appeared to be complete in about a year, and has remained so. Mr. Kerr found it difficult to draw any moral from this.

Following the reading of Mr. Kerr's paper there was a discussion, in which many members of the Society took part.

JAMES MACKENZIE INSTITUTE FOR CLINICAL RESEARCH, ST. ANDREWS.

AT a meeting on Oct. 19th Sir HUMPHRY ROLLESTON read a paper on

High Blood Pressure from the Clinical Aspect.

He raised particularly the question whether or not a rise of blood pressure, per se, apart from causal toxic factors or the resulting arteriosclerosis, gave rise to symptoms of ill-health. It was not an uncommon experience, he said, to detect blood-pressure readings higher than the average in individuals who were entirely free from symptoms, and harm might result from too energetic measures adopted for lowering these pressures. Certain hypersensitive subjects, however, might conceivably manifest symptoms as the result of the heightened blood pressure alone. Libman had described a simple means of estimating individual's response to afferent stimuli, and ascribed angina *sine dolore* to the patient being hyposensitive. But to apply this explanation to high blood pressure would necessitate the assumption that in the early stages persons with high blood pressure were hyposensitive and became hypersensitive; possibly as high blood pressure was often due to protein derivatives, the hypertensive individual's nervous system might at some stage become sensitised by the protein bodies and so allow symptoms due solely to the high blood pressure to appear. On the other hand, F. M. Allen and others considered that high blood pressure was always due to underlying structural changes either of the kidney or of an arteriosclerotic nature. Bordley and Baker had shown by post-mortem findings that arteriolar sclerosis in the medulla oblongata was definitely associated with high blood pressure. But it was difficult to believe that such a change could underlie those cases in which a high pressure persisted for years with no advance and without interference with health.

Sir Humphry Rolleston also referred to the possibility of arterial spasm in this connexion, and spoke of work done by Draper on the constitutional make-up of subjects of high blood pressure. Finally, he considered seriatim the various symptoms commonly associated with high pressure cases in their early stages and questioned whether or not these occurred in the absence of definite chemical or structural changes. The tendency to hæmorrhage—nasal, intestinal, retinal, or cerebral—was probably dependent not on the pressure alone, but on vascular degeneration associated with it. Probably each common symptom considered could be explained by the presence of some factor other than the rise of pressure.

In the paper and the discussion which followed, the importance of the distinction between the rise of pressure itself and the associated degenerative changes was emphasised.

Reviews and Notices of Books.

A NINETEENTH CENTURY TEACHER.

John Henry Bridges, M.B., F.R.C.P. By his Niece, SUSAN LIVEING. With a Preface by Prof. L. T. HOBHOUSE, and an Introduction by Prof. PATRICK GEDDES. London: Kegan Paul, Trench, Trübner and Co., Ltd. 1926. Pp. 262. 10*s.* 6*d.*

John Henry Bridges was the son of the Rev. Charles Bridges, vicar of Old Newton in Suffolk, a man of views as uncompromisingly Calvinistic as those held by the naturalist, Philip Gosse, so brilliantly set out in "Father and Son." The atmosphere of the vicarage was repressive; in Miss Liveing's amusing words "the responsibility for their children's souls lay heavily on the parents, and one is left wondering how the roots of grace took hold at all, so sedulously were they pulled up to look for signs of growth." Luckily for John Henry Bridges, his uncle, the Rev. Charles Torlesse, vicar of Stoke, was of a different school, and when staying with the Torlesse family the boy's character had opportunities to open up. In 1845 Bridges went to Rugby under Tait, later Archbishop of Canterbury. Here he did well, and in 1851 proceeded to Wadham College, Oxford, with a scholarship. At Oxford he came particularly under the influence of Richard Congreve, a man of advanced opinion of the sort that would have filled Bridges's father with horror, and among his fellow undergraduates were two brilliant men, Edward Spencer Beesly and Frederic Harrison, both of whom counted in their friend's development. Congreve was a friend of Comte and a passionate advocate of his teachings. These three young men, together with George Earlam Thorley, who afterwards became Warden of Wadham, formed a small brotherhood which came to be the foundation of the Positivist Society in England. At this juncture fate dealt hardly with Bridges, he was expected by all to obtain a First Class in Greats, but by one of those turns of fortune, of which the Oxford class lists can show curious examples, he was placed in the Third Class, although one of the examiners said that he was "the ablest man in." This reverse shaped his future. He could no longer stay permanently in Oxford; he was intended for Holy Orders but felt that they were not for one with his religious opinions, and he turned to medicine, assuming, apparently, that a career of scholarship had been closed to him. One year remained during which he was a scholar of Wadham and he stayed in Oxford reading mathematics and science, and writing the Arnold Prize Essay entitled "The Jews in Europe During the Middle Ages," which gained him a Fellowship at Oriel College. But this success did not lead him to change his intentions of becoming a physician.

In 1856 he entered at St. George's Hospital, where he did brilliantly, taking the M.B. Oxford and the M.R.C.P. in 1859. In the following year he married his cousin, Susan Torlesse, and having previously determined to emigrate to Australia, they sailed in March, 1860, and on landing at Melbourne in June, Bridges started to practise. Then fortune dealt him another blow, for by the end of December Susan Bridges lay dead from typhoid fever and her striken husband returned to England bringing her body with him for burial at her father's church at Stoke. Keeping to the purely medical side of his life, Bridges now, and mainly for family reasons, determined to settle at Bradford and practise as a physician. He was elected almost immediately physician to the Bradford Infirmary and plunged into the industrial and sanitary problems of the day, which certainly were crying out for solution. They were briefly set out by Charles Kingsley at this date, in his lectures "The Roman and the Teuton," in which, speaking of the loss of life caused by the barbarian wars, he says "we have no right to blame those old Teutons, while we are killing every year more of Her Majesty's subjects by preventable disease

than ever they killed in their bloodiest battle." For seven or eight years Bridges laboured at sanitary difficulties and strove to combat the distress caused by the cotton famine of 1863 and the prevailing lack of decent housing. In 1869 he married as his second wife Mary Hadwen, whom he had known from a child, and in the same year he was offered the post of factory inspector for the North Riding. He held this post for a few months only, but this short time was enough to assure him of the evils of female labour in factories, and to win for his position as a sanitarian and reformer wider notice. Goschen asked him to act as locum tenens for one of the medical inspectors of the Poor-law Board, and when this officer's illness prevented his return the post was offered to, and accepted by, Bridges. Shortly afterwards Bridges became closely connected with THE LANCET. The scandals of Poor-law relief and the crying need for reform in the management of Poor-law infirmaries had been shown up in our pages in 1866 in uncompromising terms, and Bridges was in close touch with those who wrote the scathing reports. Large improvements were promised, and some were slowly carried out, it being through Bridges mainly that they materialised, for he never ceased by unceasing vigilance, by persuasion, by conciliation—if driven to it by stern insistence—to see that the reforms were carried out. For 22 years he laboured at a grand task of reconstruction, and when he resigned his post in November, 1892, he had lived to see as the fruit of his labours five fever hospitals in London and excellent Poor-law infirmaries, while the election of women guardians was established. It was a great record.

Bridges died in 1906 after occupying the last 14 years of his life partly in working for Positivism and partly in literary pursuits. His edition of the Opus Majus of Roger Bacon was undertaken at the request of the Clarendon Press, and he had every qualification for the work except one, and that an important one —namely, expert knowledge of palæography, giving ability to decipher manuscripts. During the progress of his edition a new MS. was discovered, of which he was left unaware, and as he failed to decipher correctly certain MSS. to which he had access, he was charged, on the appearance of the work, with being slipshod and unscholarly. He met the charge as a man of his honesty and passionate love of truth would. He had the new MS. photographed and transcribed by an expert palæographer, and brought out a new edition of his work with all necessary corrections. This was published in 1900, and was in every way worthy of the great Franciscan, but the errors entailed upon Bridges both labour and vexation, and he felt the shock to the end of his life.

We confine this notice to the medical and scientific aspects of Bridges's career, but he was equally well known as a preacher of Positivism, as an ardent leader against oppression in any form, as a burning critic of his country's political attitude on more than one occasion, and as a passionate advocate of the under dog in every form.

MODERN TREATMENT OF GENERAL PARALYSIS.

Der heutige Stand der Behandlung der progressiven Paralyse. By Dr. LADISLAUS BENEDEK, Professor in the University of Debreczen, Hungary. Berlin: S. Karger. 1926. With 25 illustrations. Pp. 219. M.12.

ALTHOUGH the title of this book indicates its concern with the treatment of general paralysis, we find chapters on ætiology, pathology, pathogenesis, on hyperergic reactions in the disease, taking up, perhaps, a quarter of its pages. The treatments examined are those by injections of immune serum, by infection (paraspecific therapy), and by direct (intralumbar and other) methods. In regard to the first of these, the following figures are given: of 63 patients thus treated, 6 improved, 15 became worse, 19 remained unchanged, and 23 died. Under the second category are discussed the techniques and results of tuberculin, vaccines, sodium nucleinate, phlogetan, injections of milk, and malaria. To the last of these considerable attention is given; the use of the spirillum of recurrent fever is also examined. The problems associated with the manner of action of paraspecific therapy receive consideration. Finally, the numerous modifications of salvarsan therapy are investigated. After each chapter excellent bibliographical references are furnished. The treatment of general paralysis is in a state of flux; this useful volume discusses not only modern therapeutic methods but also those now almost obsolete and of little more than historical interest. On the other hand, it is equally possible that the vogue of the malaria method will fade when a true specific therapy is attained. For the moment it seemingly holds the field, although the use of tryparsamide is also receiving support.

NERVOUS ANATOMY.

Les Noyaux Gris Centraux et la Région Mésencéphalo-sousoptique. By Ch. FOIX and J. NICOLESCO. Paris: Masson et Cie. 1926. Pp. 582. Fr.125.

WE have nothing but praise for this fine contribution to nervous anatomy, which is, indeed, worthy to take its place as a supplement to Dejerine's famous "Anatomie des Centres Nerveux." Superbly illustrated, it fills a definite lacuna in the literature, for the ever increasing study of the pathological and clinical aspects of the basal ganglia renders exact knowledge of their anatomy indispensable.

A description of the general anatomy of the basal ganglia and the regio subthalamica is followed by a minute study of serial sections, cut in various directions, and this in turn by a synthetic consideration of each organ separately and its connexions. There is an appendix on the pathological anatomy of Parkinson's disease.

The volume does the greatest credit to its authors, the printers, and publishers; it represents French neuro-anatomy at its highest level of lucidity and erudition.

THE DISPENSATORY OF THE UNITED STATES OF AMERICA.

Twenty-first edition. Edited by HORATIO C. WOOD, jun., M.D., and CHARLES H. LAWALL, Ph.M., D.Sc., Phar.D., with the assistance of H. W. YOUNGKEN, J. F. ANDERSON, and IVOR GRIFFITH. London: J. B. Lippincott Company. 1926. Pp. 1792. 65*s*.

THE general form and mode of presentation of this immense work of reference are the same as in the previous 20 editions, but the pharmaceutical progress of the last eight years has involved a large amount of revision and rewriting. The new U.S. Pharmacopœia has officially recognised 33 new drugs, and many other new remedial agents have been introduced. The International Formulary being now a legal standard in most parts of America, the drugs contained in it have been transferred to the official section of the dispensatory. Careful pruning and condensation have avoided any increase in the size of a book already, as the editors admit, somewhat unwieldy in a single volume. Translations of metric into apothecaries' measure and of Centigrade temperature into Fahrenheit have accordingly been dropped in the hope that they will no longer be found necessary by a large proportion of readers, but the double system is continued in the case of doses, for it appears that practically all prescriptions in America are written in apothecaries' measure. Copious bibliographical references are designed to unlock the door of the past to those who wish to trace the history and development of some phase of pharmacy. The text is given of the Food and Drugs Act and of the Harrison Narcotic Act, and then follow in alphabetical order the descriptions of official drugs, some account being included in each case of the commercial history and varieties, physical properties, constituents, impurities, adulterations, and

uses. This book is the standard work of reference for pharmacists in the United States and will prove a mine of information to their colleagues and all who are interested in drugs and drug preparing in other countries.

SEX IN MAN AND ANIMALS.

By JOHN R. BAKER. London: Routledge and Sons. 1926. With 22 figures. Pp. 175. 7*s.* 6*d.*

PEOPLE nowadays think and talk so much more frankly and openly about sex than they used to that it is well, as Prof. Julian Huxley says in his preface, that they should have some accurate knowledge of the fundamental facts. In this book Mr. Baker has given a plain and very clear account of the mechanism and significance of sexual reproduction, adapted, as he hopes, for biological and medical students as well as for the general public. In successive chapters he exposes the advantage of sexual propagation, sexual selection, sex chromosomes and hormones, abnormalities of sex, the sex ratio, the control of sex, and sex behaviour. The accuracy of his facts is vouched for by Prof. E. S. Goodrich and Prof. J. Huxley, and in a small space he tells an interesting tale in a way which will probably be intelligible to a serious reader without any technical training. Rather unfortunately, we think, Mr. Baker has not been able to resist the temptation to point what he takes to be the morals of it all and, especially in its later parts, the book wanders over the widest fields of speculative psychology and dogmatic sociology where his statements are naturally of a different order of validity from those which describe the results of experimental biology. In what he says, for instance, about over-population, contraception, and agricultural life in the Dominions (p. 168) he does not seem to realise that there is no evidence of a serious kind that children of small families grow up into better citizens than children of large families; that such is the case seems a natural a priori assumption, but it is no more than that. However, where Mr. Baker is weakest his readers will be strongest and will form their own opinions. These will be more likely to be correct if his cytology and physiology have been properly apprehended.

JOURNALS.

BRITISH JOURNAL OF OPHTHALMOLOGY.—To the August issue Prof. O. Berner (Oslo) contributes a highly technical paper entitled "Studies in the Peripheral Relations of the Musculus Dilatator Pupillæ." The existence of this muscle, long doubted, is now established, but its attachments have never hitherto been defined. The paper should be read in relation to the different theories which are held of the functions of the circular fibres of the ciliary muscle.—C. A. Clapp (Johns Hopkins Medical School) gives drawings of new-formed vessels in the vitreous of a syphilitic patient.——In the September issue R. C. Davenport reports on the cases of glioma retinæ treated at Moorfields during the years 1915–24. There were 27 treated during this period. In 17 of them the end-results and histories were sufficiently certain to give figures. The known cures—i.e., survivals for three years without recurrence—were 7, but in one case recurrence in the second eye took place about 14 years after excision of the first eye. Progress was then so slow that it was four years before the second eye was excised in 1918. It is remarkable that in this case the patient made a good recovery and is still alive. Another report on the after-results of corneo-scleral trephining for glaucoma by the same author is even more interesting. The paper analyses the results in the case of 405 eyes trephined for primary glaucoma. Of these 80 per cent. were apparent successes and only 4·5 per cent. complete failures. The point which remains most in doubt as to this operation is that of late infection. In all 14 cases of "late" infection were treated at Moorfields during the years 1919–24, and in eight of these it was clearly an infection via the trephine hole. The majority of the cases occurred a few months after operation—one as late as seven years after. In only two cases was the infection so severe as to call for evisceration. Mr. Davenport opines that late infection, while a serious if not very frequent misfortune, is hardly the bogy it is often made out to be by some who even call for the total abandonment of the trephine operation.—— The October issue is occupied by a long communication from W. S. Duke-Elder on the ocular circulation, its normal pressure relationships and their physiological significance. Incidentally, he has some hard words to say of any form of tonometer as an instrument of precision. Its only use, he says, is confined to the comparison of the two eyes of the same individual at the same time, or of the same eye at different times. This, however, is precisely the way in which the instrument is generally employed. For this reason he condemns P. Baillart's method of measuring the intra-ocular arterial and venous pressure and has devised a method of his own which he describes. Experiments were carried out in the Department of Physiology and Biochemistry in University College, London. It is demonstrated that the pressure in the retinal arteries is about 75 mm. Hg in the cat, that the pressure in the intra-ocular veins is in all circumstances greater than the intra-ocular pressure, but, under conditions of raised intra-ocular pressure, the pressure in the venous exits may fall below the chamber pressure. The capillary pressure is very variable and has no direct relation to that of the arteries. The relation of the vascular to the intra-ocular pressures is compatible with the theory of the formation of the aqueous by a process of dialysis from the blood, so that the hypothesis of a secretory apparatus in the ciliary body is unnecessary. The circulatory conditions lead to the expectation that the dialysation of the intra-ocular fluids would occur *from* the blood stream mainly, but not entirely, through the vessels of the ciliary body and iris, and *to* the blood stream mainly, but not entirely, through the canal of Schlemm. Incidentally, the assertion of Thomson Henderson that the circulus arteriosus major of the iris is really venous is combated. The article, to which is appended a copious bibliography, is an important contribution to the physiology of the eye.

THE RASSEGNA INTERNAZIONALE DI CLINICA E TERAPIA (Naples) for August, 1926, contains an interesting original contribution by Prof. V. Tramontano and Dr. F. Pansini on Multiple Neurofibromatosis, a syndrome described by Recklinghausen in 1883 and generally associated with his name. After a résumé of the work done by other observers the authors describe a typical case under their care with coloured illustrations of the microscopical appearances, which show that the new tissues are composed of elements with large clear round or oval nuclei, and arranged in parallel bundles which sometimes assume a spiral form. Changes in the endocrine glands were not found. These observations point to the conclusion that Recklinghausen's disease is due to embryogenetic changes in the tissues which, stimulated by various causes, most frequently toxic, proliferate and determine the morbid process.—Dr. R. Calvanico in another article describes the histological changes in transplanted ovaries in animals. Although the follicular elements completely disappeared after an interval of 40 days, the interstitial elements did not become sclerotic, but contained many cellular elements which suggested a permanence in specific capacity. In proof of this he describes a case in which a healthy ovary was transplanted from one woman into another, who at the age of 25 years suffered from primary amenorrhœa and remained sterile after five years of marriage. The operation was so far successful in that a metrorrhagia occurred at monthly intervals accompanied by turgescence of the breasts and lacteal secretion.—Prof. L. Castaldi contributes a synthetic review on the problem of determination of sex.

THE LANCET.

LONDON: SATURDAY, NOVEMBER 13, 1926.

EPILEPSY AS A DEFENCE.

MEDICAL and legal views of criminal insanity are notoriously unreconciled. The doctors feel that the law courts err in adhering to obsolete tests of mental disease; they know that, long before actual delusions or open signs of insanity manifest themselves, there may be symptoms of a morbid condition affecting the patient's mental activities, and that the early symptoms and the final delusions, mania, melancholia or dementia are merely different stages in one disease. On the other hand, the lawyers answer, in terms which find expression in the Atkin Committee's report: "We do not profess to define disease of the mind, but only to define the degree of mental disease which shall be allowed to negative criminality; this is as much a question of law as the question at what age a child is to be deemed criminally responsible." This difference between the medical and the legal outlook is frequently illustrated, and especially in murder trials, where, since a conviction for murder entails the death penalty, every possible point must be taken for the defence.

A fresh example occurred at the Herefordshire assizes last week upon the indictment of CHARLES HOUGHTON for the murder of two ladies named WOODHOUSE by whom he was employed as butler at Burghill Court, near Hereford. The prosecution alleged that HOUGHTON, a man of 45, had been in the service of the WOODHOUSE family for 22 years and was given notice of dismissal last September because he had taken to drink; next day, after attending family prayers and serving the family breakfast, he shot them and was presently found in his bedroom with his throat cut. A suggestion of epilepsy was made during the cross-examination of Dr. VINCENT SHAW, who was a witness for the prosecution, but Dr. SHAW declared that the accused seemed to be perfectly normal. For the defence the prisoner's sister stated that between the ages of 7 and 11 HOUGHTON had fits which caused him to foam at the mouth. Dr. CYRIL FRANCIS, another witness for the defence, said he had examined HOUGHTON the previous day, when the prisoner seemed not quite normal; the symptoms he found pointed to epilepsy. Dr. FRANCIS expressed the belief that there might be a possibility that HOUGHTON had lost his mental control. During the giving of this evidence Mr. Justice RIGBY SWIFT is reported to have twice interposed the question, "Are you prepared to swear that in your opinion he was in fact so insane as not to know what he was doing?" Dr. FRANCIS was unable to put the prisoner's case so high, and Dr. JAMES BELL, medical officer at Gloucester prison, stated on the other side that in his opinion HOUGHTON had shown no signs of insanity, mental disease, or epilepsy, nor did he think that HOUGHTON had had an epileptic fit on the day of the shooting. HOUGHTON was found guilty on the first indictment of murdering one of the two ladies; he was sentenced to death, and the further indictment in respect of the second alleged murder was not proceeded with.

It may be recalled that one of the Atkin Committee's recommendations was that provision be made under departmental regulations for examination of an accused person by an expert medical adviser at the request of the prosecution, the defence, or the committing magistrate. Has this been done, or is the matter left in abeyance like the other recommendations made by the Committee?

NARCOLEPSY.

"The disease I am about to describe is characterised by the occurrence of attacks of irresistible sleep without apparent cause, and curious attacks on emotion in which the muscles relax suddenly so that the victim sinks to the ground, fully conscious, but unable to move."

THIS almost dramatic sentence forms the opening paragraph of a paper on Narcolepsy by Dr. W. J. ADIE in the October issue of *Brain*. In it the whole description of the malady is crystallised, for Dr. ADIE rightly contends that the term "narcolepsy" is best confined to the condition—with peculiar and unmistakable features—of which his article treats. His description of the characters of the disease is based upon eight cases from his own observation, supplemented by some 15 published reports, and it will undoubtedly establish the condition as a clinical entity with this label. Narcolepsy, as thus defined, is more common in the male sex; it usually begins between the ages of 11 and 35 and persists unabated throughout life. REDLICH first drew attention to signs of ductless gland disorder in some of the cases—a small pituitary fossa, slight acromegalic signs, obesity, delayed sexual development, or periods of amenorrhœa being occasionally observed. Otherwise the patients are to examination physically and mentally normal. In most cases two kinds of attacks occur: either the patient is overcome by sleep, or, usually as a result of some emotional disturbance, the muscles become flaccid and powerless. These Dr. ADIE names "sleep attacks" and "cataplexy" respectively. The former nearly always appear first and may precede the latter by a year or more. The attacks vary greatly in frequency, but usually occur daily, and each may last from a few seconds to 15 minutes or even more. There is a certain constancy in those of each individual. They may occur not merely when conditions are conducive to sleep but when they are the very reverse—in the midst of an interesting conversation, while cycling or riding, during bombardments and even on listening-post duty. Many patients know when an attack is coming on, but, though they may delay it, they cannot prevent the onset of sleep; on the other hand, any slight stimulus from without may dispel the sleepiness at once and completely. The sleep of the attack is in every way similar to natural sleep. The cataplectic attacks are brought on by emotion, usually by laughter; "when I laugh I fall down." In these seizures, as a rule, the patient merely feels limp, falls flaccid, and regains control of himself after a few seconds, but occasionally the cataplectic attack may end in sleep. Naturally enough, many such attacks are mistaken for petit mal, and some are even diagnosed as chorea. Dr. ADIE takes some pains to show that the two kinds of attack are essentially the same, the cataplectic attack corresponding to the aura of the sleep attack and being in fact merely a slighter form of it. The feeling of powerlessness is merely an exaggeration of that helplessness or inability for action which may overcome normal people or animals under strong emotion—e.g., with laughter, or during fear or horror. "But our patients," he says, "so far overstep the arbitrary limits of the normal that we are justified in saying that they suffer from disease."

The diagnosis has to be made from epilepsy, pyknolepsy, and hysteria, and from certain conditions such as pituitary or other cerebral tumour in which excessive somnolence may prevail. From epilepsy the main diagnostic difference is that cataplectic attacks are brought on immediately by a recognisable exciting cause—namely, emotion—whereas attacks of epilepsy come on without apparent cause; in ruling out hysteria reliance may be placed on the absence of undoubted hysterical manifestations and the failure of every kind of suggestion to banish the attacks.

Dr. ADIE is most interesting, however, when he discusses the theoretical considerations to which this disease gives rise, and co-relates the phenomena of narcolepsy with those observed in animals by PAVLOV during his study of sleep. The matter is closely bound up with the study of the so-called conditioned reflexes. We can distinguish between reflex activities with nervous connexions present at birth, and associated reflexes which appear during life; if indifferent stimuli frequently accompany a stimulus which evokes an inborn reflex, these stimuli by themselves soon begin to evoke the same inborn reflex by "association." PAVLOV calls the inborn reflexes "unconditioned" and the acquired reflexes "conditioned." Conditioned reflexes may be inhibited or delayed (internal inhibition). From the beginning of his researches on conditioned reflexes PAVLOV was greatly hindered by somnolence and sleep which overcame his animals during the experiments. For example, it would happen that after a good conditioned reflex had been established, the animal became somnolent or fell asleep during the time that the conditional stimulus was active. In one instance food followed the stimulus in ten seconds and the reflex secretory and motor responses of the animal during those ten seconds were very active. But when food was withheld for 60 seconds the dog became sleepy during the waiting period, the conditioned response disappeared (was inhibited), and the dog that had never slept in the experimental stall before fell asleep every time the stimulus was repeated. From variations of many such experiments PAVLOV reached the conclusion that sleep and internal inhibition of reflexes were essentially the same process—inhibition being a partial and strictly localised sleep confined to a small area of the cortex—while sleep was inhibition which had spread throughout the cerebral hemispheres and to subcortical centres. If we wish to limit inhibition and prevent it passing into sleep we must produce new points of excitation in the cortex by using stimuli of a different kind.

In the attacks of narcolepsy every gradation is seen between slight and local cataplexy and profound and prolonged sleep. If, as appears likely, the former is a result of inhibition of cortical processes, then the sleep in the other cases must also be due to inhibition. PAVLOV'S conclusions thus receive support from the phenomena of narcolepsy. On the other hand, some features of narcolepsy become intelligible in the light of his experimental findings. Apparently, attacks in narcolepsy are favoured by a lack of extraneous stimuli and, secondly, by monotonous stimuli. In PAVLOV'S dogs repeated stimuli, even though painful, produced sleep with certainty if no dissimilar extraneous stimuli reached the animals. The receptive point on the cortex apparently became fatigued; it slept, and the inhibition spread to produce general sleep. The same seems to occur in the narcoleptic patient. Again, it was difficult to understand at first why patients were unable to resist sleep and yet could almost always be wakened with extreme ease. PAVLOV'S results supply the explanation: the inhibition was dispelled at once and completely by a fresh excitation of another kind. Dr. ADIE submits that all the attacks in narcolepsy are due to inhibition, whether they take the form of "tone loss attacks on emotion" or of frank sleep. The explanation is ingenious and satisfying and in accordance with experimental work. The indications are that such a physiological disturbance arises from a disorder of the pituitary or of structures in the 'tween brain which are associated with it.

BIRTH CONTROL INSTRUCTION BY PUBLIC AUTHORITIES.

IN the last annual report of the county borough of Croydon Dr. H. P. NEWSHOLME comments upon the desirability of giving official permission to public authorities to instruct poor people in artificial birth control. Two arguments stressed by Dr. NEWSHOLME deserve consideration. (1) He considers that children of large poor families, born at close intervals, gain, from contact with other children of their own age, more than they lose from the physical privations to which they are exposed by the extra financial responsibilities of their parents. (2) Any method of birth control other than that of self-restraint cannot be generally encouraged on account of the "irreparable harm" which the use of contraceptives might cause by "changing the attitude of husband and wife to one another." "I feel," says Dr. NEWSHOLME, "that this, though a difficult matter to define, is a fundamentally important question, and that the basic danger to national life arising from the adoption of mechanical means of birth control on anything like a national scale depends not so much on the risk of a stationary population as on that of a materialistic bias in the national attitude towards sex and marriage." Dr. NEWSHOLME concludes his review with a cautious advocacy of a medically supervised extension of knowledge of artificial birth control to the poor. But he makes two conditions for this proposed official extension. The first is that the selection of medical officers be very carefully made. The responsibilities to be undertaken are so onerous, and their incompetent discharge so fraught with disaster for the community, that only medical men of established discernment and judgment are held to be fit for it. The second condition is that advice be given only when the medical officer has personal knowledge of the home circumstances of both parents, and when he has discussed with them the possibility of applying methods of self-restraint. Dr. NEWSHOLME would have this advice given at the antenatal centres rather than at the child welfare centres.

With Dr. NEWSHOLME'S practical conclusion few unprejudiced medical men to-day would quarrel. A motion embodying the same general conclusions was carried by a majority of votes early this year in so conservative a body as the House of Lords. But the considerations advanced above, which make his conclusion so tentative and conditional, hardly possess universal applicability. His argument that the children of small families suffer from deprivation of healthy contact with children of their own age, while probably being true of Croydon—a relatively well-to-do neighbourhood—does not hold of poorer quarters of London. In these, the playground for the children, in almost all weathers, is the street. Here the child, whether he be an only child or a

member of a large family, is thrown into a more than sufficient contact with children of all ages. The houses and flats of the people for whom the new legislation is suggested are so small, and for the most part so crowded together, that even if each family were restricted to one or two children, these would make, in the streets and the enclosures of the tenement houses, as much healthy contact with children of approximately their own age as the sturdiest educationist could require. But Dr. NEWSHOLME'S argument undoubtedly has weight when applied to the middle classes. The only child of the city worker, living in a semi-detached villa in the suburbs, or even of the wealthier parent residing in a more fashionable part of London, in more cases than not does suffer from the deprivation described by Dr. NEWSHOLME. But it is not primarily for the mothers of these that the medical officer of the antenatal centre would provide the suggested information. The second argument, that the use of contraceptives leads to a loss of mutual esteem between parents, is one which emanates more frequently from the mouths and pens of clergymen than from doctors. Anyone acquainted with the street corners of slums on Saturday nights or on Bank Holidays can picture to himself the scenes that are destined to be enacted between husband and wife when the public-houses are emptied and the homes are filled. If we are concerned with the mutual respect between the slum-dwelling husband and his wife let us discuss it in this connexion after the drink question has first been solved.

There is another aspect of this problem which has been omitted from consideration by Dr. NEWSHOLME, though it has considerable medical importance. The sale of contraceptives which are bought and fitted without any kind of medical advice or supervision has been conducted among the middle classes for a considerable time past. It is beyond discussion that the promiscuous buying and unsupervised adjusting of pessaries has been responsible for not a little genital disease, and probably also of sterility. Insufficient distinction has been made by medical men between the harm caused by contraceptives thus promiscuously acquired, and that following from their use after the cervix has been inspected and a pessary of suitable size, quality, and shape has been fitted by a competent doctor. It is to be presumed that these measures would become the routine of the medical officers as they now are at the clinics where information on artificial birth control can be obtained. The indifference evinced until recently in this matter by the medical profession has led to an extensive sale of contraceptives which are inefficient, injurious, and in many cases outrageously expensive. Hitherto the sale has been made chiefly to the middle classes. To-day there are signs that it is being extended to the working classes, where already the practice of abortion in its crudest forms is prevalent enough. There are at present several firms—and not all of them British—bent on selling contraceptives to the English public. Seeing that there is nothing whatever to prevent a woman, whatever her status, from buying these contraceptives, and nothing to hinder her from misapplying and misusing them, it would seem desirable on purely medical grounds that facilities be made available for consultation and supervision, though whether these should be linked up with welfare clinics is not necessary.

Upon the question of birth control many highly controversial statements have been made. In the present circumstances, however, it seems possible to frame two that will command fairly general assent. In the first place, it may be said that birth control, whether by means of contraceptives or by self-restraint, is being practised relatively too much by the upper, middle, and artisan classes, while it is being practised relatively too little by the unskilled labouring classes. Secondly, it may be stated that if birth control is to be practised at all—and many inducements to its adoption, commercial and otherwise, are being brought to bear on all classes—it should be practised under proper medical supervision.

Annotations.

"Ne quid nimis."

THE BEIT MEMORIAL FELLOWS.

FIRST among the problems of post-graduate medical education is the kind of training most suitable for those intended to fill the posts of teachers in medical schools. The experience needed by men who intend to devote themselves exclusively to research on the one hand or to the healing of the sick in their own homes on the other, is easier to arrange. Those acquiring new knowledge, and those anxious to apply that already gained are at opposite ends of the medical pole and there is no special advantage in burdening either class with too intimate a knowledge of the perplexities of the other. Indeed, some hold that the business of research should not be hampered by any sense of the need to achieve immediate practical results, while the dogmatic optimism of the practitioner is often a better tonic when untempered by perception of the futility of arguing from uncontrolled results. Teachers, however, must have an appreciation, if not actual experience, of all branches of medicine, if they are going to help each student to select the activities most suited to his talents. The formation of clinical units in our medical schools was an expression of the desire to secure as teachers of medicine and surgery men who have clinical experience and at the same time have not only been trained in research, but are still active in the pursuit of what is to them the most fascinating of recreations. It is more than a coincidence that the endowment of research fellowships by the Rockefeller and Beit trustees has occurred at the same period as the purely clinical training for hospital teachers has been found wanting. It is essential, if we wish to get full value from such generous endowments, to make known the careers open to those selected to hold these research fellowships. Their after-history is at least as important to medical progress in its widest sense as that of the sufferers from the diseases they are subsidised to investigate, and, happily, not so difficult to ascertain. A valuable pamphlet, just issued by the trustees of the Beit Memorial Fellowships for Medical Research (35, Clarges-street, London, W. 1), gives information not only as to the conditions of value and tenure of the fellowships, the places where research is authorised, and the times and methods of application, for the information of candidates, but also a list of the 108 fellows elected since 1910, with the nature of their authorised research and notes on their after careers. Of the total number 6 are dead and 31 are still holding fellowships, or have completed them only in 1926, so that the fate of some 70 fellows remains to be analysed. Of these 12 (F. Ransom, S. Russ, E. Mellanby, T. R. Elliott, J. A. Gunn, C. H. O'Donoghue, J. McIntosh, A. B. Macallum, E. C. Grey, V. H. Moorhouse, G. E. Nicholls, E. B. Verney) have been elected to fill university chairs in such diverse subjects as pharmacology, physics, medicine, zoology, pathology, biochemistry, chemistry, and physiology; 4 (H. Priestley, D. T. Harris, W. G. Penfield, and H. Goldblatt) are associate or assistant professors respectively of physiology (2), surgery, and pathology, and 13 hold lectureships. Fourteen are attached to the honorary staff of hospitals, and of the remainder the majority hold permanent posts in research institutions, mostly with a substantial list of publications to their credit. The success achieved by so many of the Beit fellows should be an encouragement to those hesitating whether or not to apply for the Fellowship in Tropical Diseases now vacant. Formerly the man who chose after qualification to take a research fellowship instead of a routine clinical or teaching appointment used to take a certain risk, since promotion mostly followed the direct line of demonstrator, lecturer, reader and professor on the academic side, whereas the path to clinical promotion was that of

house physician or surgeon and registrar, followed by a long period of more or less continual presence in the hospital as clinical assistant until a vacancy should arise on the honorary staff. It is this intermediate period of "hanging round hospital"—prohibitive to those without private means—that can now usefully be filled by tenure of a research fellowship. The varied record of achievement of the Beit fellows is a sign that whatever the aspirations of a newly-qualified man or woman, the tenure of such a fellowship is likely to advance them.

LIVE AND DEAD VACCINES.

THE stricter sect of the pharmacologists are apt to say that there are about half a dozen drugs which really have some action which is worth considering, and that a good deal of the rest of the pharmacopœia might well go the way of sarsaparilla. What they mean is that only a few drugs have a definite curative action which is so obvious that it cannot be missed by the superficial observation of a few cases. It is one of the great problems of therapeutics to decide for certain whether the effects of "tonics" and "alteratives" and such like really justify the vast quantities of them which are prescribed and drunk. In their favour is the mass experience of practising medical men; against them is the fact that their use is empirical, and their actions, if any, inexplicable. The pharmacological use of bacterial bodies and of substances derived from them came in under the influence of one of the greatest of modern biological discoveries—the immunological species-specificity of proteids—and it was natural that in the earlier trials this specificity should have controlled the choice of the remedial agent; to try to protect against typhoid fever by injecting dead anthrax bacilli would have been an attempt of almost inconceivable originality. But as Prof. J. McIntosh points out in his presidential address to the Pathological Section of the Royal Society of Medicine, which we printed on Oct. 30th, there has slowly grown up a body of varied observations which show that the injection of any foreign proteid may rouse the body to a response which may be favourable against any infection, and, indeed, against some morbid conditions which are not clearly known to have an infective origin. It is not known why ulcers of the leg should be improved and cured by the injection of the bacteria which find their way into distilled water or by an intravenous dose of boiled milk or by an extra large quantity of any bacterial vaccine. The practice is at present frankly empirical. Prof. McIntosh suggests that these non-specific injections throw the body into a state analogous to the fever due to infection and help the general resistance as a poultice helps local resistance. It may well be so, though much more demonstrative evidence is needed before this explanation can be regarded as wholly satisfactory. Whatever its rationale, however, the method is clearly of some therapeutic value, in some cases, notably general paralysis, of a high order. It is, indeed, an "alterative," as anyone who has experienced protein shock therapy will readily agree. If it were better understood it would be easier to use it more efficiently, and it is of good augury that it should be favourably considered from a point of view where specificity generally reigns supreme.

Prof. McIntosh puts forward other conclusions which are also open to some differences of opinion. He regards the use of living vaccines as a retrograde step, which should be rigorously opposed, having in mind the recent discovery of vaccinial encephalitis, and looking with suspicion on Calmette's advocacy of a live vaccine of attenuated tubercle bacilli. It is possible that a dead vaccine virus may be as efficacious against small-pox as killed rabies virus seems to be, and it is most desirable that every effort should be made to find out whether this is so. But it can hardly be denied that all attempts to protect against tuberculosis with dead tubercle bacilli have failed, and in the face of the importance of the problem it seems a little academic to condemn a method which holds out at least some slight chance of success on theoretical considerations of our ignorance of what might happen. The success, too, with dead vaccines in plague and pneumonia is scarcely as great as one would like; the pneumococcus, indeed, has resisted bacteriology and hygiene with most disappointing success. A return to live vaccines would certainly be a return to an earlier practice; it does not necessarily follow that it would be ineffective or dangerous.

THE INCIDENCE OF CANCER IN AMERICA.

IN a recent issue of the *Bulletin* of the Office International d'Hygiène Publique Dr. W. W. King, of the U.S. Public Health Service, discusses the incidence of malignant disease in the United States of America. It is only since 1900 that complete statistics have been available, but even within the comparatively short period of a quarter of a century cancer has passed from the ninth to the fourth place among the principal causes of death. In 1900 deaths from malignant new growths formed 3·6 per cent. of the total mortality, whereas in 1924 the percentage had nearly doubled, reaching 7·75. An exhaustive inquiry was set on foot some years ago by the U.S. Public Health Department in order to ascertain how far the apparently increased incidence of cancer was real. An analysis of the tables brings out a number of interesting points. Thus, in investigating the cancer mortality-rate in various age-groups, it was found that the increased percentage-rate occurred from the age of 20 to 29 years and upwards, but was most marked from 70 years of age. It is pointed out, however, that, as in other countries, there has been a marked decline in the number of certificates in which the cause of death is "unknown" or ascribed to senility, the greater accuracy of modern diagnosis also being reflected in the drop in the number of deaths ascribed to benign tumours. These and other factors probably account for about 30 per cent. of the increased cancer mortality-rate, the remaining 70 per cent. representing the true increase. With regard to the site of malignant tumours, there is a markedly greater increase in the incidence of cancer affecting certain of the more accessible organs, such as the tongue, breast, or uterus, than in that of less accessible sites, such as stomach or liver, the increase ranging from 65 per cent. in cases of cancer of the female genital organs and 103 per cent. in cancer of the oral cavity, to 51 per cent. in cancer of stomach or liver. The greatest increase of all, however, was found in cancer of the peritoneum, intestine, and rectum, which amounted to 148 per cent. in the 20 years under review. As far as cancer of the breast is concerned, it is the age-group 30–39 years which shows the greatest increase in the death-rate. On the other hand, in cancer of the stomach and liver, which accounts for 36 per cent. of all cancer deaths in the United States, the greatest increase appeared in the age-groups above 40 years. Analysis of the statistics furnished by 34 of the United States and by a large number of towns with more than 100,000 inhabitants shows that, generally speaking, the Northern States have a higher percentage of deaths from cancer than the Southern States. Negro and white races appear to be equally susceptible.

ANGINA PECTORIS.

Angina pectoris was known to Hippocrates and Erasistratus, but Heberden was the first of later physicians to describe it, using in 1768 the name it still bears. Parry first suggested calcification of the coronary artery as a cause, but did not follow up his hypothesis with anatomical proof. Jurine, in 1815, suggested as the cause a neuralgia of the pneumogastric and phrenic nerves, and Latham, in 1846, put forward a theory that it was due to cramp of the heart-muscle. Bernard was the first to produce an attack artificially by nicotine, and later work

has shown that this poison acts on the coronary artery as well as on the splanchnic and peripheral vessels. On the whole, the coronary theory is the one supported by the greatest weight of authority, though the discussion reported on p. 1010 shows that it is not universally accepted. Dr. Hans Kohn has expounded it with a formidable mass of evidence in the monograph[1] which he has just published as part of the vast Brugsch symposium. His conclusions are that angina pectoris is invariably due to stenosis of the coronary artery, and that this is nearly always a result of atheroma, syphilitic infection or endarteritis obliterans. Thrombosis occurs in some cases, but embolism and anatomical anomalies complicate only a very few. Nevertheless, he considers, in a certain percentage of patients the cause is functional; nervous instability and the action of toxins produce angina even if the coronary artery is sound. Very rarely the excitant is a purely anatomical lesion of the extracardiac nerves. He deduces from these data that angina is a disease entity and not a group of symptoms, that there is only one angina, and that "there is no pseudo-angina, but only pseudo-diagnosis." The pain, and its by-product the oppression, arise in the coronary artery and in the ischæmic heart-muscle, The question of whether the ischæmia itself is due to acid deficiency, to excess of the waste products of metabolism, or to physical alterations, and whether the pain thus produced is actually due to cramp of the heart-muscle, Dr. Kohn finds himself bound to leave to other investigators. He explains the sense of annihilation as possibly a product of the disturbance in the autonomic nervous system, a branch of which innervates the coronary artery, but thinks it more likely to be an expression of a momentary stoppage of the heart resulting from ischæmia of its muscle. Everyone is familiar with the distress that accompanies the slightest spasm of the heart, and considering the importance of this organ, it is not surprising that any distress here should reflect itself emotionally as a feeling of imminent death. Death in an attack is a result of the local anæmia. Attempts to alleviate the attack itself must always be directed against the spasm, and in certain cases against secondary failure, and this fact supports the coronary hypothesis. Dr. Kohn's treatise should not be neglected, for although he holds decided opinions he has selected his authorities with scientific impartiality, and, needless to say, with Teutonic thoroughness.

WHAT IS ALLERGY?

ALLERGY, according to the definition of Pirquet, the originator of the term, is the changed power of reaction which the body acquires as the result of infection by a parasite or injection of a foreign substance. Obviously this definition is a very wide one. On the one hand, it will include not only infection by parasites which multiply after entrance into the body but also injection or ingestion of chemical substances which do not increase in amount, but rather break down in the tissues into simpler substances; on the other hand, logically at any rate, the definition will include increased power of resistance as well as diminished resistance or hypersusceptibility, though it is in the latter sense that the term is practically always used. Thus the term allergy tends to become broader as time goes on, and is nowadays so much confused with the term anaphylaxis that it is difficult to know where to draw the line. It would seem to be safest to confine the term anaphylaxis to the definitely specific reaction in relation to protein injection for which the word was originally coined by Richet. How much depends on definition may be gathered from a study of a recent book[2] by Prof. Hugo Kämmerer, of Munich, wherein the author discusses allergy in all its modern significance and in its relation to anaphylaxis. These developments carry us far afield and have a bearing on allergic disposition (constitution), diathesis, predisposition, idiosyncrasy, heredity, and numerous other terms which have hitherto belonged to the vague hinterland of clinical medicine without possessing a clearly defined significance. Allergy will not explain all the questions wrapped up in these clinical phrases, but it is all to the good that an attempt should be made to define their boundaries. This discussion naturally leads the writer to a consideration of various diseases which, he considers, have an allergic basis. The diseases included are urticaria, bronchial asthma, hay fever, angio-neurotic œdema, certain forms of enteritis, migraine, epilepsy, the toxicities of pregnancy, Henoch's purpura, metabolic diseases associated with joint conditions, infectious diseases, and some cutaneous diseases. This list is truly formidable, and the casual reader may think that Prof. Kämmerer pushes his theories too far, but the more carefully the line of argument is followed the more obvious it becomes that there is a case for our consideration. The modern work on histamin, on the vegetative nervous system, and on the endocrines are all dealt with fully, and there is a particularly good critical review of Widal's hæmoclastic crises. Although we may not be able to go all the way with the author in his conclusions, we cannot fail to appreciate the thoroughness with which the material has been investigated and put together. A questionnaire at the end of the book includes no less than 87 questions to be answered in the investigation of the causation of asthma on an allergic basis. Those who wish to follow the subject further will find references and a good subject index in Prof. Kämmerer's book.

SYPHILIS IN GENERAL PRACTICE.

PUBLIC discussion of the problems of venereal disease is a recent innovation; it is only a decade since a leading daily paper acknowledged their existence by admitting the word "syphilis" into its columns. Although, however, the treatment of this disease is being spoken of more and more freely, both inside and outside the medical profession, a discussion at the Royal Medico-Chirurgical Society of Glasgow last week showed that many specialists find that the management of venereal cases by general practitioners leaves much to be desired. As Dr. W. H. Brown remarked in his opening paper, "the key to preventing the ravages that follow syphilitic infection, and the social and family calamities that arise therefrom, is early diagnosis and early treatment. . . . Every genital sore should be looked upon as possibly syphilitic until it has been proved the reverse. No one, however expert, is justified in assuring a patient from one or even several examinations that he has not contracted syphilis." All the speakers agreed on the rarity of the so-called typical Hunterian chancre. Dr. Madeline Archibald said that, out of 400 patients from her routine practice whose blood had been tested, no less than 100 were found to have a positive Wassermann, but only 7 of these could recollect having had a typical primary chancre. Although these figures are perhaps unusual, it is of the highest importance that the first lesion should always be recognised, even when it does not conform to type, and to this end, said Dr. Brown, every patient with a suspicious sore should be kept under observation for three or four months, even if repeated search has failed to reveal the pallid spirochæte. The importance of Wassermann tests in all cases where there are doubtful signs is sufficiently evident. Dr. Archibald pleaded for the early administration of neo-kharsivan, even amidst the routine of a busy practice, provided that the contra-indications are known and observed. In recent syphilis, as Dr. J. Ferguson Smith remarked, the physician's motto should be, "strike early and strike hard." Dr. Brown regards intravenous injection of one of the salvarsan preparations as the sheet-anchor in most early cases. The arsenic should usually be supplemented by mercury or bismuth. Practically every patient, in his opinion, should

receive 20 to 25 injections, despite the demand that such persistent treatment makes upon both patient and doctor. Although this intensive medication admittedly subjects the patient to a risk, he believes that the late results of uncured syphilis are so terrible that this risk must be taken. The urine should be carefully watched, but Dr. Smith considered that albuminuria in untreated secondary syphilis was not an absolute contra-indication to the use of neo-kharsivan. In tertiary syphilis, where the patients are usually older, less infectious, and not such good risks, a milder course of treatment might be sufficient. Nor should the practitioner forget the frequency with which unrecognised syphilis might modify such unrelated conditions as varicose ulcers, ununited fractures or cuts which would not heal. Dr. Archibald enunciated a modification of Colles's law as follows: "The mother of a syphilitic child suffers from syphilis of a latent variety, showing no clinical manifestations of the disease throughout her child-bearing life, with the exception perhaps of a positive Wassermann, but in the absence of treatment tertiary lesions may declare themselves during the post-climacteric period." She pointed out that the primary sore in the female is very difficult to detect, and that the first indication of syphilis in a woman is often the birth of a tainted child or late symptoms after the menopause. She acclaimed the treatment of conceptional syphilis as the most hopeful contribution ever made to public health by the syphilologist. Dr. W. H. Scott said that infants tolerate large doses of arsenical preparations, which may conveniently be given into the scalp veins. Seeing that the liver is practically always affected in congenital syphilis, it was curious that a drug which was markedly toxic to the liver of adults had never been known to produce jaundice in a baby. On the other hand, Dr. O. H. Mavor pointed out that late effects on the reticulo-endothelial and endocrine systems must not be forgotten, and that a certain proportion of supposedly infected children are not really suffering from syphilis, but only give the reaction of the maternal blood. Dr. T. K. MacLachlan said that the older remedies are better for neurosyphilis than the modern ones, the best results being obtained with a mercurial inunction followed by potassium iodide for meningovascular syphilis. Dr. Mavor, however, believed that specific intramuscular medication was undoubtedly helpful in causing the disappearance of bronchitis and cardiac pain, correcting cardiac irregularity, producing a consistent fall in the blood pressure, reducing the size of aneurysms, and increasing the sense of well-being. Dr. Douglas Adams suggested that pyrexial treatment would be more logically employed in the primary stage instead of being deferred until the patient was dying of general paralysis. He pointed out, in common with many other speakers, the urgent need for further investigation into the distribution of the spirochæte, its relation to tissue change, its localisation after the secondary stage, and its cultural and experimental properties. There was general agreement on the need for coöperation between pathologist, specialist, and general practitioner.

AMICABLE SUPERSESSION.

A PRACTITIONER asks for a ruling on the correct ethical attitude under the following circumstances. During a holiday a fellow practitioner and friend (B) saw his (A's) private patients for him. One house which B attended for A wishes B to continue in attendance as his fees are lower than A's. Another patient of A's wishes to go on with B whose evening surgery suits him better than that of A who has no evening hour. Should B acting as a locum-tenens under any conditions consent to continue attending A's patients? If he does, should he pay A any recompense such as half fees for a year? This is what A did himself 15 years ago in respect of the only case he ever took over in his capacity as locum. In that case the patient refused to go back to the principal, whose diagnosis and treatment he regarded as wrong. There is no suggestion of dissatisfaction in the present case. If B refuses attendance the patient would contentedly remain with A. The situation thus described is not uncommon and should not present any great difficulty, especially as it is for reasons of practical convenience, and not on any professional grounds that the patients are retaining permanently the services of the locum. Apart from the very special case where there is suggestion of sharp practice, the rule cannot be laid down that under *no* circumstances can the locum remain in attendance; the situation should be avoided as far as possible, but an inflexible rule would either be ignored or would result in the loss of the patient by both practitioners. Where the situation cannot be avoided we feel—and this feeling has been recognised in practice—that a certain proportion of the fees received from the transferees are due for a period to the original practitioner. No precise arrangement has been sanctioned, as far as we know, by any ethical body, but we have heard of one association of doctors which insures itself against unpleasantnesses under this head. Of the five or six members forming the group, one undertakes the whole secretarial work of the practices, his dispenser keeping the books and accounts. When a member goes on holiday one of his colleagues, the next on the rota, does the extra work, receiving two-thirds of the receipts, the holiday-maker one-third. This is done on a simple card system; the extra worker takes out cards for each patient of the absentee, records his doings thereon, and sends them in to the secretary to be priced. They are checked, altered if necessary, and paid in by the returned holiday-maker, who collects his third in the usual way. If a member falls ill his work is done by a member of the group who in this case takes one-third, the invalid two-thirds. Should a patient forsake his doctor for another member of the group that member pays two years' purchase for him, the amount being calculated on the amount brought in on an average of three previous years. The successful running of such a scheme implies mutual trust, and it is evidently desirable for the group to include all who have considerable practices in the locality.

IODINE AND GOITRE.

IN a recent report to his education authority Dr. W. M. Ash describes an experiment, arranged by his predecessor, to test the effect of administering iodine widely in a goitrous county. In a selected area of Derbyshire the public water-supply was iodised and iodised sweets were supplied weekly to the children of certain schools, beginning in January, 1925. In the first school, where both water and sweets were taken, the percentage of goitrous girls was 24·5 on Feb. 26th, and had gone up to 66·9 on Dec. 10th. In the second (an infants') school, no iodised sweets were taken, only the iodised water; on Feb. 27th the goitrous percentage was for girls 29·6, for boys 18·6; on Dec. 11th, 42·3 for girls and 26·0 for boys. In the third school, where the girls, aged 7–14, received sweets during the first half of the year and iodised water during the second half, the goitrous percentage in February, 1925, was 46·8, and in January, 1926, was 51·5. An experienced practitioner, Dr. Philip Turton, made all the examinations of the children. The experiment was on a small scale and is to be continued during 1926, but Dr. Ash has advised the discontinuance of the iodisation of the water-supply. In a similar experiment at Rochester, U.S.A., which Dr. Ash quotes, the water-supply was iodised twice a year for about two or three weeks, and the yearly dose of sodium iodide was estimated at about 7·5 mg., as compared with 14·9 mg. in the Derbyshire experiment. At Rochester it was claimed that the goitrous children were reduced in number from 3844 in 1923 to 1766 in 1924, but the figure for 1925 shows an increase to 2010. In a closely reasoned statement Dr. Ash discusses the iodine deficiency theory of goitre, remarking that goitre is or has been found near the sea, where there is presumably plenty

of iodine in the air—e.g., the Maritime Alps, the shores of the Mediterranean, the plains of the river Po, the Isle of Arran, the delta of the Ganges, the Isle of Wight, Cumberland, Somerset, and the seaboard of the South Island of New Zealand. He rejects the assumption that every enlarged thyroid is a diseased condition, and agrees with R. McCarrison that thyroid enlargement in children is frequently physiological and disappears spontaneously. Stress and strain, he thinks, may have something to do with the enlargements, while a nutritional factor may also be at work. Dr. Ash founds his opinions partly on personal observation and partly on the replies to a questionnaire circulated by him to doctors practising in Derbyshire. The conclusions reached by him from the study of these replies are as follows: (1) In practically all districts there has been a diminution in prevalence. (2) The proportion of females to males affected varies from 3 to 1 to 10 to 1. (3) Where the water-supply has not been improved the prevalence of goitre has remained stationary. (4) There seems to be a connexion between the presence of goitre and hard waters containing sedimentary pollution. Goitre is more prevalent in the limestone districts of the county than on the millstone grit. (5) The type of goitre in the past was the huge cystic and adenomatous goitre. The present type is smaller and softer. Dr. Ash quotes Sir James Berry as an authority who regards the iodine deficiency theory as unproven, and holds that iodine treatment for goitre should be carried out with discrimination and not by wholesale medication. Sir Alexander Houston, who has discussed the question of adding iodine to water-supplies in his last three reports to the Metropolitan Water Board, also advocates caution. In America Dr. C. L. Hartsock, of Cleveland, has been led to doubt the advisability of the general use of iodised salt by observing a large number of cases of hyperthyroidism among middle-aged men and women who have been taking iodine.[1] Apparently iodine is sold largely for its anti-goitrous action in pharmacies and grocery stores of the Middle West. On the other hand, in the August number of the *American Journal of American Sciences* Dr. K. A. Martin claims to have obtained great benefit from the administration of iodine in cases of simple goitre associated with symptoms which he ascribes to iodine deficiency, and the success achieved by the iodisation of the salt-supply in certain Swiss cantons seems to be generally admitted. The proportion of children aged 12-15 with thyroid enlargement in the Cincinnati schools is high—38 per cent. in boys and 59 in girls—and a recent U.S. Public Health Report[2] gives data for the belief that these children are definitely inferior in certain physical measurements. It might seem, on the face of it, a curious proceeding to give the whole of a community iodine because a certain number of its members suffer from goitre or to give a whole family iodised salt in order that one member may benefit, but it is reasonable to normalise the intake of iodine in a community where there is reasonable suspicion that many members are suffering from its deficiency.

SERUM TREATMENT OF GONORRHŒA.

IT is generally recognised that when some complication arises in the course of an ordinary attack of gonorrhœa the acute discharge almost immediately undergoes a change. There is a reduction or total disappearance of the discharge and in many cases this reduction is permanent; when the complication resolves the gonorrhœal infection is found to be at an end. In such cases it might be well to regard the complication as a metastasis. Even when the urethral discharge reappears in these cases the bacterial picture is altered; in films the gonococci are rare and mostly extracellular, and many other organisms are present in the film, as is common in old chronic infections. The cause of this change is not understood, but Dr. E. Sterian, of Bucharest, in a recent address to the Vienna Congress of the German Urological Society, has interpreted it as an immunising process which he explains as follows. The immunisation is due not to the gonococcus alone, but to a mixture of organisms. Likewise, each attack of gonorrhœa is due to an invasion, not by the gonococcus, but by a mixture of organisms; the aerobic gonococcus is allied—apparently necessarily allied—with facultative aerobes, with facultative anaerobes, and with strict anaerobes. According to Dr. Sterian, the disease resolves itself into three phases. First the gonococcus invades the polymorphonuclear cells, kills them, and frees the protoplasm by disruption of the cell. Secondly, the facultative aerobes—e.g., staphylococci and streptococci—seize this protoplasm and by their ferments split it into peptones and polypeptides. Thirdly, the facultative anaerobes, such as *B. coli*, seize the peptones and polypeptides and split these still further into such products as indol, which are responsible for the fœtid smell of the discharge. If this is accepted it will be seen that the grouping of microbes is not fortuitous, but determined by the chemical changes of protein necessary for the life of members of the alliance. Acting on this assumption, Sterian had produced a polymicrobic serum; this he obtained by injecting the discharge into the tunica vaginalis of a horse and thence later to the peritoneal cavity. Serum taken from horses thus treated has been injected into patients suffering from severe gonorrhœa, and Dr. Sterian states that he has had considerable success, especially in removing severe complicated infections. Several controversial principles are, however, involved in his claims. It is by no means universally agreed that gonorrhœa is an infection by a mixture of organisms, at any rate at the outset. Dr. Sterian also makes a large assumption when he regards improvement following on the occurrence of a metastasis as due to specific immunity. Many factors may be involved; fever, for instance, may play a part. The results of treatment with serum, which have not, so far, been uniformly favourable, are also possibly due to other factors. In this department of medicine protein shock therapy has occasionally had successful results, especially in gonorrhœal arthritis. The gonococcus produces an endotoxin, and so far as is known, no exotoxin; medical experience of such organisms suggests that they are unlikely to yield readily to serum therapy. The production of a serum by the use of a polymicrobic antigen is novel in its conception and must involve new methods to secure standardisation and estimation of potency; these are not disclosed by Dr. Sterian.

THE WORK OF THE MILBANK TRUST.

AMERICAN public health administration is distinguished by the intensive manner in which in one area or another special reforms have been pushed forward with a fervour which is scarcely known on this side of the Atlantic. New York City, under the leadership of the late Dr. Hermann Biggs, was a pioneer in utilising the bacteriological laboratory as an aid in administration. In many American cities and counties at the present time energetic campaigns are progressing to secure a population immune against diphtheria. In some rural areas, especially in the south, concentrated attention has been devoted to immunisation of the population against enteric infection; though evidently as sanitation and sanitary administration become developed, such immunisation will be rendered unnecessary. But the work of the Milbank Memorial Fund[1] stands out by itself among American demonstrations, in its wideness of scope and broad sweep of policy. This Fund was founded a few years ago with a large capital, which is being administered by a board of directors and advisory council numbering among its members some

[1] Jour. Amer. Med. Assoc., May 1st, 1926.
[2] Vol. xli., No. 36, Washington, 1926.

[1] The annual report for the year 1925 may be obtained from the offices of the Fund, 49, Wall-street, New York.

very distinguished names in science and medicine, and a large part of its income is now being devoted to three special demonstrations, one in a section of New York City, one in the City of Syracuse, and one in the county of Cattarangus in New York State. The two last named have been sufficiently long at work to show the importance of the experiment and the prospect of successful results. What the Milbank Trust does in undertaking a demonstration is to approach the local public health authority of the district concerned with an offer of financial help to provide additional workers, to pay present officials on a full-time basis at an adequate rate, to pay for active public health propaganda, and in various other ways to make local health administration as complete and as satisfactory as is possible in view of local conditions. In each area the financial assistance of the Fund is regarded as supplementary to, and as not in the slightest degree supplanting the efforts of, the local governing body or of existent local voluntary agencies. The responsibility and the authority of the local authority remain supreme; and the method adopted by the trustees of the Fund is one which is designed to secure continued local support and to enable the local authority to continue the same high standard of work at the end of the series of years during which it is intended to continue the coöperative experiment. Thus it is anticipated that by means of the demonstration several objects will be attained:—

1. A fairly rapid rise in the local standard of public health administration.
2. By local experimentation there will be a "testing out" of methods of administration which will secure the maximum effect for a given expenditure of time, effort, and money.
3. The benefits of efficient and complete sanitary work will be demonstrated to the local authorities concerned, and other cities and counties will be stimulated to more rapid progress than is at present being realised.

Each demonstration operates in a setting of local official agencies; it does not supersede, but serves to strengthen these. But while this programme is sound in principle, it is evident that measurement of progress made—whether by vital statistics or by details of administrative work accomplished—must be difficult. In the two areas in which most work has been done there is evidence of improving sickness and death-rates; and a detailed examination of activities in the special departments of work shows improved machinery, greatly extended work, increasing collaboration with private medical practitioners, and a degree of public interest in the details of the work which is encouraging. In this country it is doubtful whether these methods would achieve similar results, but the further course of the experiments will be watched with interest.

POTTERS' ROT.

THE pottery industry has long possessed an unenviable reputation for subjecting its employees to two definite occupational risks—lead poisoning and phthisis. The former, although it has by no means disappeared, has lost many of its terrors since its method of causation, by dust inhalation, was recognised, since compensation was awarded to its victims, and means for its prevention were adopted. More persons are employed in the industry to-day than in 1900, but there are now less than 50 cases of plumbism annually, and those cases are not so severe as the 210 cases of 1900 and the 113 cases of 1901. Much less has been heard about phthisis in the industry, known locally as "potters' rot," just as the same condition in the Sheffield cutlery trade is known as "grinders' rot." The disease is now known to result among potters from inhaling dust of flint, which is pure silica. Flint dust occurs in many pottery processes from the time the flints are ground in mills to the use of the powder in mixing the earthenware for the saggars in which the articles are placed during burning. After long periods of occupational life, generally ten years and over, inhalation of fine silica dust results in the formation of fibrosis, or silicosis, in the lungs. This condition may in itself incapacitate or even kill its possessor; but far more frequently the victim falls a prey to tuberculous infection, which in such a case runs a rapid and usually fatal course. The Workmen's Compensation (Silicosis) Acts, 1918 and 1924, permit compensation to be awarded for silicosis in those industries to which those Acts have been applied; but so far only the Refractories Industries have been brought within the scope of the Acts.

The question, however, of applying the Acts to the pottery industry is now under consideration, and a report has just been issued[1] by the Home Office of a medical investigation undertaken to acquire information as to the prevalence of silicosis in this industry. The investigators had had previous experience as members of the Medical Board under the Refractories Industries Scheme; they examined 344 males and 224 females, finding silicosis in 76 males and 11 females. Radiography was employed to assist the clinical inquiry in nearly half the cases. One point of interest emerging is that pulmonary fibrosis was diagnosed by medical examination at an earlier period than that at which silicosis was visible in the X ray picture. This is in contrast with the finding of the Miners' Phthisis Bureau of South Africa, where radiography is claimed to give the most certain indications, but it should be remembered that pottery dust, which may contain flint, ball clay and china clay, may give a different pathological picture. The men and women examined were actually at work; hence tuberculous infection, which rapidly incapacitates for work, was not a feature of the cases seen and no sputum examinations were made. Evidence of tuberculous infection in cases of silicosis must rather be sought among mortality statistics than among operatives at work. No information is given in the report of the average composition and amount of dust present at the different processes, but the varying amount of silicosis found appears to bear a close relation to the known exposure to silica dust. The disease was not to be discovered among those exposed to dust of plaster-of-Paris in modelling and mould-making, or of red marl used for Rockingham ware. On account of their longer periods of occupational life, more males than females were found with silicosis; where the dust was of unmixed flint, 32 per cent. of the men examined were affected; where the dust was composite, 24·7 per cent.; but in other groups the disease was far less prevalent. The broad result indicates that silicosis is liable to occur in many branches of the industry, and exists to-day to a considerable extent. Reference is made in the report to the widespread prevalence of bronchitis among potters, but how far this disease is an independent condition or one coincident with silicosis is not indicated. Modellers, mould-makers and red marl workers, whose work need not bring them into contact with silica dust, could be excluded when a scheme of compensation is being drawn. Dr. E. L. Middleton, in a preface to the report, indicates some of the ways in which the risk can be greatly minimised. But some scheme is required to do immediate justice to the victims of silicosis, and, indirectly, to concentrate attention on means of prevention.

THE Tuberculosis Week-End organised by the two tuberculosis societies opens at 5 P.M. next Friday at the Royal Society of Medicine with a paper by Dr. Strandberg, of the Finsen Institute.

THE next session of the General Medical Council will commence at 2 P.M. on Tuesday, Nov. 23rd, when Sir Donald MacAlister, the President, will take the chair and give an address. The Council will continue to sit from day to day until the termination of their business.

[1] Report on the Incidence of Silicosis in the Pottery Industry. C. L. Sutherland and S. Bryson, London: H. M. Stationery Office. 1926. Pp. 52. 1s. 6d.

Modern Technique in Treatment.

A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions.

CXCVII.

TREATMENT OF DISTENSION OVERFLOW OF URINE.

BY the phrases "distension overflow" or "false incontinence" is meant that condition in which the urinary bladder is full and voluntary micturition is impossible, but dribbling of small quantities of urine occurs involuntarily at frequent intervals. The condition is brought about by interference, either mechanical or nervous, with the mechanism of micturition. It occurs most commonly in cases of enlargement of the prostate gland, other common causes in men being urethral stricture and tabes dorsalis. In women it is sometimes due to the retroverted gravid uterus or other pelvic tumours obstructing the outflow of urine by pressure on, and longitudinal stretching of, the urethra. In children a pin-hole meatus or a tight phimosis may be responsible. For the sake of precision, distension overflow following enlargement of the prostate will here be described.

Symptoms of Distension.

The symptoms complained of include thirst, headache, drowsiness, nausea, and the constant wetting of the clothes. There is complete inability to control the escape of urine but usually no pain. The patient is usually 50 or older, appears haggard and looks ill, the ammoniacal smell of decomposing urine is obvious. The tongue is dry and brown, and the mouth foul. The skin feels dry and inelastic. The heart is enlarged and hypertrophied, and the aortic second sound may be accentuated. The abdomen is distended, and the outline of an inverted pear-shaped swelling may be seen and felt rising out of the pelvis. This swelling is "tense-elastic" on palpation, and pressure on it may produce a desire to micturate, but often results only in forcing some urine out of the bladder. The tumour is dull to percussion, while the flanks of the patient are resonant. The swelling may extend above the umbilicus, and even within an inch of the xiphisternum. Per rectum the prostate may be pushed back by the vesical distension, but the gland is usually greatly increased in height so that the bladder base is reached by the examining finger with difficulty, if at all. The median groove on the dorsum of the prostate is obliterated, and the whole gland may project back into the lumen of the rectum. The patient feels ill, is nauseated and constipated, and worried by the constant dribbling of urine, but the urgency of his condition is much less apparent to him than to his medical attendant. The impulse immediately to pass a catheter and relieve the distension of the bladder must be resisted, especially when the patient presents himself in the consulting-room. The risks of the immediate complete relief by catheterisation of a patient suffering from distension overflow are so great that such treatment is always dangerous and may well prove fatal. The sudden removal of the pressure of urine in the renal pelves against which the kidneys have been secreting appears so to upset the equilibrium that instead of continuing to secrete urine only the kidneys allow blood to permeate them, and the urine soon becomes porter-coloured and thick with mucus; or complete anuria may ensue. To avoid this risk the patient ought to be sent to bed immediately, a specimen of blood taken and its urea-content determined. This acts as a guide to his progress under treatment. It is best *not* to pass a catheter at this stage; the incontinence can be disregarded for the moment, every effort being concentrated on combating the uræmia that threatens the patient's life.

Measures to combat uræmia include:—

1. Unrestricted fluids by the mouth, such as water, barley-water, lemonade, weak tea.
2. Saline purges, so that one or two free evacuations are secured daily.
3. Diuretics such as caffeine, theocin, and theobromine may each be tried in turn until it is discovered which increases the urinary output most; the selected drug should then be pushed to secure its optimum action.
4. Excretion through the skin is encouraged by hot packs, hot-air baths, and the injection of pilocarpine. The patient is kept wrapped in blankets, and is well supplied with hot-water bottles.
5. The diet, when the patient can be induced to eat anything, must consist entirely of milk and glucose.

The progress of the patient may be gauged by the improvement in his clinical condition, and by the steady lessening of the urea-content of his blood. When the improvement ceases, then, and not till then, is it time to consider how the distension of the bladder may be relieved.

Methods of Evacuation of the Bladder.

The following technique of evacuation has given the best results in my hands.

1. Pass a large silk-web catheter—e.g., 20 F.—with the most rigid aseptic precautions and the utmost gentleness. The use of the large size catheter and the exercise of great patience in passing it will usually overcome any difficulty in entering the bladder. In the event of failure with the ordinary instrument, the "coudé" or "bi-coudé" catheters may be tried, and if they fail, a silver prostatic catheter of similar size will surely succeed. This last weapon, however, is a dangerous one, and should be used only by an experienced operator.
2. When the catheter has been passed it should be tied in, the escape of urine being first controlled by plugging the exit with a spigot.
3. The height of the fundus of the bladder is now marked with a skin pencil on the abdominal wall, and six ounces of urine allowed *slowly* to escape. The spigot is then reinserted firmly, and the height of the bladder again marked.
4. Four hours later another six ounces of urine are allowed to escape *slowly*, and the height of the bladder marked. If this height is greater than that at the end of removal of the first six ounces, then more urine should be let out slowly till the bladder sinks to a level slightly lower than that indicated by the second mark on the skin. The new level of the fundus is then marked.
5. At the end of every period of four hours the procedure described above is carried out. This gradual emptying of the bladder may occupy several days, the organ gradually recedes into the pelvis, and finally empties.

If during the tedious emptying process the catheter becomes foul, or pus begins to exude between it and the wall of the urethra, then the catheter must be carefully changed. If by accident the spigot comes out, and urine escapes suddenly, the nurse must be instructed immediately to fill the bladder with boric lotion up to its former level. If symptoms of uræmia such as drowsiness, headache, or thirst reappear, or if the tongue become dry, or the urea-content of the blood increase, then the rate of withdrawal of the urine must be slowed and the general measures against uræmia pushed with renewed energy. If any blood appear in the urine withdrawn the rate of emptying must be checked immediately.

It will be seen that this method of evacuation aims at relieving the abnormal "back pressure" by such easy stages that the already damaged kidney function is as little interfered with as possible.

When the bladder is empty the catheter is removed, and the patient may be able to pass water again naturally. The subsequent treatment depends on the state of the patient's general health. Usually operation to remove the cause of obstruction is not advisable till one or two months later, but if the patient seems very well it may be undertaken within a fortnight. Most of these patients will be unable to pass urine satisfactorily pending operation for prostatectomy. They will therefore be better off and safer from another attack of retention if they are provided with a suprapubic drain.

The Avoidance of Trauma and Infection.

Before deciding to adopt the procedure described above I have tried many methods to avoid trauma incidental to the tying in of a large catheter for long periods, and the infection that occurs so frequently

in spite of the most elaborate precautions. Among these methods were: (1) drainage of the bladder with ureteric catheters passed into it either directly when possible or through a catheterising cystoscope; (2) suprapubic drainage with a self-retaining catheter inserted by open operation, and tied into the bladder wall with a purse-string suture; (3) tapping of the bladder suprapubically under a local anæsthetic through a small one inch incision in the skin with a trocar and cannula sufficiently large to permit the passage through it of a large self-retaining catheter. These were abandoned because in (1) the small lumen of the ureteric catheter was liable to become blocked, while the shock, inseparable even from small operations such as were involved in (2) and (3), appeared to prejudice the patient's chances of recovery. I have not tried the device of connecting a catheter tied in the bladder to a reservoir of boric lotion maintained at such height that the outflow of urine is very gradual. Theoretically this ought to be the most successful of all in the treatment of this condition. Its objects are those of the method recommended above, the only difference being that the evacuation of the bladder may be carried out even more gradually by this means than by the procedure I am accustomed to use. The disadvantage of the hydrostatic method is that it requires more apparatus and is rather more difficult to watch than the simple method which I have found successful.

W. E. M. MITCHELL, *M.C.*, M.B., B.S. Lond., F.R.C.S., Eng.,
Late Chief Assistant to Surgical Unit, St. Bartholomew's Hospital, and Clinical Assistant, St. Peter's Hospital.

Special Articles.

SOUTH AFRICAN INSTITUTE FOR MEDICAL RESEARCH.

ANNUAL REPORT.

THE continuous ill-health which led to the resignation of Dr. W. Watkins-Pitchford, the former director of this Institute, prevented him from preparing the annual report for 1925. It has now been issued[1] by Sir Spencer Lister, who on August 1st assumed the post of director, and whose recently augmented staff is as follows:—

Research Division.—Bacteriologist and Pathologist: Dr. J. H. Harvey Pirie. Fellow in Industrial Hygiene: Dr. A. Mavrogordato. Parasitologist: Dr. Annie Porter. Honorary Protozoologist: Prof. H. B. Fantham. Entomologist: Dr. A. Ingram. Biochemist: Dr. F. William Fox.

Routine Division.—Superintendent: Dr. G. Buchanan. Senior Pathologists: Dr. J. G. Becker, Dr. A. Sutherland Strachan, and Dr. F. W. Simson. Assistant Pathologists: Dr. D. Ordman, Dr. L. W. Barlow, and Dr. W. K. Dunscombe.

Sir Spencer Lister reports that the total cost of maintenance of the Institute as a whole, for the financial year ended on March 31st, 1926, was £35,768, an increase of over £6000 on the cost for the preceding year being due to the establishment of new departments in the research division. The cost of maintenance of this division for the year accounted for £16,451, whilst that of the routine division accounted for £19,317. The cost of the research division was met by contributions in equal proportions from the Union Government and the Witwatersrand Native Labour Association. In the routine division the expenditure was fully met by the revenue earned from the sale of vaccines and sera, and from the performance of routine pathological and other examinations for the Government, hospitals, municipalities, the mining industry, and the medical profession.

[1] Published by the South African Institute for Medical Research. P.O. Box 1038. Johannesburg. 1926.

Considerable expansion has taken place during the year in the research division, to which departments of medical entomology and biochemistry have been added, whilst the department of bacteriology has been expanded by the addition of a branch dealing with plague research. In connexion with this latter, field investigations have been carried out at a camp maintained in the Orange Free State Province. A survey of the mosquito and molluscan carriers of malaria and bilharzia, respectively, has also been initiated and a field officer appointed for this purpose. This work will probably be extended at an early date. A new arrangement has been entered into with the University of the Witwatersrand under which the Institute has become responsible, through its officers, for the staffing and development of the department of pathology and bacteriology of the medical school. The additional laboratories and other buildings, the erection of which was commenced two years ago, have now been completed and have been brought into commission. New roadways are also being made, and the whole of the grounds enclosed within a boundary wall and railing, these improvements having been made possible by a grant of £5000 for this purpose from the Witwatersrand Native Labour Association.

Activities of the Research Division.

Plague.—Some ten species of veld rodents have been tested for their susceptibility to plague, and all have been found to be more sensitive to infection than the guinea-pig or the black rat. The species of practical importance in the spread of plague on the high veld are the Lobengula gerbille, the multimammate mouse, and the ground-squirrel, and in lower, more bushy country, the striped-mouse. Lobengula gerbilles have been found to be very cannibalistic in their habits, readily eating any sick or weakly member of their community. Plague is readily transmitted amongst them by eating infected comrades, and evidence has been adduced suggesting that plague may be actively spread amongst them by feeding as well as by fleas. It is not thought likely, however, that spread by feeding is a method of any importance in other species of veld rodents.

Cuti-vaccination, which has been found satisfactory in the prevention of anthrax, was found to be of no protective value against plague. Sensitised vaccines were not found to be of any greater value than ordinary killed vaccines either in prophylaxis or treatment, and mercurochrome was found valueless.

What is believed to be a new disease, caused by a hitherto undescribed Gram-positive motile bacillus, has been found in gerbilles; the essential pathological lesions are extensive necroses in the liver and spleen with bacteræmia. It is proposed to try on a large field scale whether or not the disease can be turned to practical use for the extermination of gerbilles.

The entomological work done during the year has been concerned entirely with the investigation of plague, and has been mainly confined to the collection and examination of the ectoparasites of the small carnivora and rodents of the veld.

Industrial Hygiene.—An attempt has been made to correlate underground conditions with the incidence of silicosis by studying the historical aspect of the disease as met with on the Witwatersrand. Methods for the further improvement of underground conditions with respect to dust prevention, and for the closer control of tuberculosis, have been investigated. Additional studies have been undertaken concerning the part played by bacterial infections of the lungs as an important factor in the production of silicosis. A consideration of the evidence available suggests that tuberculosis is now the dominating factor in the disabling and fatal form of miners' phthisis now met with on the Witwatersrand, and that it is quite as important to study environmental conditions from the point of view of tuberculosis as it is from the point of view of air-borne phthisis-producing dust. It appears probable, on the strength of experimental and

autopsy findings, that dust inhaled can facilitate secondary infections, tuberculous and otherwise, before it has produced a recognisable clinical silicosis. From the point of view of underground conditions estimations of air-borne dust afford a valuable measure when dust concentration is comparatively heavy, but are not so useful when dust concentration is comparatively light. A steady fall over a period of years in dust concentration is not associated with a corresponding fall in silicosis incidence. An explanation suggested is, that after air-borne dust has fallen to a concentration at which it will not produce disabling lung lesions per se, it still facilitates chronic respiratory infection, particularly when much water is used for dust-laying.

Schistosomiasis and other fluke infestations have been investigated. A total of 1827 snails was examined for flukes during the year. Some experimental work with fluke larvæ obtained from *Limnæa truncatula* established that this snail, which is the common host of liver fluke of sheep in Europe, was also a host of *Fasciola hepatica* in South Africa.

Parasites of Plague Rodents.—A beginning has been made on a survey of the animal endoparasites found in rodents that carry plague, and some interesting results have already accrued, including the finding of a fluke in the intestine of the gerbille, *Tatera lobengulæ*.

Routine Division.

The total number of investigations carried out in the routine division of the Institute during the year ending Dec. 31st, 1925, was 52,844. This is an increase on the figure for 1924 of 11,011. Examinations for *B. pestis* in humans totalled only 78 in 1925, as against 193 in 1924. The relative number of positive results is also less this year (21·8 per cent., as against 33·7 per cent. in 1924).

Post-mortem examinations made on behalf of the Johannesburg General Hospital numbered 342, as compared with 428 in 1924.

The routine tests done in the biochemical department continue to increase steadily, the growing appreciation of the value of blood analysis being specially notable.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

The Patent Medicine Nuisance.

THE very large output of German chemical factories, although gratifying from the national point of view, is in some respects less beneficial to the medical profession. Compounds are invented in such numbers that it is almost impossible for the average practitioner to follow their progress. The profession is drowned in advertisements of new products, and there is hardly one day all the year round when the doctor does not receive by post an advertisement of some new compound, with information concerning its effects. Sometimes this information is supplied by medical men of good standing—even by hospital physicians and their assistants; sometimes it is written by people who are little known to the profession. Often samples are sent with the circulars, and quite often agents of the various factories call at the consulting-room of the medical man to draw his attention to the new remedy. These agents are sometimes younger medical men who for financial reasons have not yet been able to settle down; sometimes widows or children of deceased practitioners are employed in the work, so that it is difficult not to receive them. Most of the new compounds—whether in the form of tabloids for oral use or as ampullæ for subcutaneous injection—soon disappear to make room for newer compounds advertised in the same way. Some, however, become familiar to the profession, and medical men are now accustomed to prescribe tabloids and ampullæ produced in bulk by the chemical factories, instead of having their prescriptions dispensed according to the requirements of individual patients. The apothecaries, in consequence, are losing their dispensing skill, as their work is chiefly the sale of ready-made compounds. This state of affairs is causing chemists to ask what is the good of their learning and studying pharmacy for several years if at the end of it all they are to become mere dealers in the products of chemical works. A proposal has been made to convene a committee of medical men, hospital physicians, pharmacologists, and apothecaries, so that measures may be devised to remedy the nuisance.

The Virus of Scarlet Fever.

Prof. Ulrich Friedemann, physician-in-chief to the department of infectious diseases at the Virchow Hospital, recently read a paper before the Berlin Medical Society on the transmission of scarlet fever. According to researches of the Dicks, a streptococcus termed *S. hæmolyticus scarlatinæ* is the causal organism of the disease. Prof. Friedemann, who has had a large number of scarlet fever patients in his department, is now able to give the results of his own investigations into the subject. He found that when a culture of streptococci was inoculated into the tonsils of an assistant (a willing coöperator in the experiment) typical scarlet fever developed, and the patient's serum gave excellent results in the treatment of scarlet fever in others. The disease, he states, is transmitted by droplet infection from secretions of the mouth. The old idea that scales from the skin of convalescents are responsible for infection is a mistaken one. Prof. Friedemann examined the scales of 50 patients, and only in one did he find streptococci in the desquamation; all the rest were sterile. He ascertained, however, that the streptococcus is not only present in the tonsils and in the mouth, but also in purulent secretions such as pus from a complicating otitis media. The streptococcus was further found on the walls of sick-rooms, on the beds, curtains, and utensils used by the patients, and in great quantity also in the air of the rooms. These results led him to recommend as absolutely necessary thorough disinfection of sick-rooms at the end of the illness. On the tonsils streptococci were often present six weeks after the attack was over, although they did not cause any symptoms. The time of isolation should, therefore, be longer than the usual six weeks, for children sent home thus prematurely may easily infect healthy members of their families. Before being dismissed from a hospital, convalescents should be kept for some time in a separate room where they are safe from streptococci in the air.

Death of Prof. Heubner.

The death is announced of Prof. Otto Heubner, who formerly occupied the chair of pædiatrics at Berlin University. His principal service to medicine was that he invented new methods of feeding infants, and gave warning against the too lengthy sterilisation of milk. He was also one of the first to recognise the great value of Behring's discovery of the use of serum in diphtheria, which he could administer on a large scale in his department in Leipzic. A standard work on the diseases of children was published by him in 1903. Prof. Heubner was born in 1843 in Vogtland, Saxony, and throughout his life showed himself a Saxon in speech and temperament. In 1894 he succeeded Prof. Henoch in Berlin, and became the first ordinary professor of pædiatrics at a Prussian university. Up to this time there were no chairs in this or any other special branch of medicine, but Prof. Heubner's struggle for the acknowledgment of pædiatrics has so far succeeded that now nearly every German university appoints an ordinary professor to teach the subject. Prof. Heubner remained at work in Berlin until 1913, then retiring to live in Dresden, where he has now died at the age of 83. His son is the well-known professor of pharmacology at the University of Göttingen, Prof. Wolfgang Heubner.

Medical Women.

According to recent statistics the number of qualified medical women in Germany is 327, of whom

152 are married. It is interesting to know that 68 of them are married to medical men; 25 of the 31 medical women in Munich and 8 of the 15 in Frankfort have doctors as husbands. The unmarried belong for the greater part to the younger generation who have recently settled in practice. Medical women, as a rule, prefer residence in large cities to smaller towns or the country. In Berlin 5·6 per cent. of the profession belong to the female sex; in the medium towns the percentage is much smaller, and in the country there are scarcely any medical women engaged in practice.

The Berlin municipal authorities have decided that patients in the municipal hospitals who supply blood for purposes of transfusion shall receive an allowance of M.10–30 (10*s.* to £1 10*s.*) according to the quantity of blood taken. In this way the difficulty of getting volunteers may be avoided.

The Trustees of the Rockefeller Foundation have declared their willingness to give 250,000 dollars to the Munich Institute for Psychical Research, for the erection of a new building, on condition that 15,000 dollars are provided from other sources for its maintenance and working. The city authorities of Munich have given already an area in one of the suburbs to the institute without demanding payment. Prof. Kräpelin, until his recent death, was the institute's director.

The city of Nürnberg and several other cities have decided that henceforth no advertisements of breweries shall be allowed in public places, in municipal buildings, and in tramcars. They point out that by these advertisements alcoholism is promoted, and that the city has to spend much more money for the care of drunkards than it gains from the advertisements.

IRELAND.

(FROM OUR OWN CORRESPONDENT.)

The Rotunda Hospital.

THE tenure of office of Dr. Gibbon FitzGibbon as Master of the Rotunda Hospital having come to an end, Dr. Bethel Solomons has been elected to succeed him. Dr. Solomons was assistant Master of the Rotunda Hospital during part of the Masterships of Dr. E. Hastings Tweedy and Dr. Henry Jellett, and for the past 12 years has been gynæcologist to Mercer's Hospital. He has written a "Handbook of Gynæcology," now in its second edition, and has edited Dr. Tweedy's "Practical Midwifery." He has been President of the Section of Obstetrics of the Royal Academy of Medicine in Ireland, President of the Dublin University Biological Association, and is at present Vice-President of the Royal College of Physicians of Ireland. In his younger days he was an International Rugby player, and he keeps up an interest in athletic sport. His energy and personality cannot fail to make his influence as Master of the Rotunda powerful in the obstetric world.

University College Medical Society.

At the opening meeting of the University College Medical Society, held last week, Dr. E. T. Freeman, the President, read a thoughtful paper on Medicine from Three Angles. He discussed the changes that had taken place in the practice of medicine and in the relation of the public to medicine in the past 15 years. There had been a gradual diminution in the incidence of the infectious diseases and of the great killing diseases, and medicine nowadays was mainly concerned with investigating slight departures from health. The greater complexity of investigation required a large extension of hospital treatment, so that the hospitals, originally intended as refuges for the poor, were now largely used by the poorer middle-class, a class able to bear a share of the cost. Dr. J. F. O'Carroll, in proposing a vote of thanks, discussed the real value of an increased expectation of life, and urged young medical men to pursue their profession in a spirit of perfect honesty toward themselves and their fellow men. The vote was seconded by Mr. T. Hennessy, who criticised the attitude of the public and of the legislature toward questions of health. The new county hospitals were, for the most part, indistinguishable from the old workhouses, and were as backward as they were 30 or 40 years ago. Medical inspection of school-children was only carried out in two towns in the Free State. The State was unwilling to pay adequate salaries for scientific services. It was recently proposed to appoint a whole-time bacteriologist to the Ministry of Agriculture, and the person appointed, who should be a Bachelor of Science or hold an equal qualification, was to receive the salary of £100 a year. Dr. R. J. Rowlette and Dr. W. D. O'Kelly also spoke.

Sir Robert Jones in Dublin.

Sir Robert Jones paid a flying visit to Dublin last week in order to address the meeting of the National Children's Hospital. He urged the transfer of such institutions to the country, and spoke of the necessity of giving fresh air and sunlight to sick children. In the evening he was entertained at a special dinner given in his honour by the Rotary Club. Nearly 200 guests were present. In an address Sir Robert Jones said that he estimated that there were 12,000 or 14,000 cripples in the Irish Free State. Twenty-five per cent. of cases of deformity were due to rickets, and about 50 per cent. to tuberculous disease. The medical profession now knew enough, if it was given the opportunity, to eradicate these two diseases in a small number of years. About 50 per cent. of the cases of tuberculosis of the bones was due to milk and 30 per cent. to direct contact with the human consumptive. In England it had been found that one out of ten specimens of milk examined contained living tubercle bacilli. Sir Robert Jones thought that the work done in the Dublin hospitals which he had visited that day was splendid; but the conditions in which the surgeons in them worked were really almost pathetic. The surgeons and physicians were struggling to make the best of a bad machine. They were trying to imitate the sun by bringing in ultra-violet ray lamps. His feeling was that the best thing for them to consider with regard to these children's hospitals was to get them out into the country.

WIRELESS IN HOSPITALS.—The *Daily News* scheme for equipping the London hospitals with wireless has now been completed. Since the fund was instituted in May last year 122 hospitals have been equipped, and 13,456 head-phones and 479 loud speakers provided at a cost of a little more than £25,000.

THE LATE DR. W. R. POLLARD.—By the death of Dr. William Robert Pollard, at the age of 82, Blackburn has lost its oldest medical practitioner. He was a native of the town and was educated at the local grammar school, and after studying medicine in Dublin, qualified as L.R.C.S.I. in 1873, and M.R.C.P. Edin. in 1882. Returning to Blackburn, he started work there on his own account. Besides carrying on a large general practice he was medical officer to the Blackburn Union Infirmary from 1888 to 1912, by which time the calls on his services had grown so greatly that he had to give up this post. At the time also he was medical officer to the Church and Oswaldtwistle District Council, and honorary medical officer to the Blackburn Ragged School and the Blackburn Orphanage. His death left one ambition unfulfilled: he had wished to complete half a century's service as medical officer to the Blackburn Rural District Council—in another year he would have done so, for his appointment dated from 1877. The council and community greatly valued his services. On his retirement from the Blackburn Union Infirmary the staff presented him with a handsome gift of plate. He was very popular in the town and took a great interest in its affairs. Dr. Pollard leaves a widow, three married daughters, and two sons in the medical profession, one of whom is in practice in Blackburn and the other in Halifax.

Public Health Services.

RECORD CARDS AS AN INDEX OF EFFICIENCY.

A PSEUDONYMOUS correspondent to the *Times* recently described the examination of the record cards kept by insurance practitioners as a "medical inquisition." He thinks that "insurance doctors may be unjustly fined" as the result of an estimation of the number of entries on a sample of cards taken haphazard. The method he describes is what is known as a dipping audit which enables the Ministry of Health to classify practitioners as to whether they are or are not keeping records. We understand that where there is reason to doubt that the practitioner is neglecting this part of his contract a further stringent examination is made of at least 25 per cent. of his cards and in the estimation of the value of the records various tests are applied, such as the character of the clinical notes, the number of attendances given in certain cases of acute illness, and the average number of attendances and visits given to his patients generally. Disciplinary action is not likely to be taken until a very full investigation has been made. It can hardly be denied that the record cards constitute some index of a practitioner's efficiency.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

THE following are some of the 1925 statistics of two county boroughs, two large urban districts, and two cities :—

Name of district.	Estimated mid-year population (R.-G.).	Birth-rate.	Death-rates per 1000 of the population.					Death-rates per 1000 births.	
			All causes.	Tuberculosis.	Cancer.	Resp. diseases with influenza.	Heart disease.	Infant mortality.	Maternal mort. from childbirth.
Croydon C.B. .	199,300	17·1	10·9	0·92	1·60	1·8	1·3	55	3·8
Hastings C.B..	60,470	13·0	14·5	1·39	2·11	2·6	2·3	40	2·6
Willesden U.D. . .	172,503	16·0	9·8	0·86	1·40	1·9	1·3	62	2·2
Tottenham U.D. . .	153,600	18·0	10·4	0·90	1·39	1·9	1·9	54	2·2
York C.	84,630	18·9	12·4	1·26	1·41	2·0	1·8	86	1·8
Carlisle C. ..	55,160	18·8	13·5	1·02	1·34	2·2	1·7	78	2·9

Croydon.

Dr. H. P. Newsholme describes an outbreak of food-borne paratyphoid B fever, which caused the illness of about 80 persons in Croydon and district. The first case was notified on Sept. 5th, and as the patient had been for a fortnight's holiday to the seaside it was at first assumed that she had contracted the infection elsewhere. She was the head assistant of a confectioner's shop, and inquiries showed that nine out of a total staff of 15 had had similar attacks beginning between August 31st and Sept. 2nd. None of the Croydon cases ended fatally, although some had severe complications, including sharp hæmorrhage from the bowels. Exhaustive inquiries were made into the exact source of infection, and ultimately the outbreak was traced definitely to veal and ham pies and fancy cakes infected at a late stage of their preparation by a pastrycook, who had suffered from an unrecognised attack of the illness. The origin of the pastrycook's illness could not be traced, but it was within the bakery, either from infected materials or an infecting person, and it may have accounted for some earlier cases occurring in the district during July and August. No case was traced to the pastry of this firm subsequent to the withdrawal of the infecting pastrycook from work. Some of the lessons from the outbreak are : The need for better washing arrangements on such premises ; the need for scrupulous care in the cleansing of utensils ; and the need for means whereby every process involving personal handling is followed by heating of the food-stuff sufficient to prevent infection. This particular firm used bacterial virus for the extermination of rats and mice, and although it was possible to exclude this as a cause of the present outbreak, Dr. Newsholme emphasises the necessity of protecting food from this source of contamination. He further suggests that the trade might with advantage consider the adoption of some form of industrial insurance for the maintenance of employees who are obliged to leave work because they are carriers of infectious disease. The main conclusions arising out of the epidemic have been referred to the Bakery and Confectionery Section of the London Chamber of Commerce, the National Association of Master Bakers and the Croydon Master Bakers Association.

The only case of diphtheria among the staff of the hospital was that of a ward maid who had not been Schick-tested and immunised as is the custom for newly engaged members of the staff. Arrangements have been made with the Croydon General Hospital for the use of their light clinic. Thirty-eight cases of malnutrition, rickets, and other diseases were under treatment during the year, and the results were encouraging. Coöperation with the same hospital has led to the establishment of an orthopædic scheme, which includes clinics for massage, remedial exercises and electric treatment, and in-patient treatment, when necessary, at the St. Nicholas and St. Martin Orthopædic Hospital, Surrey. During 1925 there were 3406 births, and 609 expectant mothers attended the antenatal clinic. A course of six lectures to midwives was delivered by Dr. J. A. Willett, of the City of London Maternity Hospital. Of the eight cases of puerperal sepsis notified six proved fatal. There were 22 cases of ophthalmia neonatorum, in three of which vision was impaired.

In spite of increasing activity in private and public enterprise, there is much leeway to be made up in housing. Over 5 per cent. of 3492 working-class houses inspected were found to be overcrowded. The standard adopted was that of the local by-laws for houses let in lodgings—viz., 360 cubic feet in bedrooms for each person over ten and 400 cubic feet where a room is used both as living and sleeping room, with 250 cubic feet for persons under ten. The municipal lodging-house has 101 cubicles for lodgers. The charge per night is 9*d.* and the nightly average of lodgers was 99. The receipts for the year were £1346 and the expenditure £1485. Of 94 samples of milk examined for tubercle one was found to be infected, and as a result one aged cow was found in a borough cowshed with a tuberculous udder. It was subsequently slaughtered and compensation at one quarter of the value (£7) was paid under the new Act. Of 99 samples of ordinary milk examined for bacteria, 87 conformed to the Grade A standard, but a large proportion had been subjected to commercial pasteurisation.

A five years' survey of the school work shows great progress. Thus the percentage of verminous children, 13·2 in 1921, has come steadily down to 8·0 in 1925, and the children treated for dental trouble numbered 1210 in 1921 and 3357 in 1925. The work will be greatly facilitated by the opening of "admirable clinic premises" in 1926. Dr. Newsholme points out that it is difficult to gauge the changes in physical fitness resulting from school medical work owing to differences in standard due to changes in the medical staff. He is able, however, for two schools, to give a comparison of average heights and weights in 1905 (when Dr. Meredith Richards was school medical officer

and in 1925. The comparison shows a clear general increase both in height and weight among boys and girls at all age-periods in these schools.

Hastings.

Dr. G. R. Bruce reports that the most important recent event has been the opening of the new venereal disease clinic in January, 1924. This building has been designed on model lines, is entirely adequate for its purpose, and has been visited by many officers of other authorities. The water-supply is insufficient for the increasing needs of the community and the Council is looking to the chalk area in the Cradle valley to the east of Eastbourne to provide a satisfactory supply sufficient for many generations. Dr. Bruce points out that many elderly or retired persons and invalids come to live in Hastings and help to swell the death-rate from cancer and circulatory and respiratory diseases. When the correction factor (0·718) is used the death-rate of 14·5 becomes 10·4. Antenatal work is as yet only carried out on a small scale. There were 783 births, and 72 expectant mothers attended the two antenatal clinics. The municipal cases admitted to Fern Bank maternity home numbered 35, attendance at one of the antenatal clinics being a condition of admission. An orthopædic scheme in connexion with the Royal East Sussex Hospital was under consideration during the year.

Willesden.

Dr. George F. Buchan reports that there were 37 notifications of ophthalmia neonatorum—a case rate of 13·4 per 1000 births. Private doctors attended in 16 cases, midwives in 17, whilst the remaining four were born in hospital. In one patient one eye was permanently injured and two cases were under treatment at the end of the year. Proceedings were taken against a doctor and a midwife for failure to notify. The case against the doctor was dismissed, but the midwife was fined £20 and subsequently struck off the roll. At two of the three schools for mothers the work is hampered by the unsuitability of the premises, but a large number of health talks and demonstrations were given throughout the year. No general orthopædic scheme has yet been adopted, but instruments are provided in necessitous cases and crippled children are sent to outside institutions. The school premises for the physically defective at Furness-road are unsatisfactory as there is no playground available for open-air classes for the crippled children. The classes for stammering children are being extended. The medical staff of the department are taking part in the inquiries into defective vision and anthropometry instituted by the Board of Education. Dr. Buchan complains of the cumbersome procedure, in the existing state of the law, which is necessary in order to secure a reasonable standard of repair of dwelling-houses.

Many interesting matters are dealt with in appendices to the report. Appendix H. deals with mentally defective children and dull and backward children. Dr. Buchan draws attention to the fact that the definition of the mentally defective child in the Education Act of 1921 differs from that given in the Mental Deficiency Act of 1913. He thinks that "mental defect" in the Education Act may mean an educational disability only and that there is, therefore, no power to send a child to a special school unless it can be certified under the Mental Deficiency Act of 1913. Correspondence with the Board of Education is given, which shows that the Board differs from this view, but as yet there has been no decision on the matter by the courts. The question arose owing to the refusal of a parent to allow his child to be sent to the Leinster-road mentally defectives' school. Dr. Buchan also points out that 40 per cent. of the children at this school are educationally retarded and that 60 per cent. are mentally defective within the meaning of the Mental Deficiency Act. The 40 per cent. could be transferred to classes for dull and backward children if such were available, and it is suggested that such classes should serve groups of schools and should be established at suitable centres throughout Willesden. In another appendix it is shown that the Pound Lane site, on which there is a proposal to establish an open-air school, is not large enough to provide for the needs of Willesden. The proposed site of two acres would be large enough to accommodate the 100 children at present attending the physically defective schools, but it is shown that there are about 600 children in Willesden who need this provision.

Another appendix deals with the school dental scheme of October, 1924, under which a fee of 2*s.* 6*d.* was to be charged to the parents for the re-treatment of routine cases. A table is given which shows that during a year's operation there were 13,482 routine inspections, and the number of children found to require treatment was 9431. Of these only 898 received treatment at the clinics; about 100 were treated elsewhere. Dental treatment at the Willesden schools is chiefly given to the most neglected and difficult type of case, and is largely of a palliative nature instead of being preventive and constructive in accordance with the principles laid down by the Ministry of Health. A revised scheme was adopted by the Education Committee in February, 1926. Dr. Buchan points out that an addition of one dentist to the staff should be made during 1927 and other increases in succeeding years as required. An appendix by Dr. H. Haldin-Davis, dermatologist to the council, deals with light treatment, which was established in November, 1925. Some improvement was noted even in the six and a half weeks before the end of the year and striking results were obtained in severe cases of asthma and alopecia areata. The type of lamp used is a flaming carbon arc of Siebe and Gorman working at 30 amperes. Dr. Bessie R. Mackenzie gives a history of health visiting in Willesden. During 1902, the year preceding the appointment of the first health visitor, the infant mortality-rate was 130. There are now 20 health visitors and the infant mortality-rates for the last four years were: 59, 53, 73, and 62. During the last six years the number of infants breast-fed for nine months has gone up from 15 per cent. to 19 per cent., while the number solely bottle-fed from birth has gone down from 6 per cent. to 4 per cent. In a further appendix Dr. W. D. Champneys reviews the present position of work against cancer, and expresses the opinion that by far the most important measure for securing the early diagnosis and treatment of cancer—and one that has not been so far tried in this country—is the cancer clinic for free diagnosis. Such a clinic, he considers, should be established by the council.

Tottenham.

Dr. David C. Kirkhope says that many houses contain two or more families, and occasionally a family in a single room, notwithstanding that they are both able and willing to pay for more commodious dwellings. There are 2800 families upon the register of those who seek houses upon the council's estate. Tottenham has no land available unless the houses are of the large tenement type, which system Dr. Kirkhope does not recommend. Adequate means of transit from Tottenham to the metropolis are not available. The solution of the housing difficulty appears to lie in the extension and enlargement of the underground system. The pollution of the River Lea below Tottenham lock has received the consideration of the council on several occasions, and it is now hoped that the authorities concerned with the river will take action. Dr. Kirkhope goes on to complain of the nuisance caused by the tipping of refuse, both by his own and neighbouring authorities.

There were 17 notifications of encephalitis lethargica with eight deaths. The home treatment of scarlet fever is encouraged in Tottenham and the use of scarlet fever antitoxin for the inoculation of susceptible contacts has been tried with partial success. The

immunity conferred by the intramuscular injection of 5 c.cm. of concentrated serum only seems to last for about a fortnight. In two cases mothers who declined inoculation contracted the disease, and rendered the attempt at immunisation useless. A better result was obtained in the case of a school in which there were recurring cases of scarlet fever which ceased after the immunisation of half of the scholars with the consent of their parents. Grade A (tuberculin tested) milk is now supplied to mothers and children through the centres and to the creche. There were 338 new cases at the antenatal clinic, the total births numbering 2756. The scheme for dealing with school-children who need operative treatment for tonsils and adenoids has given entire satisfaction. A contract has been made with the North Middlesex Hospital. The tonsils are enucleated under an anæsthetic in the forenoon. Later in the day the children are taken home in an ambulance in the custody of a nurse. If there is any apprehension of after trouble they are retained in hospital for a longer period. Good results are also being obtained by ionisation at the clinic for otorrhœa, which was started two years ago and is under the charge of Dr. A. R. Friel. There is still a large percentage of refusals by parents of dental treatment for the children.

York.

Dr. P. R. McNaught reports that the corporation during the last five years have built 367 houses at their Tang Hall estate, and that 312 houses were in course of erection at the end of 1925. Nevertheless, there are 1400 applicants on the waiting-list for houses and developments in the confectionery trade and the erection of a sugar-beet factory just outside the city will increase the demand. Many distressing cases of overcrowding are cited. An antenatal clinic is conducted by the Infants' Welfare Association and was attended by 113 women during the year. There were also 129 attendances at the antenatal clinic of the maternity hospital, at which 271 mothers were confined during the year. The neonatal mortality was high (43) and just half the total infant mortality. Forty-six samples of milk were submitted to bacterial examination and 19 were reported to be dirty and unfit for consumption. Six of the 19 were samples of the milk produced at the municipal sanatorium. Two of the 36 samples contained tubercle bacilli.

Carlisle.

Dr. Joseph Beard reports that three out of 26 samples of milk were found to contain tubercle bacilli. As a result four milch cows were eliminated from the herds. It is difficult to estimate the real shortage of houses. Dr. Beard puts it at 1000. An inspection of the Currock estate of the corporation during the year showed that 50 out of 222 tenants were subletting. Seven of the houses were found to be seriously overcrowded and a number of others were dirty. The shortage of houses has been aggravated by the falling off of building by private enterprise since 1907 and the demolition of many tenements in carrying out reconstruction schemes. The only institutional provision for tuberculosis is 20 beds at Blencathra Sanatorium. These are intended for early cases, but advanced cases are also admitted for short courses of instructional treatment, and some cases of surgical tuberculosis are transferred to Blencathra from the Cumberland Infirmary. There were 166 new cases at the antenatal clinic, the total births in the city being 1045; the neonatal mortality-rate was 37, nearly half that for infant mortality. The city council have employed a veterinary surgeon to inspect cows for the last 27 years, whose practice it is to examine all the new cows in the city within three days of their purchase. During 1925, 146 cows were so examined and 14 were returned to the would-be vendors for various reasons. The city is exceptional in having a satisfactory public abattoir.

SCHOOL MEDICAL SERVICE.

Name of district.	No. on roll.	Av. elem. school attendance.	No. of routine children examined.	No. of special examinations and re-inspections.	Percentage of children found on routine examination requiring treatment.*
Edmonton ..	10,447	9,605	3,294	15,292	31·0
Cambridge ..	7,232	6,260	2,246	2,358	5·7
Colchester ..	—†	5,863	1,818	3,129	24·0

* Excluding uncleanliness and dental defects.
† Not given.

Edmonton.

In Edmonton there is close coördination between the child welfare work and the school medical service, for the dental clinic serves both infants and school-children as does the orthopædic clinic for massage and muscle re-education, and Dr. H. W. Harding, the school medical officer, is on the committee for the local crèche. There is, however, no definite link with the Juvenile Employment Committee nor with the factory surgeon, and the local work of the guardians, the County Council, the Home Office, and the general hospitals is unrelated to that of the local education authority. The large variation from previous years in the numbers of defects found during 1925 is accounted for by the different standards adopted by the new medical inspector, Dr. Marjorie Dalby; thus, there were 280 cases of functional heart conditions and anæmia noted as against 39 for 1924, and enlarged tonsils were noted in 610 cases compared with 173 in 1924. There is no open-air school. Dinners to the number of 52,466 were given to school-children during the year and 1375 16 oz. bottles of cod-liver oil were provided in addition to milk meals, but it is doubtful if the end results of wholesale extra dieting compare favourably with the benefits and educational value of an open-air régime. No organiser of physical training is employed. Special classes are held for the partially blind and the partially deaf while mental defectives are educated at a special school in Enfield, but Dr. Harding believes the atmosphere of the elementary school is preferable for cripples.

Cambridge.

The apparent smallness in the incidence of defects in Cambridge is largely accounted for by the fact that all dental conditions are excluded from Dr. A. L. Laird's report to be dealt with separately by Mr. W. B. Grandison, the public dental officer. Statistical tables presented by Dr. Laird and figures supplied by Dr. A. Mabel Gurney show evidence of improved physique in both boys and girls and the percentage of children in whom no defect was found was higher in 1925 than ever before, while the proportion of children found to be clean was the highest yet recorded. There has been a marked and steady decrease in otorrhœa from 3·7 per cent. in 1911 to 0·7 per cent. in 1925, and in deafness from 5·6 per cent. in 1911 to 1·9 per cent. in 1925. Dr. Laird regrets that although the plans for the new open-air school have been approved, a site purchased, and bricks deposited ready for use, no further action is being taken for reasons of economy. Meanwhile, the temporary open-air school established in 1916 continues to do excellent work, which is further extended by the helpful activities of the Invalid Children's Aid Association which sent 46 children to the seaside during 1925. An orthopædic scheme is now working in conjunction with Addenbrooke's Hospital, which also carries out much of the general treatment required by the local authority. Much useful information is given by Mr. Grandison, whose boast it is that "there are 5000 school-children in Cambridge who now show no evidence of dental caries . . . . due principally to active dental treatment."

Colchester.

Dr. W. F. Corfield surveys the changes that have taken place in the school medical service during the past five years. Cleanliness has markedly improved as have also the conditions of clothing and boots. Malnutrition, anæmia, rickets, and spinal curvatures all show lessened incidence, but enlarged tonsils and adenoids were more prevalent in 1925. This increase, perhaps, may be more apparent than real, since special attention was focused on the results of operation in a special inquiry by Dr. R. W. Cushing. At the same time, Colchester is not alone in reporting bigger incidence of morbid throat conditions during this year. Blepharitis and conjunctivitis are less frequent owing to increased cleanliness and relief of eye-strain by glasses, but the numbers of scalp ringworm cases still keep high, though the increased facilities for X ray treatment at the Essex County Hospital should materially reduce them. Routine medical inspections were attended by 77 per cent. of parents. Special classes are held for stammerers and for cases of spinal curvature, and under the orthopædic scheme Mr. W. Howell, of Brookfield Orthopædic Hospital, Walthamstow, visits the clinic periodically. Special classes are also open for mentally defective children and for the partially blind, while open-air classes are held during the summer at most of the elementary schools.

INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED OCT. 30TH, 1926.

Notifications.—The following cases of infectious disease were notified during the week :—Small-pox, 131 (last week 126) ; scarlet fever, 1924 ; diphtheria, 1157 ; enteric fever, 48 ; pneumonia, 828 ; puerperal fever, 45 ; puerperal pyrexia, 114 ; cerebro-spinal fever, 10 ; acute poliomyelitis, 78 ; acute polio-encephalitis, 9 ; encephalitis lethargica, 33 ; continued fever, 1 ; dysentery, 4 ; ophthalmia neonatorum, 114. There were no cases of cholera, plague, or typhus fever notified during the week. No cases of small-pox were notified from London or the southern counties. The cases of poliomyelitis and polio-encephalitis taken together are less numerous than last week, the counties reporting more than 3 being London 15 (Deptford 2, Islington 4, Kensington 1, Lewisham 1, Paddington 1, Marylebone 1, Southwark 1, Wandsworth 4); Kent 5 (Broadstairs 4, Faversham 1); Leicester 8 (Leicester C.B. 2, the remainder scattered over five urban and rural districts) ; Warwick 5 (Birmingham 1, Leamington 2, rural districts 2).

Deaths.—In the aggregate of great towns including London, there was no death from small-pox, 1 (0) from enteric fever, 7 (1) from measles, 3 (0) from scarlet fever, 14 (4) from whooping-cough, 43 (8) from diphtheria, 124 (30) from diarrhœa and enteritis under 2 years, and 71 (15) from influenza. The figures in parentheses are those for London itself.

The Services.

ROYAL ARMY MEDICAL CORPS.

Maj. A. G. Biggam is secd. for serv. under the Foreign Office.

Maj. J. J. Magner is restd. to the estabt.

Capts. A. Jackson and J. W. C. Stubbs to be Majs.

The undermentioned Capts to be Majs. : G. D. Jameson, J. G. Ronaldson, W. D. Arthur, K. P. MacKenzie, R. R. G. Atkins, R. H. Leigh, J. H. G. Hunter, W. G. Shakespeare, O. C. Link, E. E. Holden, R. G. Martyn, R. H. Hodges, and H. W. Browne.

Capts. Sarat Chandra Basu and Pearey Lall Whig relinquish their temp. commns.

The King has approved the retirement of Col. J. H. McDonald and Lt.-Col. D. McCay.

TERRITORIAL ARMY.

Maj. C. D. Mathias, having attained the age limit, is retd. and retains his rank, with permission to wear the prescribed uniform.

Capts. E. L. Sandiland and H. T. Bates to be Majs.

Maj. George Young, late R.A.M.C., T.F., to be Capt., and relinquishes the rank of Maj.

Lt. H. V. Forster to be Capt.

J. W. Eames to be Lt.

The King has conferred the Territorial Decoration upon Majs. W. C. Gunn, R. Henry, and F. E. H. Keogh.

ROYAL AIR FORCE.

Temp. Lt. V. G. Pedley, General List (Army), Dental Surgeon, is granted a temporary commission as a Flying Officer on attachment to the R.A.F.

Flying Officer G. J. Hanly is promoted to the rank of Flight Lt.

DEATHS IN THE SERVICES.

Major Charles Louis Williams, I.M.S. (retd.), who died suddenly at Banstead, Surrey, on Oct. 31st, was a Liverpool man, and studied at Liverpool and the University of Edinburgh, where he graduated M.B., C.M. in 1886 and M.D. in 1889. He also took the diploma of M.R.C.S. Eng. in 1888, and the D.P.H. Camb. in 1896. He was Holt Scholar at University College, Liverpool, and lecturer in the Liverpool Tropical School, and served for a period as house surgeon in the Royal Infirmary, Liverpool, sometime afterwards becoming medical superintendent to the Booth Shipping Line. Entering the Indian Medical Service, he served for 17 years in India and became surgeon to the General Hospital, Madras. On the outbreak of the late war he was appointed to the Hospital for Indian Troops at the Pavilion, Brighton, and after the departure of the Indians held several important surgical posts, eventually acting as a surgeon specialist. After service in connexion with the Ministry of Pensions, Major Williams retired two years ago. He leaves a widow and three daughters.

MEDICINE AND THE LAW.

Contamination of Meat by Flies: Butcher's Successful Appeal.

A PARAGRAPH in the *Times* records a successful appeal to the Middlesex Sessions by an Acton butcher, who had been fined £2 and ordered to pay £5 5s. costs on a conviction for neglecting to guard meat against contamination by flies. The brief report states that at the hearing of the appeal butchers gave evidence that glass fronts to shop windows encouraged flies, and that open windows were better, as a through current of air kept the flies on the wing. Then follows the information that the Court found that the defendant did not take all the precautions he should have done, but that his neglect was not wilful, whereupon the Chairman (Sir Montagu Sharpe, K.C.) said that on this finding the appeal would be allowed, but without costs. This somewhat puzzling result is possibly due to a compromise between the members of the Bench. If a valid enactment requires a butcher to take certain precautions, and if he is either actually or constructively aware of his obligation and fails to discharge it, the wilfulness or innocence of his motives would seem to be immaterial, unless the by-law or other enactment is so expressed as to give a defendant the benefit of good intentions.

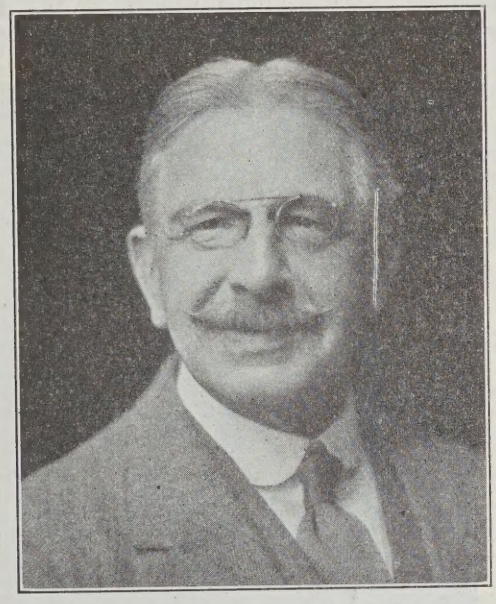
Wilfulness as an element in the commission of an offence presents well-known difficulties. Baron Bramwell, on a prosecution under a Local Act of 1774, governing the maintenance of the Aire and Calder navigation system, once held that " wilfully " throwing soil into a river meant wantonly or causelessly, and did not apply to a person acting in the course of his business and in the supposed assertion of a legal right. On the other hand, a surveyor was once held to have committed the offence of " wilfully obstructing " the highway by leaving large stones on a road under repair inadequately lighted at night. The stones were placed there purposely ; it was culpable negligence not to warn the public of the danger; therefore the obstruction was wilful. In the case of the Acton butcher, the decision of the Court perhaps means that, though he did not protect his meat as he ought to have done, he honestly thought his own method of non-protection was the best method of preventing contamination by flies. If this is to be a good defence, it is a waste of time to undertake further prosecutions of this kind. Much depends, of course, upon the exact wording of the requirement which the butcher was charged with having failed to satisfy ; but in the sphere of public health it is the facts, not the motives, which matter.

Obituary.

FRANCIS MITCHELL CAIRD, LL.D., M.B., F.R.C.S. EDIN.

Prof. Caird, of Edinburgh, who died on Nov. 1st, at the age of 73, was one of the early practitioners of antiseptic surgery. His powers as a teacher were valued highly by the University which he served, whilst the skill and knowledge he acquired brought him an international reputation.

Francis Mitchell Caird was educated at the Royal High School and at the University of Edinburgh. During his time as a student he acted as clinical dresser to Lord Lister, then Regius Professor of Clinical Surgery in the University, and learned directly from



PROF. F. M. CAIRD.

him the theory and methods which were changing surgical practice at that time. After graduating in 1877 Caird decided to take up surgery, and with this in view went on to the University of Strassburg, where he studied under Recklinghausen and Joessel, and laid the foundation of that detailed anatomical and pathological knowledge on which his work was always based. On his return to Edinburgh he continued his surgical studies, at the same time acting as demonstrator in Minto House and the Surgeons' Hall under Dr. Cossar Ewart, and became F.R.C.S. in 1880. After three years of anatomical work he was selected by Prof. Chiene as his assistant both in private work and in the teaching of large classes at the infirmary. In 1886 he was appointed assistant surgeon to the Royal Infirmary, and was made lecturer on surgery by the University and the Royal College of Surgeons of Edinburgh. During the next twenty years, in which the extra-mural school was at the height of its fame, Caird lectured regularly and with success. In 1900 he was appointed Surgeon to the Royal Infirmary in full charge of wards, and eight years later succeeded to the Regius Chair of Clinical Surgery. This he occupied until his retirement, but during the late war, although more than 60 years of age, he saw active service as consulting surgeon to the Expeditionary Force in France, where he took temporary rank as colonel.

Appreciation of Prof. Caird's services to surgery was frequently shown by academic honours. In 1901 he received the Victoria Liston Jubilee prize from the Royal College of Surgeons of Edinburgh for the greatest benefit done to practical surgery by any Fellow or Licentiate during the previous four years, and in 1912 he was elected President of the College. Of many Edinburgh societies, also, he was at one time or another president, including the Harveian Society and the Medico-Chirurgical Society, to whose proceedings he frequently contributed. In 1906 he was invited to deliver the annual address on Surgery to the Canadian Medical Association at Halifax. On his retirement in 1919 the University of Edinburgh made him LL.D.

As a surgeon Caird was notable for sound technique and painstaking carefulness. He was among the first who dared to perform abdominal operations and, later, to excise the tongue under local anæsthesia and the rectum under spinal anæsthesia. His kindness to his patients was proverbial, and he never spared himself where their welfare was concerned. His ability as a teacher, as has been mentioned, was considerable, and he was exceptionally skilful at illustrating his subject on the blackboard by means of drawings. The same talent for exposition is shown in the "Surgical Handbook" which he wrote in collaboration with Mr. C. W. Cathcart and in his other books and contributions to Edinburgh journals. Always he tried to avoid the narrow outlook, and every year he went on tour to see the main surgical centres on the Continent. Thus he came into touch with many foreign surgeons, among them counting as a personal friend Prof. Bier, of Berlin.

Caird's personality was charming. In spite of success he was a modest man, and to those needing his help he gave himself unsparingly. Before operation he inspired his patients with confidence, and afterwards gave them unceasing care, often visiting his wards in the small hours when he thought that this would increase their comfort. He was particularly interested in flowers, and was at one time President of the Botanical Society; after his retirement his chief hobby was gardening. Drawing and painting came easily to him; he was fond of music, and an omnivorous reader. In the City and University where he worked he will long be remembered for his personal, as well as his scientific attainments.

Prof. Caird leaves a widow, two daughters, and three sons, two of whom are members of the medical profession.

JAMES ERNEST LANE, F.R.C.S. ENG.,

CONSULTING SURGEON TO ST. MARY'S HOSPITAL.

WE regret to announce the death of Mr. James Ernest Lane, which occurred on Nov. 4th at the Star and Garter Home at Richmond, where he passed the last stages of a protracted illness bravely borne, following a fractured thigh.

Ernest Lane, as he was always called, was born in 1857 at 1, Grosvenor-place, the son of James R. Lane, F.R.C.S., surgeon to St. Mary's Hospital and the Lock Hospital, and the great nephew of Samuel Armstrong Lane, head of the Grosvenor-place School of Anatomy (connected in the first instance with St. George's Hospital), and one of the founders of St. Mary's Hospital, whither the school was transferred in 1854. Ernest Lane was educated at Lancing and Magdalen College School, and entered St. Mary's Hospital as a student in 1875, qualifying as M.R.C.S. in 1880, in which year he became resident medical officer of the hospital. He obtained the F.R.C.S. diploma in 1882, and was appointed demonstrator of anatomy in the medical school, holding the post until 1888, when he became lecturer on anatomy, a position which he filled during his protracted service as assistant surgeon. He became full surgeon to the hospital in 1904 and lecturer on surgery at the hospital, and was appointed consulting surgeon in 1922.

This long and close association with St. Mary's Hospital had its parallel in his connexion with the Lock Hospital, where he received his first appointment in 1878, and where for many years he filled various posts on the staff; he did notable work as surgeon in charge of the female V.D. department,

experience here being recognised by his appointment as a member of the Royal Commission on Venereal Diseases in 1913. The following extract from the minutes of the board of management dated Dec. 17th, 1925, testifies to the respect in which Lane was held by the institution:—

"That this Board, having heard the letter addressed to the Chairman from Mr. Ernest Lane resigning his position as honorary senior surgeon owing to his prolonged illness, resulting from his serious accident in November, 1923, accept the resignation with deep regret. The association of Mr. Lane's family with the hospitals dates back to 1846; his father and great-uncle having held the position of honorary surgeon before him, while Mr. Lane commenced his connexion in 1878, ultimately rising as they did to the highest post on the staff. The Board, in grateful remembrance of these long family records, desire in particular to place on their minutes an expression of their deep appreciation of the great services Mr. Lane has rendered."

Lane's connexion with the Royal College of Surgeons of England was also a long and close one. He was an examiner in elementary anatomy to the College as far back as 1891, became examiner in anatomy to the Conjoint Board in 1904, and in 1898 examiner in the same subject for the diploma of F.R.C.S. From 1907 to 1917 he was a member of the Court of Examiners of the College, he was for ten years a member of the Dental Board, and being elected to the Council in 1913 served until 1921 in that office. He also at different times acted as an examiner in surgery for commissions in the Royal Naval and Indian Medical Services.

In 1914, on the declaration of war, he first took charge as Major in the R.A.M.C.T. of the American Military Hospital at Paignton, and later was appointed to the 3rd London General Hospital, with which unit he worked until the end. Although not a prolific writer, Lane was the author of some sound articles on many aspects of venereal disease, among which may be mentioned various contributions to the Index of Treatment, and papers in THE LANCET on the general treatment of syphilis, and on the introduction of salvarsan contributed to the Transactions of the Royal Society of Medicine and to THE LANCET. He was also the editor of the 9th edition of "Heath's Practical Anatomy," and as President of the Harveian Society delivered a sound literary oration.

Lane's death deprives St. Mary's Hospital of the last direct link with its founders, and of a great representative of its work and traditions. His many posts on the staff have been enumerated; his assiduity in discharging them was exemplary, for it is on record that he lectured at 9 A.M. for four days a week during the winter sessions of 17 years and never once was late. To generations of men at St. Mary's Lane's lectures were the introduction to their work, and in their sports his figure was an equally intimate one. As a student he had been a keen athlete, a member of the football team, a winner of many events in the hospital sports, and the winner of the United Hospitals hurdles. He was president of the Hospital Students' Club, and when he presided over the annual dinner of the old students in 1910 his popularity was exemplified by an enthusiastic reception. And Lane's colleagues on the staff held him in similar esteem. He commanded respect by his absolutely straight and well-balanced attitude in matters affecting the welfare and conduct of the institution, while he was unfailingly generous and unselfish in dealing with his juniors. Many of these have had much to thank him for in the readiness with which he allowed them full opportunities for work in the beds under his charge. He was a prominent Freemason, and was one of those chiefly instrumental in founding the Sancta Maria Lodge in connexion with the hospital; for nearly 25 years he was secretary, and to him, in greatest part, the outstanding success of the Lodge is due.

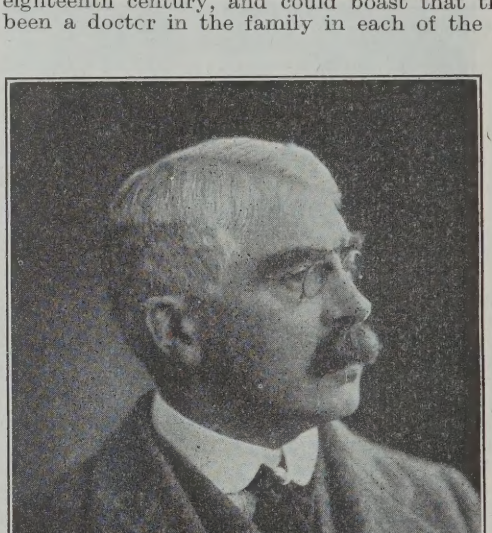
Not long after his retirement from active work at St. Mary's he sustained a serious accident, being knocked down by an omnibus in Regent-street. This left him bed-ridden, and for three years he endured his discomforts and disabilities with unfailing patience until he passed away peacefully at the Home for Disabled Officers, where he was cared for by one of his former pupils. The funeral took place at the Old Fulham Cemetery on Nov. 8th, and was attended by many of his former colleagues, his old pupils, and other personal friends.

In 1900 he married Miss Gertrude P. Woram, but leaves no family. Our deep sympathy is extended to his widow.

WILLIAM EDWARD FOTHERGILL, M.D., B.Sc. EDIN.

Prof. Fothergill has for many years been one of the most striking figures in Manchester medicine, and his sudden death at the Glasgow University dinner at Manchester on Nov. 4th will be greatly and widely regretted.

He was descended from a brother of Dr. John Fothergill, the eminent physician and botanist of the eighteenth century, and could boast that there has been a doctor in the family in each of the last six generations. He was properly proud of his Yorkshire descent, of the old family farm, Carr End, on Semmer Water off the Wensleydale Valley, and of the Quaker stock from which he arose. He was himself the son of Samuel and Emma Fothergill, of Darlington, County Durham, and was born in 1865. Entering the University of Edinburgh at the age of 17, he took degrees in Arts and Science before beginning the study of medicine. His undergraduate and early career was exceptionally brilliant in academic distinction; in practically all his examinations he obtained first-class honours; he won the Milner Fothergill Gold Medal in 1897, and he took many other prizes and medals. In 1895 he settled down to gynæcological practice in Manchester. It was not easy to make way at first among so many competitors, but success came without great delay. He secured honorary gynæcological appointments first at the Northern Hospital (1899), later at the Southern Hospital (1904), and, on the amalgamation with this, on the St. Mary's Hospitals of Manchester in 1905. In 1908 he was appointed assistant gynæcological surgeon to the Manchester Royal Infirmary, and in 1919, on the retirement of Prof. Archibald Donald, went on to the senior post. At the University in Manchester he became lecturer in 1901,



[*Lafayette.*

PROF. W. E. FOTHERGILL.

professor of obstetrics and gynæcology in 1920, and professor of clinical obstetrics and gynæcology in 1925. An interesting break in his purely gynæcological studies was afforded by his work as Director of the Clinical Laboratory at the Manchester Royal Infirmary from 1899 to 1905. The laboratory was then a new institution, and Fothergill was invited to take the post, as it was felt that his energy could make it a success where others might fail. Whilst holding this post he introduced radiological work to Manchester.

An enthusiastic teacher, with pithy, forceful sayings, he had strong views as to how gynæcology should be taught. Throughout all his teaching he pressed for a pathological or scientific classification of the subject as opposed to the haphazard description of diseases used in many text-books. This would save, he said, much space because it would remove the temptation to describe, as diseases, conditions which had no separate clinical existence; and something would be gained, also, by using a system with which students had become familiar from the beginning of their pathological work. These views he set out in the *Journal of Obstetrics and Gynæcology of the British Empire* of March, 1912, and all his books bear evidence of his orderly mind. He was a voluminous writer, and must have produced about a hundred papers in various journals, apart from larger works, which ran into many editions. While a successful operator in all fields of gynæcology, his especial interest lay in the development of the operation of colporrhaphy, which is associated with St. Mary's Hospitals (Manchester), and in which he took a leading part. Many surgeons from all parts of the world came to see his technique in this operation.

Fothergill was a good friend, an outspoken, fearless, critic of people and institutions. The severity of his criticism occasionally made him a difficult opponent of those who did not agree with his views. He was a brilliant raconteur, and was much sought after as a dinner speaker. His obituary notice of Lloyd Roberts in THE LANCET (1920, ii., 766) is a pleasing example of humour, portraiture, and good taste. He showed great interest in all the students did at the University, both at work and play, and was a regular attendant at the University Athletic Ground. Perhaps his happiest moments were when, after some University function or after a dinner, he collected a party of young students at his house, and round the fire told his tales and discussed the medical topics of the hour. On the day before he died he had cheerfully looked forward to continuing his hospital work for years to come.

Prof. Fothergill married in 1895 Edith, daughter of the late J. Dillon Woon, of Chelsea. She died some years ago.

MARY AELFREDA ST. CLAIR SWANN, M.B. LOND.

WE have already recorded the death, on Oct. 25th, of Dr. Mary Swann at the early age of 27. On leaving Cheltenham School in 1918 Miss Swann entered the medical school of the Royal Free Hospital. As a student she always appeared keenly interested in her work and anxious to make the most of her opportunities. At the same time she had many interests in the outside world, and knew an exceptionally large number of people. After graduating M.B. Lond. in 1924 she became a clinical assistant at the Royal Free Hospital and would have gone on to a house appointment but for a breakdown in health, which cut short her work over a year ago. A medical friend describes her as a physician of great promise whose loss "is mourned by a wide circle both of students and staff amongst whom she had many friends and was held in high esteem both for her intellectual and for her personal gifts. She was a physician who exercised the full force of her personality in her handling of patients and had the rare possession of a discriminating and tempered sympathy added to a sound basis of medical knowledge which augured well for her success. Had she been spared she would worthily and with distinction have upheld the traditions of her hospital."

Miss Swann was the sister of Dr. M. B. R. Swann, Fellow of Caius College, Cambridge, who died early this year.

FRANCIS WARNER, M.D., F.R.C.P. LOND., F.R.C.S. ENG.,

CONSULTING PHYSICIAN TO THE LONDON HOSPITAL.

Francis Warner, whose death has been recently chronicled, must be regretted by all, for he was a pioneer in branches of medicine with which his name will always be associated. He was the son of James Neatby Warner, and was born in 1847. As a boy he was educated at home, but at the age of 20 he won a junior scholarship at King's College, London, and embarked on a successful career as an undergraduate. Qualifying in 1870, he became house physician at King's College Hospital, and when, some four years later, after taking the M.D. Lond. and F.R.C.S. Eng., he was appointed to a children's hospital, his attention was soon turned towards that study of mental and nervous conditions which afterwards chiefly interested him. Noticing the frequency of headaches, insomnia, and defects in adaptation to school life, he began to build up a system of routine examination to serve as a guide to accurate prognosis and treatment. At that time medical literature did not give detailed descriptions of the signs of mental disease such as were available in the examination of pulmonary or cardiac conditions, and Dr. Warner set himself to supply the need for them. His investigations were made easier by appointment in 1876 as medical registrar to the London Hospital, and later as assistant physician to the East London Hospital for Children, to both of which institutions he eventually became physician. In 1883 his unusual knowledge was recognised by his election to the Fellowship of the Royal College of Physicians, a body which he later served as examiner, acting in the same capacity at several of the Universities.

The guiding principle of Dr. Warner's research was that the state and functions of the brain could be interpreted by the muscular movements to which they gave rise. In 1888 he read a paper before the Royal Society in which he discussed the significance of the spontaneous movements of infants at birth and up to the period of mental display, and showed their analogy to cell action in lower organisms. This was pioneer work in mental physiology, and Dr. Warner's hypothesis of a physical or neural response to mental action has been valuable in developing the diagnosis and treatment of mental disorders and deficiency. An immense amount of labour was devoted to the measurement and graphic record of expressive movements, and apparatus was devised for the analysis of their components. A Hunterian lecture to the Royal College of Surgeons in 1887 contains some account of his views on the action of nerve centres. His work, however, was practical as well as academic, and he was especially interested in the effects of environment on mental processes, and in the hereditary capabilities and limitations of children from the eugenic standpoint. Painstaking observations led him to enumerate 63 signs of defect in bodily development, and these he took as a basis for classifying children. In 1888, with the assistance of the British Medical Association and other bodies, he began a seven years' investigation into the physical and mental condition of 100,000 school-children in London. Dr. Warner examined these children individually, recording in each case any of the 63 signs which he had set himself to look for. A report on 50,000 of them was published in 1890 by the United States Government, and a full report was later published by the British Medical Association with recommendations on education and training, some of which, dealing with defective children, have since been carried out. From this time Dr. Warner was naturally recognised as an authority on the development and mental physiology of the child, and was frequently called upon to give evidence before

departmental committees and Royal Commissions, including the one which, in 1889, inquired into the condition of blind, deaf, and defective children and led to the School Board for London being empowered to provide special schools. His opinions were also frequently in request by the Local Government Board, the Home Office, and the Education Department. Numerous addresses and lectures, including the Milroy lectures of 1892, were delivered before medical, educational, and other bodies, and a number of books, including the "Study of Children" and the "Nervous System of the Child," added to his considerable influence on current teaching and his recognition as an able investigator.

In 1913 Dr. Warner resigned from the staff of the London Hospital and became consulting physician. In the following year, however, he gave a course of lectures at the hospital on neuroses and psychoses, and during the late war he generously offered his services to the hospital, and actually remained in residence there for three and a half years, working daily. In 1921 his national services were recognised by the grant of a pension on the Civil List.

Dr. Warner married in 1880 Louisa Loder, daughter of William Howard, of Hampstead. He leaves a daughter and a son, who is a member of the medical profession.

RICHARD NORRIS WOLFENDEN, M.D. CAMB., F.C.S., F.Z.S., F.L.S.

THE death is reported from his home at Grimsby, Ontario, of Dr. R. N. Wolfenden, to whom a debt is owed by laryngologists and zoologists alike. He was born at Bolton, Lancashire, in 1854, and after studying at Owens College and Christ's College, Cambridge, qualified in 1880 from the London Hospital, where he served on the house staff before becoming lecturer on physiology to Charing Cross Hospital Medical School, and obtaining an appointment at the Throat Hospital in Golden Square. At this time he did some work on the action of X rays on bacterial growth. His interest in laryngology was stimulated by association with Sir Morell Mackenzie, whom he accompanied to Berlin, and with whom he jointly founded the *Journal of Laryngology and Rhinology*. His own contributions included papers on neuroses of the throat and nasal passages, studies of laryngeal neoplasms, and of the control of respiration in singing. He took part in the German expedition to the Antarctic and the cruise of the *Silver Belle*, which led him to study the remarkable group of deep-sea crustacea known as copepods, on which he wrote a standard book. He joined the British Marine Biological Association, becoming a member of its governing body. His later work included studies of the plankton of the North Atlantic and of the nature and action of snake venom. Most of this work was done from Seaford, where he went to live after giving up appointments in London, which included that of consulting physician to the Pearl Assurance Company. A few years ago he retired to Canada.

THE LATE DR. R. H. LUCAS.—At the age of 81, Dr. Robert Harry Lucas has died at Bury St. Edmunds. He was the third son of Dr. Thomas Lucas, of Burwell, in Cambridgeshire, and qualified as M.R.C.S. Eng. in 1869. After a term as house surgeon at the Middlesex Hospital he was appointed resident medical officer and held this post until in 1879 he settled in Bury, where he soon developed a large practice. As surgeon to the West Suffolk Hospital for many years he had a large share in building up the surgical department of that institution, and it is recalled that in 1893 he was sent for to advise King Edward (then Prince of Wales), who was staying at Newmarket. Dr. Lucas retired from the hospital staff in 1909, being made consulting surgeon. He was attached for many years to the Loyal Suffolk Hussars (Yeomanry) as surgeon-captain, and during the late war worked at the Military Hospital of the Suffolk Regiment's Depôt. He was also a magistrate for the county. Until about six months ago he enjoyed good health. Dr. Lucas married in 1884 the daughter of Mr. Ambrose Smith, of Walford, who survives him with one son, Dr. H. A. Lucas, who is clinical pathologist to King's College Hospital.

Correspondence.

"Audi alteram partem."

EPIDEMIC ENCEPHALITIS IN DOGS.

To the Editor of THE LANCET.

SIR,—Mr. Pugh in his very valuable contribution in THE LANCET of Nov. 6th under the above title wishes to impale upon the horns of a dilemma the supporters of the conception of epidemic encephalitis as a specific and individual disease. In effect, he says that either the human and the canine diseases are identical—i.e., caused by the same virus—or else they are mere symptoms of some other infection—namely, influenza and distemper respectively.

In my view there is no such dilemma. There is another possibility—namely, predisposition of a sufferer from one infection to another. Many instances can be adduced; scarlet fever and diphtheria, malaria and dysentery, measles, whooping-cough, leprosy, possibly erythema nodosum, and tuberculosis. Influenza notoriously renders the sufferer susceptible to secondary invaders and, as Mr. Pugh states in his last paragraph, the *Bacillus bronchisepticus* is probably only a secondary invader in distemper.

On the other hand, there is the frequent occurrence of labial herpes in pneumonia and other respiratory infections. Believed to be a mere symptom, it is now recognised as a secondary infection due to a virus closely allied to that of encephalitis and capable of setting up encephalitis in the rabbit. Those who believe that influenza and human epidemic encephalitis are due to one and the same virus must produce epidemiological or bacteriological evidence in support of their view. My own experience, a field investigation of about 500 cases of epidemic encephalitis in Liverpool, is entirely against such a belief. It has shown:—

(*a*) That in seven years the outbreaks of influenza and encephalitis have never coincided; neither do they regularly alternate. The reference is to the dates of onset of encephalitis.

(*b*) That it is quite uncommon for a genuine attack of influenza, accompanied by symptoms affecting the lower respiratory tract, to precede the onset of encephalitis; where encephalitis has apparently followed an attack of supposed "influenza," this latter has in the majority of cases been admittedly the febrile onset of encephalitis.

(*c*) The entire absence of any case of epidemic encephalitis occurring in a family affected with an outbreak of influenza of the ordinary respiratory type.

(*d*) On the contrary, the occurrence of two or more cases of encephalitis of characteristic type in one family is a not infrequent event. I have seen three children affected quite typically—one developed characteristic sequelæ—the onset having been preceded by a relapse of the mother who had suffered a similar attack three years previously. Making allowance for the varied symptomatology of epidemic encephalitis it breeds true.

(*e*) On the other hand, during the climax of an influenzal wave, there is sometimes a small increase in the number of cases of epidemic encephalitis; this may be accounted for by influenza predisposing to encephalitis; the manner of this predisposition has been suggested by Yates [1]—namely, that morbid conditions of the nasal sinuses permit infection with the encephalitic virus.

There is one striking omission from Mr. Pugh's contribution. Did any cases of typical "bronchisepticus" character occur simultaneously and in close association with the cases of the epidemic which he describes? Or does he base his diagnosis of distemper on the accepted belief among veterinary practitioners that "the nervous aspect of distemper is merely one form of reaction among several to which the virus of distemper may give rise"? Has this belief received experimental verification? It would also be of interest to know whether there was evidence of case to case infection, and also the age incidence of the disease. The similarity of the symptoms of the canine epidemic at Sevenoaks to the human encephalitis is most marked. Whilst the viruses may be only allied and not identical this similarity does

[1] The Condition of the Accessory Sinuses in Encephalitis Lethargica, Proc. Roy. Soc. Med., xl., 10, 646 (October, 1925).

suggest the propriety of endeavouring to infect dogs with the human virus, if this has not been adequately tested.

I would add that I welcome Mr. Pugh's paper and consider that there is much to be gained from the joint discussion by veterinarians and medical men of allied problems in epidemiology.

I am, Sir, yours faithfully,

C. O. STALLYBRASS, M.D., D.P.H.

Liverpool, Nov. 6th, 1926.

PARAFFIN IN PLASTIC SURGERY OF THE NOSE.

To the Editor of THE LANCET.

SIR,—In your issue of March 27th you were good enough to review my book, "Plastic Surgery of the Nose," in terms very gratifying to an author pardonably interested in the reception of his first work. I trust you will not hold me in any way lacking in the appreciation due for this courtesy if I find myself in active disagreement with your reviewer concerning one of his expressions of individual opinion in which he traverses the position I took up in regard to the use of paraffin in naso-facial repair. My view is that the use of paraffin should be condemned. His view is that "the common small depression at the nasal bridge is best corrected by the injection of a small quantity of paraffin wax," and that "the result is quite permanent."

The question is: When may the result be pronounced "quite permanent"? Practically all cases demanding surgical interference to get rid of the injurious effects of injected paraffin had gone for several years before there was occasion to doubt the permanence of the repair, and most of them for several years more before the condition became so menacing that it was no longer possible to defer consultation for relief. That is the characteristic of injected paraffin; there may be "permanence" for ten years and then paraffinoma in the eleventh or twelfth.

The injuries produced are peculiar to the material. The tissues are intolerant of any foreign body inserted among them, and there is persistent effort directed towards its expulsion. With most of them the expulsion is early and violent. With paraffin it is slower, but not less certain. There is a tendency for the particles to disseminate even without pressure, this being due to the nature of the substance; but where, as in the case mentioned, the material is employed to give a support, pressure is inevitable, and the process of dissemination, with its sequence of infiltration and inflammation, is hastened. When it is known beyond peradventure that these things do happen, how can anyone possibly proceed upon the assumption that in a given instance they will not?

For those who believed, and those who still believe, in the efficacy of paraffin, the nose has always been a favourite field. That is why the majority of cases calling for relief are nose cases. Anyone who sees a few of them will want no more to do with paraffin for any correction. It may be encapsulated and tumescent, or it may travel into the tissues of the cheek, lip, philtrum, ala, tip or columella, and wherever it is or has been there are tumours, varying in kind and degree. The only recourse is complete extirpation, something not always possible. It does happen that there is hardly enough healthy tissue left upon which to base a repair. This, surely, is a sufficient deterrent against its use, without going into the case-histories of a more startling nature, with their record of blindness, of embolism, and of malignancy. Nor is there much consolation from reflecting that in many cases the material was injected in the belief that the repair was the best and would be permanent.

Moreover, in the case cited, there is no need to resort to the use of paraffin, for if correction cannot be effected by a readjustment of the tissues themselves, it can be nicely and easily done by transferring a small bit of ear cartilage.

I am, Sir, yours faithfully,

New York, Oct. 28th, 1926. J. EASTMAN-SHEEHAN.

ASHAMED TO BEG.

To the Editor of THE LANCET.

SIR,—I also have had occasion to see consultants on my own behalf and that of members of my family and have had the same difficulties. Consultants—and they have unfortunately been many—have one and all been indefatigable in their kindness and generous of their skill but, though I am engaged wholly in laboratory work and almost divorced from patients, they all refuse fees. I recently asked a medical colleague to tell me what he would regard as a reasonable fee for one in my financial position for what he had done for me, and allow me to send a cheque to either Epsom College or the Royal Medical Benevolent Fund. We both welcomed it as a happy way out.

I am, Sir, yours faithfully,

Nov. 8th, 1926. MEDICO II.

To the Editor of THE LANCET.

SIR,—Your correspondent who describes himself in the issue of Nov. 6th as "ashamed to beg," has created for himself an entirely imaginary difficulty. He need not, as he puts it, "hesitate" to ask the help of any colleague, consultant, specialist or other. One is only proud that one's services or advice are sought, and happy that one can place them at the disposal of a colleague. His fear that a present will not be valued, or that the consultant will not be pleased, is morbid, and he should recognise it as such. At least a third of the men on the Register are in the same position, unable to send private cases to consultants. If the matter of a fee is really felt, a plan I have found acceptable might help. In such cases, where a fee is pressed, I ask the patient to become a subscriber to the Royal Medical Benevolent Fund, or to increase his subscription if he is one already. This avoids any question of indebtedness; I have accepted the fee, but on behalf of other and even less fortunate colleagues, and in the knowledge that the debt the patient feels he owes to his professional brethren he is paying to his professional brethren.

I am, Sir, yours faithfully,

Nov. 8th, 1926. CH.M.

To the Editor of THE LANCET.

SIR,—In reply to Medico's letter "Ashamed to Beg," our friend overlooks the broader and truer aspect.

All "consultants and specialists" have had help given them in their hours of need by their colleagues. As they are unable to repay the aid individually, they welcome the opportunity of helping the profession in general. This assistance is their only means of expressing their deep sense of gratitude.

I am, Sir, yours faithfully,

G. LENTHAL CHEATLE.

Harley-street, W., Nov. 9th, 1926.

HALOGEN ERUPTIONS WITH LESIONS ON THE TONGUE.

To the Editor of THE LANCET.

SIR,—In THE LANCET of Nov. 6th (p. 952) Prof. A. J. Hall records the case of a nephritic young woman, who, as a result of taking potassium iodide (only 12 gr. in all) developed a severe iodide eruption, one of the lesions being situated on the tongue. About three weeks later she developed pericarditis and died. He writes: "This occurrence of a lesion on the tongue, similar to those on the face, has, so far as I am aware, not been previously observed." In my paper on the Mycotic Type of Bromodermia and Iododermia in the *British Journal of Dermatology and Syphilis* (1923, xxxv., 169–180) Case 5 was that of a girl, aged 14 years, with granulomatous nodules on the tongue as well as lesions on the face and one leg, apparently due to iodides that she had been taking. In the hospital there was bronchitis, with evidence of nephritis, and pyrexia. She died and the necropsy showed (not very old) pericardial adhesion, much bronchitis, and "large white kidneys." She had

formerly had scarlet fever. The appearance of the tongue and face is illustrated by Fig. 4 of my paper. I knew of œdema of the tongue and glottis due to iodides, but not of any other case of iododermia in which the tongue showed lesions similar to those on the skin. After publishing the paper, however, I received a kind letter from a doctor including notes of a case of iododermia, with involvement of the tongue; the patient died with glottis œdema and broncho-pneumonia, but no mention of nephritis was made. Another doctor told me he had seen "variola-like" iodide eruptions in nephritic cases, including one case in which the tongue was involved. A third doctor wrote to me of a case of chronic nephritis in which a dose of potassium iodide was given to test the renal function. This was followed by the appearance of a granulomatous eruption on the face, tongue, hands, and other parts, with acute œdema of the eyelids and pyrexia. Pneumonic consolidation of the lungs and death followed. A fourth doctor told me of a man aged about 40 years, who was treated for rheumatoid troubles with moderate doses of potassium iodide. He developed a severe iodide eruption, together with ulcers on the tongue, and died with glottis œdema. That patient was not known to have renal disease. On the whole it seems to me most probable that renal disease, when present, has played an important rôle in such cases. In the two cases in which renal disease was not found or not mentioned, no post-mortem examination was, I believe, made.

A point in regard to the "mycotic" or "granulomatous" type of halogen eruptions—not alluded to by Prof. Hall or Dr. H. C. Semon (THE LANCET, Oct. 16th, p. 803)—is that in some cases (mostly before the days of the Wassermann reaction) the eruption has been regarded as possibly syphilitic and suitable for further iodide treatment.

I am, Sir, yours faithfully,

London, W., Nov. 8th, 1926. F. PARKES WEBER.

THE TREATMENT OF FLOUR.

To the Editor of THE LANCET.

SIR,—Various medical readers of THE LANCET have called my attention to the annotation on p. 718 of your issue of Oct. 2nd entitled the Adulteration of Food, which consists essentially of portions of a report by Mr. G. D. Elsdon, borough analyst to the Salford Health Committee. In the matter of flour, I do not accept the accuracy of the allegations contained therein, and it has been urged on me as a public duty that I should state plainly where in my view they are incorrect. I am somewhat in difficulty because the Government has referred the whole of the subject to a Departmental Committee which has investigated it most thoroughly. The manufacturers of substances used for flour treatment have laid their case in full before the Committee, so in fact have the millers, and evidence has also been given by bakers.

This Committee has not yet issued its report, and, consequently, the matter is still sub judice. In these circumstances I am precluded from dealing with Mr. Elsdon's statements in detail. I may, however, be permitted to say that Mr. Elsdon's suggestion, that in no other civilised country but England is flour treatment permitted, is not in accordance with facts. It is within the writer's personal knowledge that in Europe such flour treatment is successfully carried out in Germany, Holland, and several other countries. In America the same is done in the Argentine and the United States.

Although financially interested in certain processes of flour treatment, I venture to assure you that taking, for example, the form of such treatment which Mr. Elsdon apparently most reprobates—viz., that with persulphates—the fact is that it does not result in any detriment to the public, and that as a consequence the people are supplied with a pure loaf of better flavour and greater digestibility and consequently higher nutritive value.

I am, Sir, yours faithfully,

Hove, Sussex, Nov. 9th, 1926. WILLIAM JAGO.

*** The Minister of Health stated in Parliament on Nov. 9th that a Committee, alluded to by our correspondent, has had the various questions referred to it. The report of this Committee has been long expected.—ED. L.

THE SUPPLEMENTAL CHARTER OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

WE have received several letters accusing the Council of the College of dilatory methods in that effect has not been given to the supplemental charter in time to provide for the altered status of women Fellows and Members. The matter has been referred to in the lay press, strong terms being employed, showing unfamiliarity with the facts.

The supplemental charter of the Royal College of Surgeons of England was approved by the King in Council on July 26th, but was not officially sealed till August 19th, 1926, and was received by the College on August 24th. Arrangements to carry out the provisions of charters have to be made by by-laws and regulations, and it is not possible to formulate these immediately on the grant of a charter. In this case alterations have to be made in five by-laws, and the exact terms have to be settled by counsel.

No by-law of the College can be made, altered, or abrogated without the sanction of the Crown, or has any validity until approved by the Crown. Section III. of the by-laws defines the process of making, altering, or abrogating a by-law and requires that at least three meetings of the Council must be held for such a purpose. When the by-law has been finally approved and adopted by the Council, it has to be submitted to the Home Secretary for sanction, and before the Home Secretary sanctions the by-law it has to be examined and allowed by the Lord Chancellor and the Lord Chief Justice. Every by-law of the College bears the signatures of these three principal officers of the State. All this takes time, and the process of making a new by-law is seldom accomplished in much under six months.

The charter of 1926 does not in itself give women Fellows and Members the same status as men, but it makes it lawful for the College to give them the same status. Section XXVI. of the by-laws provides that in some particulars women Fellows and Members do not have the same rights and privileges as men, and that by-law must be altered before the College can exercise the power given it under the new charter of giving women Fellows and Members the same status as men holding the like diploma.

All this elaborate official procedure may seem cumbersome or unnecessary, but changes in the laws of the land must be made with every care or the consequences lead to troubles out of comparison greater than those which follow a delay, however much resented. There is no reason to doubt that steps are being taken by the College to effect the alteration of the by-law as quickly as possible.

ST. THOMAS'S HOSPITAL MEDICAL SCHOOL.—The following scholarships for 1926–27 have been awarded: Entrance Science Scholars: A. G. Sanders (£150), A. Kahan (£60); Entrance Arts Scholars: L. W. Lauste, A. Kennedy; Entrance University Scholar: G. W. Pickering (£100).

FINANCES OF ST. GEORGE'S HOSPITAL.—The ordinary income of this hospital is nearly £25,000 less than the ordinary expenditure, and there is now an overdraft of that amount. The joint treasurers, Lord Greville and Lord Maidstone, appeal for help in view of the fact that this year the revenue from legacies has failed to make up the deficit.

BIOLOGICAL STANDARDISATION OF REMEDIES.

DISCUSSION AT THE SECTION OF THERAPEUTICS AND PHARMACOLOGY OF THE ROYAL SOCIETY OF MEDICINE.

AT a meeting of this Section held on Nov. 9th, with Dr. GEORGE GRAHAM, the President, in the chair, Dr. H. H. DALE opened a discussion on the Biological Standardisation of Remedies. He said that every remedy with a potent and definite action should be supplied for therapeutic use with its activity indicated in some clear and intelligible notation. Where the active constituent was determinable by chemical methods this was simple, but there was a large and growing class of important remedies to which chemical standards were not applicable. In many of them the activity could be measured by a biological method. Everybody agreed on the importance of biologic units for measuring diphtheria antitoxin, insulin, and pituitary extract, but there had been a tendency to doubt the need for and value of such testing in the case of drugs which had long been used empirically. To the experimental worker the inevitable variation of the reaction of different patients, so far from making accurate measurement of a drug's activity less important, made it the more urgently necessary. His second principle was that the word "standardisation" had no proper use except in relation to some generally accepted standard. This seemed obvious and yet no official standards of activity, biologically determined, had hitherto been available in this country. They were, however, to come into force next year. Under these circumstances the manufacturers could not be blamed because preparations of widely different activities had been issued by different firms, but the natural result had been to strengthen conservative scepticism and bring the principle of biological standardisation into unjustifiable disrepute. The League of Nations had interested itself in the promotion of international uniformity, and already standards had been agreed upon for two sera, for insulin, for pituitary extract, and for salvarsan.

The Importance of Comparative Standardisation.

Dr. Dale urged the necessity for making the basis of all biological standards comparative. As a matter of practical experience it was not possible to define a unit for the activity of a remedy in absolute terms of some animal reaction. Ehrlich established the unit for diphtheria antitoxin in terms of a definite weight of an arbitrarily-chosen standard, and this method had stood the test of time. The first suggestion of measuring potent and variable drugs like digitalis by analogous methods had come from the late Prof. Cushny. Pharmacologists, however, for many years fell into error and ran a serious risk of discrediting their methods by tending to attribute too absolute a value to the determination of a limiting value such as a lethal dose. The drugs with which they dealt were different from the diphtheria antitoxin, where the aim of the test was to find the quantity of serum which left one lethal dose of toxin free and effective, so that an error even of 100 per cent. in the measurement of the free toxin involved comparatively little error in the determination of the neutralising quantity. Moreover, the animal used was merely the indicator in a titration, whereas for a "lethal dose" test the sensitiveness of the animal was a most important factor, and the measurement could not be accurately made on a small number of animals. The International Conference in Edinburgh in 1923 had decided to test the different methods recommended for standardising digitalis. The tests from many different countries showed complete agreement so long as the results were evaluated in comparison with a standard, but when an attempt was made to define the activity of any of the given specimens in absolute units of animal reaction the widest discrepancies appeared. In the early days of insulin attempts had been made to define a unit as the quantity needed to produce hypoglycæmic convulsions in a rabbit weighing 2 kg., but it soon became clear that this quantity varied enormously with different rabbits. Other laboratories tried to fix it by determining the dose needed to produce convulsions in a given proportion of mice, but found that small changes in diet and environment made large systematic differences in the reaction. Fortunately, the Edinburgh Conference had been able to intervene and fix a standard dry preparation.

The proper notation for the expression of the activity of a substance was one which employed an arbitrary but uniform and generally accepted unit of activity. Nobody would think of prescribing diphtheria antitoxin or insulin in drachms or cubic centimetres, but unfortunately dosage by volume of pituitary extract had grown up. There was no longer any excuse for the marketing of extracts varying, even theoretically, from 5 per cent. to 20 per cent. of the gland substance; a standard was now available.

The Nature of the Standard.

All the International Conferences had accepted the principle that a standard should consist of a specimen of the therapeutic substance itself, or of its essential active constituents, in a stable form. This was the only safe principle. The attempt to introduce such substances as histamine and potassium chloride as standards for pituitary extract had failed completely. The proper standard for digitalis was digitalis and a standard international sample of this drug had recently been completed by Prof. Magnus, of Utrecht.

It might seem strange to insist that the methods of biological comparison should be such as to give reasonably accurate measurement of the therapeutic activity, yet experience had shown that it was necessary to lay this down. The expression "biological standardisation" had been used for methods which could not be applied quantitatively to the measurement of anything, and without any evidence that the crude qualitative indications they gave had any relation to the therapeutic effect. The difficulty was to make clinical measurements of activity with any degree of precision, but it was not an insurmountable one, and there was room for much careful work.

Correspondence Between Laboratory and Clinical Tests.

It had been found that guarantee of freedom from undue toxicity was insufficient for neosalvarsan preparations as it was easy to produce products with a toxicity far below the official maximum, but with a therapeutic potency also lowered. A test for potency had, therefore, to be elaborated and the speaker and his co-workers had found that an estimation of the curative activity on mice infected with trypanosomiasis corresponded accurately with the estimation of efficacy in causing the disappearance of the spirochæte from superficial syphilitic lesions in man. Similar correspondence between laboratory and clinical tests had been found with digitalis and insulin. Laboratory workers must bear in mind the need for correlating their investigations with clinical work.

Dr. J. W. TREVAN dealt with the accuracy of certain well-established tests devised for all sorts of remedies which could not be standardised by chemical methods. Tests for insulin, digitalis, ergot, adrenalin, vitamins, and the ovarian hormone had reached such a stage that a definite value could be attributed to the degree of their accuracy. On the other hand, the methods described for testing parathyroid, thyroid, cannabis indica, and other substances were not supported by sufficient evidence for quantitative work. The errors which had to be considered were very largely due to the variability of the animals or organs used for the tests. He showed a chart illustrating, in a series of 250 frogs, the way in which they differed in the quantity of strophanthus required to stop the heart in systole in 12 hours. It took at least three times as much to kill some frogs as others. A similar chart showed the percentage of convulsions produced by different doses of insulin; here the variation was

even greater. The same difficulty arose with isolated organs.

Methods of Minimising the Error Due to Individual Variations.

The best and most accurate way of avoiding this difficulty was to use some reaction which was quickly reversible, so that the effect of the drug to be tested could be produced, washed out again, and repeated with a sample of some standard preparation. For instance, the rise of blood pressure in a cat bore a simple and constant relation to the dose of adrenalin injected, and the expected error could be worked out from the curve. In the middle of the curve it was found, both theoretically and practically, to be of the order of 6 per cent. The same sort of curve was obtained with pituitary extract, but here the sensitivity of the uterus did not remain constant throughout the experiment, so that the error was between 10 per cent. and 20 per cent. of the dose given. The method was also applicable to the artificial œstrus produced in castrated female rats by ovarian hormone, but the difficulty here was that a large increase in dose was necessary to produce a distinguishable increase in the œstrus. Recently it had been found that digitalis could also be tested in this way by its action on the rabbit's auricle in Ringer solution of a hydrogen-ion concentration of 7·4 obtained with boric acid mixture. An excessive dose produced a toxic effect which greatly increased the difficulty of washing out. Not all drugs, however, could be tested by a reversible reaction, and for some of these Clark's method for ergot was useful. Here two strips of uterine muscle were removed, as close together as possible, and tested in separate baths at the same time. A third way was to increase the number of tests, as, for instance, had been done with the action of digitalis on frogs and cats and of insulin on mice, and to some extent on rabbits. In the speaker's opinion the term "minimal lethal dose" had no fixed meaning and should be dropped in favour of the "average convulsive—or lethal—dose"—i.e., that obtained at about the middle of the range. Unfortunately, this varied from time to time, and might be twice as much on one day as on another, as animals showed periodic variations in sensitivity. Therefore, until a worker had demonstrated satisfactorily, through a very large series of experiments, that any given lethal dose method did not suffer from this "shift" in the average lethal dose, he must always assume that it might do so, and whenever he tested an unknown substance he must at the same time inject an equal number of animals with a standard preparation for comparison. This meant many experiments and many animals. It had appeared that certain antimonial preparations did not suffer from "shift," and possibly salvarsan was also free. The method of determining the error in a lethal dose experiment was complicated, but the expected and calculated errors had been found to correspond very well. If there were a 10 per cent. error it meant that 800 mice had to be injected, or, if digitalis were being tested on frogs, a 20 per cent. error meant the use of 80 animals.

Another method, which avoided this difficulty, was Hatcher's cat method for digitalis, wherein the drug was injected into a vein until the heart just stopped, and the dose was then calculated. The method of estimating the blood-sugar of a rabbit when testing insulin had the advantage that the rabbit could be used again a week later, but the sensitivity of rabbits varied from week to week. The number of animals necessary for the different tests in order to get an error of less than 25 per cent. was as follows: Adrenalin test, 1; pituitary test, 1; Clark's method for ergot, 1; auricle method for digitalis, 1; Hatcher method, 5; left ventricle of frog, 10; lymph sac of frog, 80; insulin in rabbits, 6; insulin in mice, 200. 80 frogs or 200 mice proved, however, only slightly more expensive than the smaller number of cats or rabbits, as the latter required careful watching all the time by skilled assistants.

The Value of the Laboratory Method to the Clinician.

Dr. J. H. BURN showed charts illustrating the relation between laboratory and clinical methods, saying that he doubted if practising physicians fully realised that the pharmacologist was not content merely to devise a method which measured something, but was actually measuring just what the clinician needed. Insulin had been tested by Marks's method on rabbits and on patients, and he showed the figures of the salvarsan preparations mentioned by Dr. Dale. The figures showed remarkable agreement in all cases. He also showed some unpublished figures from the Baltimore clinic in which different preparations of digitalis had been tested by clinicians and by the cat method, and suggested that the American investigators had succeeded in confirming laboratory investigations because they gave one single large dose instead of the small repeated administration more usual in this country.

The PRESIDENT observed that most clinicians had no idea how much work was done in order to make the preparations they used safe for them. Whatever drug was given certain people were going to have a violent idiosyncratic reaction and this could not be calculated. He hoped that this recent standardisation work would be incorporated in the new Pharmacopœia.

Dr. TREVAN and Dr. DALE, in reply, emphasised the necessity for setting up a standard for such substances as cod-liver oil, so that all workers could compare their preparations with one thing. The difficulty of vitamin standardisation did not seem to be properly realised.

Medical News.

ROYAL COLLEGE OF PHYSICIANS OF LONDON AND SURGEONS OF ENGLAND.—At the Final Examination of the Conjoint Board held from Oct. 5th to 26th, the following candidates were approved in the subjects indicated, but are not yet eligible for diplomas:—

Medicine.—F. Augsburger, Lausanne; G. H. Barendt Cambridge and St. Bart.'s; Winifred P. Brinckman, Bristol; C. P. Campion, Univ. Coll.; H. H. Cohen, London; E. Colin-Russ, Middlesex; C. L. Cope, Oxford and Univ. Coll.; C. Davies, Birmingham; Helen L. Dunn, Charing Cross; Evelyn Durrance, Royal Free; R. W. Eldridge, Liverpool; F. W. Gayford, Middlesex; Vivienne M. Gunson and V. F. Hall, King's Coll.; E. M. V. Hensman, Middlesex; R. C. Hodges, Westminster; V. Kathirgamatamby, London; M. S. Katre, Madras; F. Kellett, Cambridge and St. George's; S. M. Kharegat, St. Bart.'s; F. E. Loewy, Middlesex; E. M. Lourie, Univ. Coll.; W. S. Maclay, St. Bart.'s; J. K. Monro, London; Millicent Moseley, Birmingham; M. G. Nimatallah, London; Mary O'Leary, St. Mary's; R. K. Pillay, London; Aileen M. S. Pollock, St. Mary's; J. S. Rake, Guy's; Marion Ravell, Royal Free; S. Shalaby, London; R. Stanton, Westminster; W. H. Tandy, Birmingham; J. R. H. Towers, Leeds; C. G. Townsend, Cambridge and Guy's; Isabel Vallance, St. Mary's; W. D. Williams, London; Elsie B. Wright, Royal Free; and H. D. Zscherpel, St. Bart.'s.

Surgery.—H. Allan, Middlesex; Sophia A. P. Allen, Charing Cross; Gertrude Alphonso, Royal Free; R. G. Apthorpe, St. Thomas's; F. Augsburger, Lausanne and Lisbon; T. G. Benjamin, Guy's; H. Berliner, Univ. Coll.; K. J. Box, St. Thomas's; Winifred P. Brinckman, Bristol; A. H. Bruce, Guy's; R. Bruce, Leeds; R. W. Butler, St. Thomas's; R. L. Cheverton, Birmingham; Pamela M. G. Churchill, King's Coll.; E. T. Clifton, Guy's; W. A. Clark, St. Bart.'s; C. L. Cope, Univ. Coll.; N. Cox, Manchester; A. R. Culley, Cardiff; P. M. Davidson, London; T. G. Davies, L. F. Day, and J. Dean, St. Bart.'s; A. O. Dreosti, St. George's; J. Ellison, Leeds; A. G. Ensor, Guy's; D. K. Evans, Cardiff; Enid C. Evans, Westminster; K. M. Foster, Birmingham; H. S. Gaussen, Guy's; J. C. Gent, St. Mary's; N. Gindi, Birmingham; L. C. Griffin, St. Thomas's; T. R. Griffiths and J. H. Gubbin, St. Bart.'s; V. C. J. Harris, Manchester; J. A. Hartley, St. Thomas's; R. A. Haythornthwaite, Westminster; H. E. Houfton, St. Bart.'s; S. G. Irlam, London; N. Iskander, Birmingham; M. I. Jackson, Cardiff; D. N. R. Jones, St. Mary's; W. B. R. Jones, St. Thomas's; C. E. Kellett, Univ. Coll.; R. A. King, St. Mary's; G. Lee, St. Thomas's; P. G. Levick, St. Bart.'s; I. N. Lewis, St. George's; J. T. Lewis, Cardiff; A. J. Lomax, Manchester; E. M. Lourie, Univ. Coll.; Annie M. McGrath, Westminster; R. W. L. May, St. Thomas's; R. L. Midgley and H. M. Mikhail, Univ. Coll.; Margaret Mitchell, Birmingham; J. K. Monro, London; P. H. L. Moore, Sydney and St. George's; W. C. W. Nixon and Margaret B. Norman, St. Mary's; D. E. Oakley, St. Bart.'s; E. N. O'Neill, St. Mary's; Muriel V. Paton, Royal Free; G. E. B. Payne, Univ. Coll.; G. C. Pether,

Middlesex; R. S. Pilcher, Univ. Coll.; M. W. Platel, St. Bart.'s; W. P. Purvis, St. Thomas's; L. J. Rae, London; L. W. Rose and W. Rosenberg, Guy's; R. Rutherford, King's Coll.; C. G. A. Sadler, St. Mary's; S. W. Savage, Univ. Coll.; S. Segal, Westminster; L. A. P. Slinger, St. Bart.'s; H. M. S. Stanley, Cardiff; J. F. Stent, St. Thomas's; C. B. V. Tait, St. Bart.'s; H. D. Tonking, St. Thomas's; R. H. Tootill, Manchester; L. P. Tupling, Guy's; S. Tyagaraja, St. Thomas's; G. N. Unnithan, Univ. Coll.; E. S. Vergette, St. Bart.'s; J. Wasserstein, London; L. A. F. Wiles, St. Thomas's; H. M. Willoughby, St. Bart.'s; C. G. Windsor, St. Thomas's; and C. E. Woodrow, St. Bart.'s

Midwifery.—V. H. Addison, St. Bart.'s; N. H. Allen, Guy's; B. J. E. Anson, King's Coll.; Cecile H. D. Asher, Royal Free; N. Attygalle, Ceylon and Middlesex; A. Batty, Middlesex; H. Berliner, Univ. Coll.; Joan H. Blackledge, Royal Free; A. J. Blumenthal, Univ. Coll.; Eleanor D. Blunt, Royal Free; R. V. Bowles, Univ. Coll.; W. J. Branday, Birmingham; I. G. Briggs, London; Muriel Brighton and Helen R. B. Buck, Royal Free; H. J. Burrows, St. Bart.'s; E. Burton and W. A. Busby, London; R. W. Butler, St. Thomas's; Mildred Carpenter, Univ. Coll.; D. C. Carroll, London; C. H. A. Carty-Salmon, St. Bart.'s; M. Cohen, Middlesex; Mary C. E. Constantine, Royal Free; P. J. Cowin and W. V. Cruden, St. Bart.'s; Constance M. Cusden, Charing Cross; J. G. A. Davel, London; C. S. Davies, St. Bart.'s; W. N. Dickensen, St. Thomas's; C. W. L. Dodd, London; A. O. Dreosti, St. George's; Margaret R. Dunlop, Royal Free; H. G. Edmunds, Univ. Coll.; E. E. Elzawahry, Manchester; Geraldine W. Everett, Royal Free; F. M. M. Eyton-Jones, St. Bart.'s; Margaret C. Falconar, Royal Free and St. Mary's; R. V. Farr and K. M. Foster, Birmingham; J. P. M. Fraulo, Guy's; V. Freeman, Univ. Coll.; Mabel Cassells Freeston, Royal Free; K. T. Gajjar, Univ. Coll.; C. E. Gallagher, Guy's; J. H. P. Games, Univ. Coll.; R. J. S. Garrow, Leeds; B. H. Gibson, St. Bart.'s; R. D'A. Gifford, Birmingham; F. H. Gillett, St. Thomas's; J. L. Glover, Guy's; J. H. Gubbin, St. Bart.'s; Bridget S. P. Gurney, Royal Free; H. Hannesson, London; V. C. J. Harris, Manchester; W. R. E. Harrison, St. Bart.'s; Lilian M. J. Henry, King's Coll.; Laurel K. Heny, Royal Free; W. A. C. Hortor, Middlesex; H. E. Houfton, St. Bart.'s; P. Inwald, Middlesex; A. H. Jackson, Royal Free; Amy L. Jagger and T. E. James, Cardiff; D. N. Rocyn Jones, St. Mary's; W. P. Jones, Univ. Coll.; Lily A. Jörgensen, Royal Free; C. S. Kah, St. Thomas's; R. A. King, St. Mary's; Caroline M. Kingsmill, Royal Free and St. Mary's; H. J. Krichefski, Univ. Coll.; P. G. Levick, St. Bart.'s; O. I. Lewis, London; E. W. Lindeck, Univ. Coll.; Olive H. Lister, King's Coll.; Florence Louis, Royal Free; L. P. McBrien, St. Thomas's; D. J. MacMyn, King's Coll.; R. L. Midgley, Univ. Coll.; Mary M. Moller, Royal Free; J. K. Moore, Guy's; C. S. Morgan, St. Thomas's; O. N. Morris, King's Coll.; Gertrude M. Nicholson, Durham; H. G. Nimbalker and A. B. Nutt, Sheffield; D. E. Oakley, St. Bart.'s; Ethel E. M. Ogilvie, Royal Free; Greta K. Olsson, Westminster; Gwendoline D. Orlebar, Charing Cross; R. L. Osmaston, Univ. Coll.; M. N. Patel, London; N. F. Pearson, King's Coll.; A. P. Peeney, Manchester; E. U. H. Pentreath, St. Bart.'s; G. C. Pether, Middlesex; Aileen M. S. Pollock and Monica M. M. Power, St. Mary's; J. C. Preston, Manchester; W. P. Purvis, St. Thomas's; A. Rabinowitz, Guy's; L. J. Rae, London; J. S. Rake, Guy's; Marion Ravell, Royal Free; Dorothy K. Reynolds, King's Coll.; Enid H. Rockstro, Univ. Coll.; Pattie E. Rose, St. Mary's; P. H. Row, Madras and London; H. Royle, St. Bart.'s; R. Saran, Calcutta; H. R. D. Schofield, St. Mary's; I. Schoub, London; W. H. Scriven and Doris G. Sharvelle, King's Coll.; M. Shlosberg, Manchester; E. J. Silverman and E. Sladen, Middlesex; F. C. Smith, London; S. B. S. Smith, St. Bart.'s; P. D. B. Spence, Guy's; J. F. Stent, St. Thomas's; D. D. Stidston, St. Mary's; D. W. Stuart, King's Coll.; B. M. Sundaravadanan, Madras; C. B. V. Tait, St. Bart.'s; Olive M. Thomas, Royal Free; R. G. Thomas, St. Thomas's; Doris H. Tomes, Westminster; H. D. Tonking, St. Thomas's; Sybil E. Tremellen, King's Coll.; F. L. H. Voller, St. Thomas's; M. R. Wadia, Bombay; C. W. Walker, St. Thomas's; J. Walker, Leeds; G. A. B. Walters, St. Thomas's; Nora W. Wamsley, Charing Cross; W. G. H. Warner, St. Mary's; J. Wasserstein, London; Maeve Whelen, Royal Free; Edith V. E. Whidborne, King's Coll.; G. D. D. Wijesekere, Ceylon; W. D. Williams, London; H. M. Willoughby, St. Bart.'s; C. G. Windsor, St. Thomas's; Dorothy L. Woodroff, King's Coll.; C. E. Woodrow, St. Bart.'s; E. C. Wynne-Edwards, St. Thomas's; and Margaret I. Yeatman, Charing Cross.

ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH.—A quarterly meeting of the College was held on Nov. 2nd, Dr. George M. Robertson, the President, in the chair. Dr. Leybourne Stanley Patrick Davidson and Dr. William Edward Foggie took their seats as Fellows of the College. Dr. Ronald Gray Gordon, Dr. James Richan Drever, Dr. Alan Leonard Smith Tuke, and Dr. John Farquhar Christie were elected Fellows of the College. The Hill Pattison-Struthers Bursaries in anatomy and physiology and in clinical medicine were awarded to Hamish Gordon Somerville and Henry Boyd Martin respectively. The Wood Bursary was awarded to Joseph Peter Collie. The Licence of David William Anderson, which had been suspended on May 5th, 1925, was restored. At an extraordinary meeting of the College, held on the same date, the Licences of Edalji Jamshedji Treasuryvala and Kaikhushru Edalji Master were suspended sine die.

UNIVERSITY OF LONDON.—The University Medal in Branch VI. (Tropical Medicine) of the M.D. Examination, July, 1926, has been awarded to Richard Murchison Morris, of the London Hospital and the London School of Tropical Medicine.

University of London Lectures.—A course of two (advanced) lectures on Colour Vision will be given at University College, Gower-street, W.C. 1, by Prof. H. E. Roaf, at 5 P.M. on Wednesdays, Dec. 1st and 8th.—The Semon Lecture, 1926, entitled Nervous Affections of the Œsophagus, will be given in the lecture hall of the Royal Society of Medicine, 1, Wimpole-street, W., by Dr. A. Brown Kelly, at 5 P.M., on Thursday, Dec. 2nd.—A course of five lectures on the Influence of Environment on Bacteria will be given by Dr. F. W. Twort, superintendent of the Brown Institution, in the theatre of the Royal College of Surgeons, Lincoln's Inn-fields, W.C., at 4 P.M. on Monday and Tuesday, Dec. 6th and 7th, Thursday, Dec. 9th, and Monday and Tuesday, Dec. 13th and 14th. Admission to all these lectures will be free, without ticket.

ROYAL SANITARY INSTITUTE.—A sessional meeting is to be held on Saturday, Nov. 20th, in the Town Hall, Colchester, at 11 A.M., when there will be discussions on Rheumatism in School Children (Dr. R. H. Vercoe) and the Plan and Design of a Public Elementary School (Mr. E. S. Miles). Dr. Charles Porter will preside.

OPHTHALMOLOGICAL SOCIETY.—The annual congress of the Ophthalmological Society of the United Kingdom will be held at Liverpool from April 28th to 30th.

PEOPLE'S LEAGUE OF HEALTH.—Dr. Neill Hobhouse will lecture on Association of Ideas, Recognition, and Memory on Monday, Nov. 15th, at 6 P.M. at the rooms of the Medical Society of London, 11, Chandos-street, Cavendish-square, W. 1.

CENTENARY OF LAËNNEC.—The French Ambassador has informed H.M. Government that the centenary of Laënnec will be celebrated in Paris from Dec. 13th to 15th, and that Prof. Chauffard, of the Academy of Medicine at Paris, is in charge of the arrangements.

ROYAL INSTITUTE OF PUBLIC HEALTH.—The remaining lectures of the course on Problems of Personal and Public Health will be given at the Institute, 37, Russell-square, London, W.C., on Wednesdays at 4 P.M. as follows: Nov. 17th, Dr. R. H. Miller, the Problem of Rheumatism and Rheumatic Heart Disease in Children; Nov. 24th, Dr. C. W. Saleeby, From Heliotherapy to Heliohygiene; Dec. 1st, Dr. P. C. Varrier-Jones, Settlements for Tuberculous Workers; Dec. 8th, Lieut.-Colonel F. E. Fremantle, the Rôle of Parliament in Regard to Health Legislation.—The Harben lectures will be delivered in the lecture theatre of the Institute by Prof. W. W. C. Topley on Quantitative Experiments in the Study of Infection and Resistance, on Nov. 15th, 18th, and 22nd, at 4 P.M. No tickets of admission are required.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION.—On Thursday, Nov. 18th, at 5 P.M., Mr. Zachary Cope will lecture on Acute Intestinal Obstruction at the rooms of the Medical Society of London, 11, Chandos-street, Cavendish-square, W. On Friday, Nov. 19th, at 1 P.M., Mr. Charles Goulden will give a clinical demonstration in ophthalmology at the Royal London Ophthalmic Hospital. On the same date, at 2 P.M., Mr. Clifford Morson will give a demonstration in surgery at St. Peter's Hospital. The lecture and demonstrations will be open to the medical profession without fee. From Nov. 15th to Dec. 4th the Royal Waterloo Hospital will hold a course in medicine, surgery, and gynæcology, for which the fee will be three guineas. From the same date St. John's Hospital will hold a four weeks' course in dermatology; there will be clinical instruction and two lectures a week, and a series of practical demonstrations in pathology will be arranged. The staff of St. Mark's Hospital is undertaking a comprehensive course in Diseases of the Rectum from Nov. 22nd for one week. From Nov. 22nd and continuing for four weeks there will be a late afternoon course in neurology at the West End Hospital, 73, Welbeck-street, London. The London Temperance Hospital is holding a general practitioners' course (4.30–6 P.M.) from Nov. 29th to Dec. 11th. Courses in obstetrics can now be provided for at the Queen Charlotte's Hospital and the City of London Maternity Hospital. Practical courses in anæsthetics can also be arranged. Personal applications may now be made to the Fellowship of Medicine for the position of clinical assistant at the Samaritan Hospital for Women. Copies of all syllabuses, the General Course Programme, and of the *Post-Graduate Medical Journal* may be had from the Secretary of the Fellowship of Medicine.

ABERDEEN UNIVERSITY CLUB, LONDON.—The seventy-sixth half-yearly dinner will be held at Kettner's Restaurant, 29, Church-street, Shaftesbury-avenue, W. 1, on Thursday, Nov. 25th, at 7 for 7.30 P.M. Prof. W. Bulloch, F.R.S., will take the chair. Those who wish to attend should advise Dr. W. A. Milligan, 11, Upper Brook-street, W. 1, before Nov. 20th, who will be pleased to hear from any graduate of the University. The price of the ticket is 10s.

GLASGOW UNIVERSITY CLUB, LONDON.—This club will dine at the Trocadero Restaurant, Piccadilly, on Friday, Dec. 3rd, at 7.15 for 7.30 P.M. The chair will be taken by the Lord Rector (Sir Austen Chamberlain), and amongst the guests will be the Lord Chief Justice. Any Glasgow University men who, though not members of the club, desire to be present are requested to write to the Hon. Secretaries, 62, Harley House, N.W. 1.

KING'S COLLEGE HOSPITAL WAR MEMORIAL.—The Dean of King's College, the Rev. W. B. Matthews, D.D., last week dedicated two mural tablets to members of the staff who lost their lives in the war. The tablets, designed by Mr. W. A. Pite, the hospital architect, are on the west wall of the chapel and bear the names of 25 students, five nursing sisters, two men of the works department, and two porters.

VIENNA MEDICAL SCHOOL.—The syllabus of special medical courses arranged by the University of Vienna for the session 1926–27 has just been issued, and includes all the usual subjects. Persons attending these courses are exempted from the necessity of having their passports vised for Austria, provided they can produce a card of enrolment. All further information can be obtained from the Secretary, the Medical Courses, Schloesselgasse 22, Vienna 8.

CLOSING OF HARROGATE ROYAL BATH HOSPITAL.—This institution was closed last week on account of the difficulty of obtaining supplies of fuel adequate for the balneological treatment and the comfort of the patients, who have left. The waiting-list contains more than 100 names. It is hoped to reopen the hospital early in the New Year.

MEDICO-LEGAL SOCIETY.—A meeting of this society will be held at 11, Chandos-street, Cavendish-square, London, W., on Thursday, Dec. 2nd at 8.30 P.M., when a paper will be read by Prof. Harvey Littlejohn and Dr. Douglas Kerr, entitled Monoxide Poisoning: Its Increasing Medico-Legal Importance. A discussion will follow.—The society's annual dinner will be held at the Holborn Restaurant, London, W.C. 1, on Friday, Dec. 10th, at 7 for 7.15 P.M., when the President, the Right Hon. Lord Justice Atkin, will be in the chair. The members of the society are asked to communicate intention to be present and the number of guests they may bring to Mr. Ernest Goddard, hon. secretary of the society, 3, South-square, Gray's Inn, W.C. The price of the dinner is 14s. 6d., exclusive of wines.

CHILDREN'S HOSPITALS.—During the last week or two there has been remarkable activity in relation to the provision of hospital accommodation for sick children. Last week Princess Mary opened the Infants' Convalescent Home at Burnham, Bucks, which has been built as an offshoot of the Infants Hospital, Vincent-square, Westminster, of which she is President. Mr. Gomer Berry has defrayed the cost (£2700) of the freehold.—On Nov. 2nd Princess Louise, Duchess of Argyll, laid the foundation-stone of the Princess Louise Hospital for Children in North Kensington. This is a re-establishment of the Kensington Dispensary and Children's Hospital and will serve a population of nearly 100,000 in a district where there is no provision for sick children. It will accommodate about 50 in-patients and will include a dispensary for women.—The foundation-stone has also been laid of the new Royal Aberdeen Hospital for Sick Children, which is to be erected on a site of 16 acres at Forresterhill at a cost of £110,000. There are only three hospitals for sick children in Scotland, the other two being in Edinburgh and Glasgow. Prof. Matthew Hay states that this will be the best institution of its kind in the Kingdom.—Last week also there was opened a remodelled out-patient department at the Fleming Memorial Hospital for Children at Moor Edge, Newcastle-upon-Tyne.—Sir Claude Hill, Governor of the Isle of Man, has opened the "Sarah Jane Osborne Children's Ward" which has been added to Ramsey Cottage Hospital.—The Queen's Hospital for Children, Hackney-road, is in such serious financial difficulties that, unless a large sum of money is raised quickly, at least one half of the wards will have to be closed at the end of the year. Its 170 beds have long been insufficient and an appeal for £20,000 is being made.

THE Deputy Secretary to the Ministry of Health, Mr. E. R. Forber, C.B., C.B.E., has appointed Mr. D. C. L. Ward to be his private secretary.

EUGENICS SOCIETY.—Sir Bruce Bruce-Porter will preside at a meeting of this Society to be held at the London Day Training College, Southampton-row, W.C., on Wednesday, Nov. 17th, at 8 P.M., when the subjects of Mental and Physical Degeneration and Differential Birth-rate will be discussed.

SHROPSHIRE AND WALES EYE, EAR, AND THROAT HOSPITAL.—A new wing of this hospital was opened by Princess Mary last Saturday; it is named after her. There is no institution of the kind between Shrewsbury and the sea on the west; patients are received from as far away as Swansea and Aberystwyth, and its enlargement had become imperative.

ROYAL MEDICO-PSYCHOLOGICAL ASSOCIATION.—A quarterly meeting of this Association will be held on Tuesday, Nov. 16th, at the Horton Mental Hospital, Epsom, which will be open to inspection all day; other institutions in the neighbourhood may also be visited. The meeting will be held at 2 P.M., after luncheon, and at 3 P.M. Dr. P. K. McCowan and Dr. J. S. Harris will give a paper and clinical demonstration on Chronic Epidemic Encephalitis. As already announced, a special meeting of the Association will be held on Monday, Nov. 15th, at 4 P.M., in the house of the B.M.A., Tavistock-square, London, when Dr. Alfred Adler (Vienna) will give an address on the Cause and Prevention of Neurosis. Members and their friends are cordially invited.

DONATIONS AND BEQUESTS.—Sir Samuel Butler Provis, Whitehall-court, S.W., left £1000 to Queen's College, Cambridge, and £500 to the Chelsea Hospital for Women.—Mr. and Mrs. W. J. Courtauld, of Halstead, Essex, have given £1000 to endow a bed at Chelmsford Hospital.—Mr. Fred Needler, of Hull, has made a donation of £1000 to the Lord Mayor's Hospital Sunday Fund to commemorate the visit of the Prince of Wales to his firm's works.—The King has sent £500 to the West Norfolk and Lynn Hospital, the money being allocated from the admission fees to Sandringham grounds during the summer.—Mr. John Bullough, Over Hulton, Atherton, Lancs, besides other bequests, gave £500 to the Leigh Infirmary, the Mary Bullough Memorial Institute, £200 each to the Atherton Sick Nursing Association and the Atherton Guild of Help, and £2000 to his nurse.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

Opening of Autumn Session.

PARLIAMENT reassembled on Tuesday, Nov. 9th, for the autumn session.

Business Before Christmas.

Replying to Mr. CLYNES, Mr. BALDWIN (Prime Minister), said that among the Bills which the Government hoped to pass before the prorogation were the following: The Housing of Rural Workers Bill, the Mental Deficiency Bill, the Prisons (Scotland) Bill, the London University Bill, the Legitimacy Bill, the Lead Paint Poisoning Bill, the Local Authorities Bill, the Smoke Abatement Bill, the Coroners Amendment Bill, and the Births and Deaths Registration Bill. It was not proposed to proceed with the Factories (No. 2) Bill this session.

HOUSE OF LORDS.

TUESDAY, NOV. 9TH.

Protection for Juveniles.

Viscount ASTOR asked in what measures the Government proposed to give the protection promised on May 18th, 1926, to juveniles between the ages of 14 and 18 engaged in occupations at present unregulated by statute.

The EARL OF PLYMOUTH (Captain Gentleman-at-Arms) said that the new Factories Bill did not include the juveniles referred to. He did not think it could be so amended as to include them. He regretted that he could not give a very definite answer to Lord Astor's question, but the Government had not yet taken a decision on the matter. Nor had Parliament yet taken a decision on the Factories Bill, and the Government, while they had every sympathy with, and wished to improve the lot of, juveniles engaged in unregulated employment, felt that it would be premature to introduce legislation on that matter until the question of the conditions and hours of labour of young persons employed in factories had been settled.

HOUSE OF COMMONS.

TUESDAY, NOV. 9TH.

Pensioners and Hospital Treatment.

Sir CHARLES CAYZER asked the Minister of Pensions how many ex-Service men whose malady was admitted to be attributable to, or aggravated by, war service, were awaiting sanatorium or hospital treatment at the present time; if there was any accumulation of such waiting cases; and when his department expected to be able to deal with them. —Lieut.-Colonel G. F. STANLEY replied: The number of ex-Service men awaiting admission to sanatoria or hospitals was, at the end of September last (the latest date for which figures are available), 328. This number is well within the average weekly number of admissions to Ministry hospitals alone, and I am satisfied that there is no accumulation of cases awaiting treatment.

Medical Inspection of Dairy Farms.

Sir CHARLES CAYZER asked the Minister of Agriculture whether he was aware of the campaign now being promoted in many urban districts with the object of authorising all medical officers in any district to which milk was supplied to inspect the farm or farms from which such supplies originated; what was the attitude of his department on the matter; and whether he was aware of the objections from every standpoint of the dairying interest to such policy. —Sir KINGSLEY WOOD replied: My right hon. friend has received copies of resolutions passed by a number of urban authorities in the sense indicated by my hon. friend. My right hon. friend is aware of the objections of the dairying interest to the policy recommended in these resolutions, and he does not at present contemplate the introduction of legislation to amend the Milk and Dairies (Consolidation) Act, 1915, which now governs this matter.

Poor-law Statistics and Coal Disputes.

Mr. HERBERT WILLIAMS asked the Minister of Health whether he could give comparative statistics of the numbers of persons in receipt of Poor-law relief, and of the cost of such relief as a result of the disputes in the coal-mining industry which took place in the years 1893, 1898, 1921, and 1926.—Sir KINGSLEY WOOD, Parliamentary Secretary to the Ministry of Health, replied: It is estimated that in the course of the four disputes mentioned the following increases occurred in the number of persons in receipt of domiciliary relief and in the cost of such relief. It is impossible to state definitely that these increases were entirely due to the disputes or that they indicate the whole effect of the disputes upon pauperism.

(1) *Increase in Numbers.*

Period covered by dispute.	Maximum increase in numbers of persons in receipt of domiciliary relief in areas directly affected by the dispute.		Net increase in numbers of persons in receipt of domiciliary relief in England and Wales at the same date.	
	Number.	Percentage.	Number.	Percentage.
1893 (June to November)	2,270	11	25,489	5
1898 (end April to July)	43,751	155	32,200	6
1921 (April 1st to July 1st)	464,683	373	647,500	144
1926 (May 1st to date)*	1,162,592	337	1,266,095	126

* This estimate covers period ended Oct. 30th, 1926.

(2) *Increase in Cost of Relief.*—Records showing the cost of relief during the period of the earlier disputes are not available, but it is estimated that during the dispute in 1921 the cost of outdoor relief in money and kind in the areas directly affected increased by at least £850,000, As compared with the rate of expenditure in April, 1926, the cost of outdoor relief in money and kind was greater during the period from the beginning of May, 1926, to the end of October, 1926, by approximately £8,800,000 in the areas directly affected by the dispute.

Imported Machine-Skimmed Condensed Milk.

Mr. RYE asked the Minister of Health whether he was aware that machine-skimmed condensed milk, lacking in nutritive quality, was being imported into Great Britain in increased quantities; and, what steps, if any, he would take to ensure that such imported milk was not sold for infant consumption.—Sir KINGSLEY WOOD replied: My right hon. friend is aware that the imports of condensed machine-skimmed milk are increasing. The Condensed Milk Regulations require that every tin containing this article shall be abelled with the words "machine-skimmed" and "unfit for babies." He does not think that it is practicable to take any further steps to ensure that this article is not sold for infant consumption.

Farmers' Families and the Milk and Dairies Order.

Lieut.-Colonel ACLAND-TROYTE asked the Minister of Health whether he would take steps to exempt from the Milk and Dairies Order farmers who sold milk only to their own farm workers and their families.—Sir KINGSLEY WOOD replied: As at present advised my right hon. friend sees no reason for exempting from the requirements of the Order farmers who sell milk only to farm workers and their families. There seems no reason why such persons should not have the same protection as is accorded to the rest of the community by the Milk and Dairies Order.

The Sale of Impure Flour.

Mr. FORREST asked the President of the Board of Trade whether his attention had been drawn to the allegations regarding the impurity of the flour sold to the general public; and what, if any, steps he was taking or had taken in this matter.—Mr. NEVILLE CHAMBERLAIN replied: I am aware that it is a common practice to add certain chemical substances to flour with the object of modifying its baking properties. The question whether such additions are objectionable on grounds of health and what restrictions, if any, should be placed on them in the interest of the public health has been referred to a Departmental Committee for consideration and report.

Study Facilities for Indian Members of the I.M.S.

Colonel DAY asked the Under Secretary of State for India whether the claims of the Indian members of the Indian medical service, so far as they related to facilities for study, had received further consideration, and with what result. —Earl WINTERTON replied: My noble friend has recently sanctioned a scheme of which one of the objects is to provide certain passage facilities for Indian officers of the Indian medical service who desire to avail themselves of study leave in this country. I hope that particulars will be announced shortly.

Grant to University of London.

Sir W. DAVISON asked the Chancellor of the Exchequer whether any, and if so what, grant from public funds had recently been promised to the University of London; in what circumstances had such grant been promised; and what conditions had been attached to the same.—Mr. CHURCHILL, Chancellor of the Exchequer, replied: I promised in June last on behalf of His Majesty's Government, that we would be prepared within certain financial limits to ask Parliament to make provision for improved accommodation of the University, subject to approval by the Treasury of plans to be formulated by the Senate.

Medical Diary.

Information to be included in this column should reach us in proper form on Tuesday, and cannot appear if it reaches us later than the first post on Wednesday morning.

SOCIETIES.

ROYAL SOCIETY, Burlington House, Piccadilly, W.

THURSDAY, Nov. 18th.—4 P.M., Meeting to receive Report of Council. 4.30 P.M., *Papers to be read:* W. S. Patton and E. Hindle: Reports from the Royal Society's Kala-Azar Commission in China, Nos. 1–5 (communicated by Dr. H. H. Dale). Major Patton will review the work done and in progress by the Commission in China. *Papers to be read in title only:* R. Hill: The Chemical Nature of Hæmochromogen and its Carbon Monoxide Compound (communicated by Sir Frederick Hopkins). H. Gremels and R. Bodo: The Excretion of Uric Acid by the Kidney (communicated by Prof. E. H. Starling). C. H. Browning, J. B. Cohen, S. Ellingworth, and R. Gulbransen: The Antiseptic Properties of the Amino Derivatives of Styryl and Anil Quinoline. T. S. P. Strangeways and F. L. Hopwood: The Effects of X Rays upon Mitotic Cell Division in Tissue Cultures in vitro (communicated by Sir William Hardy). Sir Charles Sherrington and R. S. Creed: Observations on Concurrent Contraction of Flexor Muscles in the Flexion Reflex. S. B. Schryver and H. W. Buston: The Isolation of Some Hitherto Undescribed Products of Hydrolysis of Proteins, Part III. (communicated by Prof. V. H. Blackman). J. A. Crowther: The Action of X Rays on *Colpidium colpoda* (communicated by Sir William Hardy).

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

TUESDAY, Nov. 16th.—5.30 P.M., GENERAL MEETING OF FELLOWS. Ballot for election to the Fellowship. 8.30 P.M., PATHOLOGY. Papers: Dr. J. A. Murray: Delayed Successful Autoplasty of Carcinoma. Dr. J. G. Greenfield: Adanmantinoma of the Hypophysis

Cerebri. Dr. Aldo Castellani: (1) Notes on Some Little-known Intestinal Bacteria. (2) Further Observations on Certain Phenomena of Probable Symbiotic Origin.

WEDNESDAY.—5 P.M., HISTORY OF MEDICINE. Papers: Prof. William Wright: Mediæval Conception of the Anatomy and Physiology of the Central Nervous System. Dr. Arthur Davies: A Montpellier Diploma.

THURSDAY.—5 P.M., DERMATOLOGY. (Cases at 4 P.M.) ANNUAL DINNER OF THE SOCIETY: Hotel Victoria, 7.30 for 8 P.M.

FRIDAY.—8 P.M., OBSTETRICS AND GYNÆCOLOGY. Cases: Prof. Henry Briggs: Pregnancy and Ascites. Prof. Beckwith Whitehouse: Secondary Ovarian Carcinoma Treated by Transfusion of Maternal Blood and Injections of Radiated Ascitic Fluid. Paper: Prof. Louise McIlroy and Dr. Alfreda Baker: The Causes and Prevention of Antenatal, Intranatal, and Neonatal Death. 8.30 P.M., ELECTRO-THERAPEUTICS. Paper: Dr. Walter J. Turrell: The Physio-Chemical Action of Interrupted Currents in Relation to Their Therapeutic Effects.

ROYAL SOCIETY OF TROPICAL MEDICINE AND HYGIENE.

Owing to illness, Prof. Mühlens is unable to give his paper on Plasmoquine. In consequence of this, the Laboratory Meeting will be held at the London School of Hygiene and Tropical Medicine on Thursday, Nov. 18th, the chair to be taken at 8.15 P.M. The following, amongst others, will give demonstrations: Dr. H. B. Newham, Dr. P. H. Manson-Bahr, Dr. C. M. Wenyon, Dr. H. H. Scott, Dr. J. G. Thomson, Dr. P. A. Buxton, Dr. J. W. A. Cameron, Dr. Aldo Castellani, Dr. C. A. Hoare, Dr. A. C. Stevenson, and Dr. H. M. Shelley.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

ROYAL COLLEGE OF PHYSICIANS, Pall Mall East, S.W.

FRIDAY, Nov. 19th.—5 P.M., The Very Rev. Dean Inge: Racial Degeneration. (David Lloyd Roberts Lecture.)

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, W.

MONDAY, Nov. 15th, to SATURDAY, Nov. 20th.—FELLOWSHIP OF MEDICINE. Special lecture at the Medical Society of London, 11, Chandos-street, Cavendish-square, W. Thurs., 5 P.M., Mr. V. Z. Cope: Acute Intestinal Obstruction. Free to members of the medical profession.—ROYAL LONDON OPHTHALMIC HOSPITAL, City-road, E.C. Fri., 1 P.M., Mr. Goulden: Clinical Demonstration. Free to members of the medical profession.—ST. PETER'S HOSPITAL, Henrietta-street, W.C. Fri., 2 P.M., Mr. Clifford Morson: Clinical Demonstration. Free to members of the medical profession.—ROYAL WATERLOO HOSPITAL, Waterloo-road, S.E. Special course in Medicine, Surgery, and Gynæcology.—ST. JOHN'S HOSPITAL, Leicester-square. Special course in Dermatology. Practical demonstration in pathology if desired.—LONDON LOCK HOSPITAL, Dean-street. Clinical course in Venereal Diseases. Instruction in the Out-patient Department. Further information from the Secretary of the Fellowship of Medicine.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.

MONDAY, Nov. 15th.—2 P.M., Medical Cases in the Wards. 2.30 P.M. to 5 P.M., Medical, Surgical, and Gynæcological Clinics. Operations.

TUESDAY.—2.30 P.M. to 5 P.M., Medical, Surgical, Throat, Nose, and Ear Clinics. Operations.

WEDNESDAY.—2.30 P.M. to 5 P.M., Medical Skin and Eye Clinics. Operations.

THURSDAY.—2.30 P.M. to 5 P.M., Medical, Surgical, and Ear, Nose, and Throat Clinics. Operations.

FRIDAY.—2.30 P.M. to 5 P.M., Surgical, Medical, and Children's Diseases Clinics. Operations.

On Wednesday, Nov. 17th, and Friday, Nov. 19th, at 2.30 P.M., there will be special demonstrations of Dermatological and Medical Cases by Dr. W. Jenkins Oliver and Dr. L. R. Yealland respectively.

WEST LONDON POST-GRADUATE COLLEGE, West London Hospital, Hammersmith.

MONDAY, Nov. 15th.—11 A.M., Mr. Tyrrell Gray: Surgical Wards. 12 noon, Mr. Simmonds: Fractures and Applied Anatomy. 2 P.M., Dr. Scott Pinchin: Medical Out-patients.

TUESDAY.—11 A.M., Mr. Endean: Venereal Diseases. 12 noon, Dr. Burrell: Chest Cases. 2 P.M., Mr. Banks-Davis: Throat, Nose, and Ear Dept.

WEDNESDAY.—10.30 A.M., Dr. Burnford: Medical Wards. 2 P.M., Dr. Owen: Medical Out-patients. 2 P.M., Mr. Gibb: Eye Dept.

THUSRDAY.—11 A.M., Resident Assistant Surgeon: Surgical Wards. 2 P.M., Mr. MacDonald: Genito-Urinary Department. 2 P.M., Mr. Donald Armour: Operations.

FRIDAY.—10 A.M., Sir Henry Simson: Gynæcological Operations. 12.15 P.M., Dr. Pritchard: Modern Methods in Medicine. 2 P.M., Mr. Sinclair: Surgical Out-patients.

SATURDAY.—9.30 A.M., Dr. Burnford: Bacterial Therapy Department. 10 A.M. Dr. Saunders: Medical Diseases of Children. 10 A.M., Mr. Banks-Davis: Throat, Nose, and Ear Operations.

Daily, 10 A.M. to 5 P.M. Operations, Medical, Surgical, and Special Out-patients Departments, Operations. Saturday, 10 A.M. to 1 P.M.

UNIVERSITY COLLEGE, Gower-street, W.C.

WEDNESDAY, Nov. 10th.—5 P.M., Dr. C. H. Best: Insulin. (Second of four advanced lectures in Physiology.)

POST-GRADUATE HOSTEL, Imperial Hotel, Russell-square, W.C.

TUESDAY, Nov. 16th.—9 P.M., Prof. C. A. Pannett: Treatment of Gastric and Duodenal Ulcers.

FRIDAY.—9 P.M., Dr. Maule Horne: The Practitioner and the Public Health Man.

LONDON SCHOOL OF DERMATOLOGY, St. John's Hospital, 49, Leicester-square, W.C.

TUESDAY, Nov. 16th.—5 P.M., Dr. A. Whitfield: Diseases Due to Fungi (1).

THURSDAY.—6 P.M., Dr. J. T. Ingram: Pathology Demonstrations.

HOSPITAL FOR SICK CHILDREN, Great Ormond-street.

THURSDAY, Nov. 18th.—4 P.M., Dr. Poynton: Some Inspiring Cases of Rheumatism.

NATIONAL HOSPITAL, Queen-square, Bloomsbury, W.C.

MONDAY, Nov. 15th.—2 P.M., Dr. Hinds Howell: Out-patient Clinic. 3.30 P.M., Mr. Williamson-Noble: Optic Atrophy.

TUESDAY.—2 P.M., Dr. Walshe: Out-patient Clinic. 3.30 P.M. Mr. Armour: Head Injuries.

THURSDAY.—2 P.M., Dr. Kinnier Wilson: Out-patient Clinic. 3.30 P.M., Dr. Gordon Holmes: Cerebral Disturbances of Vision.

FRIDAY.—2 P.M., Dr. Adie: Out-patient Clinic. 3.30 P.M., Mr. Perkins: The Treatment of Poliomyelitis.

CENTRAL LONDON THROAT, NOSE, AND EAR HOSPITAL, Gray's Inn-road, W.C.

FRIDAY, Nov. 19th.—4 P.M., Mr. Armour Brown: Nasal Obstruction.

CHADWICK PUBLIC LECTURES.

MONDAY, Nov. 15th.—5.15 P.M. (in the Barnes Hall of the Royal Society of Medicine, 1, Wimpole-street, W.), Prof. H. J. Fleure: Racial Characters of the Human Skin and Racial Types in Relation to Health. (Malcolm Morris Memorial Lecture.)

ROYAL INSTITUTE OF PUBLIC HEALTH, 37, Russell-square, W.C.

WEDNESDAY, Nov. 17th.—4 P.M., Dr. R. H. Miller: The Problem of Rheumatism and Rheumatic Heart Disease in Children.

MANCHESTER ROYAL INFIRMARY POST-GRADUATE COURSES

TUESDAY, Nov. 16th.—4.15 P.M., Dr. A. Ramsbottom: Malignant Disease of the Lungs.

FRIDAY.—4.15 P.M., Mr. A. H. Burgess: Cancer of the Gastro-Intestinal Tract.

ST. MARGARET'S HOSPITAL FOR WOMEN, Acomb-street, Whitworth Park, Manchester.

WEDNESDAY, Nov. 17th.—4 P.M., Mr. A. C. Magian; The Use of X Rays in the Diagnosis of Pregnancy.

UNIVERSITY OF SHEFFIELD POST-GRADUATE CLINICS.

FRIDAY, Nov. 19th.—3.30 P.M., at the Royal Infirmary: Mr. Kerr: Chronic Diseases of the Maxillary Antrum.

ANCOATS HOSPITAL POST-GRADUATE COURSE.

THURSDAY, Nov. 18th.—4.15 P.M., Mr. F. Holt Diggle: Tonsillectomy.

JAMES MACKENZIE INSTITUTE FOR CLINICAL RESEARCH, St. Andrews.

TUESDAY, Nov. 16th.—4 P.M., Dr. Hector Charles Cameron: Some Forms of Acidosis in Children. Discussion to be opened by Dr. J. H. P. Paton.

Appointments.

BEDFORD, DAVIS EVAN, M.D. Lond., M.R.C.P. Lond., has been appointed Assistant Physician to the Middlesex Hospital, London.

COLVILLE, E. T., M.B., B.S. Durh., D.P.H., Medical Officer for the Ashington Urban area.

HERINGTON, C., M.B., B.S. Lond., D.P.H., Medical Officer of Health for Ilkeston.

Liverpool Heart Hospital: PAUL, F. T., F.R.C.S. Eng., Honorary Consulting Surgeon: BICKERTON, T. H., M.R.C.S., Honorary Consulting Ophthalmic Surgeon.

Certifying Surgeons under the Factory and Workshop Acts: RICHARDSON, J. C. R., M.B., Ch.B. Camb. (Witham, Essex); STEVENS, A. L. B., M.B., B.Ch. Oxf. (Thames District, Oxford); and SKELTON, J. B. G., L.R.C.P. Lond., M.R.C.S., D.P.H. (Gosport, Southampton).

Vacancies.

For further information refer to the advertisement columns.

Accrington, Victoria Hospital.—H.S. £150.

Admiralty.—Dental Surgeons for the Royal Navy.

Birmingham and Midland Homœopathic Hospital and Dispensary.—H.S. £150.

Brighton County Borough Mental Hospital, Hayward's Heath.—Second Asst. M.O. £300.

Brighton, Royal Sussex County Hospital.—Cas. H.S. £120.

Plymouth, South Devon and East Cornwall Hospital.—Hon. Asst. P.
Portsmouth, St. Mary's Infirmary, &c.—Third Asst. Res. M.O. £250.
Prescot Union Institution, Whiston.—Hon. Res. Asst. M.O. £300.
Royal College of Surgeons of England.—Election to Court of Examiners. Also Election of Examiner in Dental Surgery.
Royal Free Hospital, Gray's Inn-road, W.C.—Surg. Reg. £200. Med. and Gynæcological Regs. Each £100. Also H.S.'s., H.P., &c., £100 each.
St. Thomas's Hospital.—M.O. in Charge of Electro-Therapeutic Dept.
Shanghai Municipal Council, Public Health Dept.—Asst. Pathologist. Tls.600 per mensem.
Shrewsbury, Salop Mental Hospital.—Senior Asst. M.O. £500.
South Uist Parish and Northern Division.—M.O. and Pub. Vaccinator. £620.
Stoke-on-Trent, North Staffordshire Royal Infirmary.—H.P. £150.
Truro, Royal Cornwall Infirmary.—H.S. £170.
West London Hospital, Hammersmith, W.—Phys. Also H.S., H.P., Res. Asst. Cas. O. and Aural and Ophth. H.S. Each at rate of £100.

The Chief Inspector of Factories announces the following vacant appointments for Certifying Factory Surgeons: Chichester, Sussex; Littlebourne, Kent and Penicuik, Edinburgh.

Births, Marriages, and Deaths.

BIRTHS.

BATTEN.—On Oct. 30th, at Lyndhurst-road, Hampstead, the wife of Lindsey W. Batten, M.B., M.R.C.P., of a daughter.

DEATHS.

BRABANT.—On Nov. 3rd, at The Cottage Hospital, East Cowes, after a long illness, Thomas Hughes Brabant, M.R.C.S., L.R.C.P., aged 77.
CAIRD.—On Nov. 1st, at Edinburgh, suddenly, Francis Mitchell Caird, M.B., C.M., F.R.C.S.E., LL.D., of Royal-terrace, Emeritus Professor of the Regius Chair of Clinical Surgery, Edinburgh University.
GIRLING.—On Oct. 31st, at Southend-on-Sea, John Girling, M.D. Brussels, M.R.C.S. Eng., L.R.C.P. Lond., L.S.A. Lond., and late of the London Hospital, aged 64.
LANE.—On Nov. 4th at the Star and Garter Home, Richmond, after a long illness, patiently borne, James Ernest Lane, F.R.C.S., late Surgeon to St. Mary's Hospital and the Lock Hospital, London, aged 69.
LUCAS.—On Nov. 6th, at The Vinery, Bury St. Edmund's, Robert Harry Lucas, M.R.C.S., L.R.C.P.
SMITH.—On All Saints' Day, at Lower Clapton-road, Roland Smith, M.R.C.S., L.S.A., J.P., in his 76th year.
STUART.—On Nov. 1st (suddenly), at his residence, "Carneal," Knebworth, Herts, Robert Charles Stuart, M.B., B.Ch., J.P.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Comments, and Abstracts.

CARE OF THE FEEBLE-MINDED.

THE sixty-seventh annual report of the Royal Eastern Counties' Institution for the Mentally Defective, Colchester, contains much interesting information. The institution is supported by voluntary contributions and by the payments of patients, and is certified by the Board of Education, the Board of Control, and the Home Office. The main building is at Colchester, and adjoining it are schools and workshops, presented by the late Lord Peckover, a large farm, and separate blocks for the lower grade classes. In addition there is a special residential school for high-grade girls (Greenwood School, Halstead), similar schools for boys (East Hill House and Hillsleigh, Colchester), a special home for young women (Lexden House, Colchester), a home for five classes of adult men (Bridge Home, Witham), and the seaside home (Crossley House, Clacton-on-Sea), presented by Lord Somerleyton. The total accommodation is for 1070 patients and extensions are in contemplation to be paid for by the county councils of Essex, East and West Suffolk, and Cambridgeshire. The number under care on Jan. 1st last was 1081.

Many useful trades are successfully taught at the Peckover schools with the object of making the inmates as self-supporting as possible. All the furniture required and all the clothing—including dresses, suits, and boots—are made at the institution; large numbers of mats, brushes, baskets, and articles of wood-carving are also manufactured, and it is stated that orders can always be carried out. Some of the girls are employed in the laundry and both boys and girls are taught farm and garden work. Many other kinds of manual work are taught in the schools and useful leather and other bags and raffia baskets are made. The ability and enthusiasm with which the institution is carried on are evident and the report from a Commissioner of the Board of Control is highly favourable.

The medical superintendent, Dr. F. Douglas Turner, in his scheme for dealing with mental deficiency, favours a central institution as a sorting house, some patients being kept for training, some, of low grade, being sent to institutions of simpler type, whilst some high-grade cases, after training, pass under guardianship. In specially favourable circumstances these are allowed to go out on leave; others are retained in hostels, but sent out to work by day. Daily work is the ideal, but practical difficulties limit its application. He also gives many powerful arguments against sterilisation. During an investigation of 318 cases among the general population he found that in only 15 was a parent or a grandparent feeble-minded, and he quotes Dr. R. D. Clarkson as stating, in the Morison lectures for this year, that he had been able to discover only 6 out of 3500 cases in which the parents of mentally defective children had themselves been certified or certifiable as feeble-minded. These figures are in very sharp contrast with those commonly accepted, and Dr. Turner gives fully his reasons for believing them to be a truer estimate. The defectives who have children, he points out, are mostly high grade or border-line cases, and to enforce their sterilisation would be to throw a great onus on the medical profession with the chance of a very small and problematical gain.

The Movement in Scotland.

In connexion with Dr. Turner's report, it is interesting to note that in Scotland the movement for the better care and appropriate education of the feeble-minded is steadily gaining ground. In a recent address at the opening of extensions at the Special School at Balfour-place, Edinburgh, Mr. W. W. McKenzie, senior assistant secretary to the Scottish Education Department, said that the day of special classes in schools was over, and that the day for the policy of concentration had come. A movement being made by the Scottish Women Citizens to establish a colony for the permanent care of the feeble-minded is likely to bear fruit very soon. At the Balfour-place Special School training is successfully given in cobbling, woodwork, cookery, spinning, basketry, shirt-making, cardboard modelling, needle craft, and one or two other occupations. It is estimated roughly that, among school-children, feeble-mindedness occurs to the extent of 1 per cent., and for Edinburgh this would mean that the education authority must provide for at least 500 cases. But the difficulties at the early stages are, of course, only a small part of the problem; it is the ages after 16 that give trouble.

THIRTEEN FOREIGN DRUGS.

UNDER Section 10 (5) of the Finance Act, 1926, the Treasury may exempt from the Safeguarding of Industries Act, 1921, any article in respect of which the Board of Trade are satisfied that it is not made in any part of H.M. Dominions

in substantial quantities, and that it is not likely to be made within a reasonable period. Notice has been given by the Board of Trade that this is the case in regard to the following 13 drugs: Amidopyrin, barbitone, cocaine, cocaine hydrochloride, guaiacol carbonate, hydroquinone, methyl sulphonal, oxalic acid, phenacetin, phenazone, piperazine, salol, sulphonal. It is not a little remarkable that none of these important chemicals is made within the Empire and that the teachings of the war have so soon been forgotten on the necessity of maintaining the rudiments of self-preservation. But however ready the medical man may be to help in keeping the British manufacturer going, it is the chemist on whom primarily the onus rests, and nothing will be done until the home chemical industry decides that the production of essential drugs cannot be left to the foreigner.

AN IMPROPER INVITATION.

WE have received from certain physicians the following:—

91, Regent-street, London, W. 1.

DEAR DR. ———

We assume that you are interested in Ultra-Violet Light Therapy, and probably have many clients to whom you prescribe this new form of treatment. We therefore make no apology in drawing your attention to the Institute at the above address, which is near your consulting rooms, and is equipped with the latest types of Ultra-Violet Lamps.

A number of eminent Doctors who cannot afford the time to irradiate patients themselves pass on their clients to us, and we may say that we only treat cases under a doctor's prescription.

Naturally, we realise that you would require some monetary interest in the matter as a quid pro quo for passing your clients on to us, and we suggest offering you one-third of the fees collected from your patients. Our fees range from 7*s.* 6*d.* to £1 1*s.* per treatment, according to the client's status, and the dosage required. We are also prepared to give special rates for a course of treatment, 13 charged as 12.

The procedure which we have in mind is, that you would refer your patients to us with a prescription, marking on the prescription the fee to be charged.

Should you consider the proposition favourably, the writer would be very pleased to call upon you or meet you at 91, Regent-street by appointment to discuss the matter further.

Trusting that we may hear that you desire to co-operate with us in the scheme outlined above.

Yours very truly,
The PARKER SUNLIGHT INSTITUTE.

The recipients of this circular resent it, and the "eminent Doctors . . . . who . . . . pass on their clients" to the Parker Sunlight Institute may reconsider their policy when they see the suspicion to which it may give rise.

ACTINOTHERAPY AT GLASGOW.

IN our last issue (p. 988) it was erroneously stated that a demonstration of actinotherapy at the Robroyston Hospital was given by Dr. Kathleen Smith. This demonstration was in fact given by Dr. Alexander Smith, resident assistant physician to the hospital, and his remarks on fixation methods applied only to non-pulmonary tuberculosis. The confusion arose because Dr. Kathleen Smith acts at the Cochrane-street clinic, visited earlier in the morning.

MANUAL SELF-TREATMENT FOR CONSTIPATION.

WE cannot approve of the advice offered in a little book [1] designed to help sufferers from constipation to treat themselves. With many of the considerations advanced we can cordially agree—notably that we lack any scientific proof that uncivilised people are not troubled by constipation and that dietetic treatment is not always efficacious in curing it. But to recommend habitual insertion of the patient's unprotected vaselined finger into the rectum in order to clear out fæcal débris and to stimulate intestinal movements is to risk dangers which are even more difficult to combat than obstinate constipation. The reluctance of a medical man to make a rectal examination without a finger-stall is not due to fastidiousness but to the well-known difficulty of cleaning a finger after contamination with fæcal matter. This difficulty is not to be met by the suggestion that "the finger used, as well as both hands, should be carefully washed and scrubbed with hot water and soap, because the risk of accidental infection to self and others is slightly greater than in the ordinary wiping after a motion." The use of a rubber stall certainly diminishes the risk of contamination, but even if occasionally in cases of long-standing constipation a preliminary manual clearance must occasionally be made by the doctor, it need seldom be repeated. Any encouragement to young people to manipulate an erogenous zone must be strongly deprecated. Nowhere in this little pamphlet is any warning given that the practice might lead to the formation of bad habits much harder to cure by drugs, diet, or exercise than is constipation.

MILK PASTEURISATION IN ILLINOIS.

A RECENT issue of the *Illinois Health News* gives a detailed account of work done on the pasteurisation of milk in Illinois during the year 1926. No less than 98 per cent. of all the milk used in cities in the United States having a population of 500,000 or over is pasteurised. In Illinois an estimated average of three-fourths of the milk is pasteurised in cities with a population of 30,000 or over, exclusive of Chicago. In Chicago about 99 per cent. of the milk supply is pasteurised. It is agreed that pasteurisation, if not properly done, may give consumers a false sense of security. Until recently only a very few cities in Illinois attempted to supervise milk plants including pasteurisation plants, and there was practically no inspection or supervision by any State department. The Chicago Health Department has made regular inspections of milk pasteurisation plants since 1916, when steps were taken to enforce the pasteurisation ordinance adopted by the city in 1908; and during the year under review more systematic, thorough, and detailed inspections were started when the sanitary control of the city's milk supply was placed under the immediate charge of engineers and other technical experts. In 1925, in response to a demand by various dairy, health and other public agencies, a law known as the Milk Pasteurisation Plant Law was enacted, the main provisions of which may be summarised as follows:—

(1) Pasteurisation is defined as the process of heating milk or milk products to a temperature of at least 142° F., and holding at such temperature for not less than 30 minutes.

(2) Operators of pasteurisation plants must apply to the State Department of Public Health for a certificate of approval.

(3) The State Department of Public Health shall prepare minimum requirements for the construction, equipment, operation, and maintenance of pasteurisation plants.

(4) Certain provisions are made as to the sanitary quality of the raw milk which is to be pasteurised.

It has been found that the pasteurisation plant owners, with but few exceptions, have proceeded willingly and promptly to make any changes that were found to be necessary in order to comply with the minimum requirements, any owners not so complying being compelled to discontinue operating their pasteurisation equipment and labelling the milk "pasteurised." The minimum requirements are based on present knowledge regarding the subject, and are subject to changes and additions if further study shows the need for the same. Much research has been done to determine the efficiency of various commercial pasteurisers. The most recent research work was probably that which was carried out at Endicott, New York, which included studies of the efficiency of different types of equipment under actual commercial operating conditions, as a result of which several valuable recommendations were made.

Among the more important problems which still call for research and which are now being studied are those connected with: (1) satisfactory devices for recording the actual length of time for which the milk is held at the proper temperature; (2) the question of leaky valves; and (3) foam accumulating on the top of the milk, and splash on the covers which occurs in certain types of pasteurisers. If the splash or foam is not maintained at as high a temperature as the milk it is doubtful whether the entire product is properly pasteurised.

The passage and carrying out of the Milk Pasteurisation Plant Law has already brought about marked improvement in the quality of the milk supply. Since pasteurisation was never intended to be a means for making dirty milk safe, but rather for making a clean milk safer, special attention is called to the minimum requirements in regard to the cleanliness of the raw milk brought to the plants. Enforcement of the Pasteurisation Plant Law is intended to ensure a clean milk, pasteurisation being directed towards destroying any disease-producing organisms which may accidentally be in the raw milk even when all reasonable requirements have been fulfilled at the farms.

THE LATE DR. F. H. CROWDY.—On Oct. 26th Dr. Frederick Hamilton Crowdy died at Highgate at the age of 75. Educated at the University of Edinburgh, he qualified in 1875 and graduated M.D. in 1886. For a time he was acting surgeon to the St. John's Hospital, Newfoundland, but for the last 40 years or more he had been in general practice at Highgate. He was medical officer to the Santa Claus Home for Invalid Children at Highgate, and organised numerous meetings to help in its support.

An Address

ENTITLED

THROUGH THE MAZE OF MEDICINE.

Delivered at the Scientific Medical Conference, University of Rochester, N.Y., on Oct. 26th, 1926,

BY ANDREW BALFOUR, C.B., C.M.G., M.D. EDIN.,

DIRECTOR OF THE LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE.

AT the eleventh hour Dr. Rhees asked me if I would come to Rochester and deliver an address in the place of Dr. Charles Martin, Director of the Lister Institute, who, unfortunately, was unable to visit America. Faced by this honourable yet onerous task, I found myself somewhat in a dilemma, for pen had to be put to paper when crossing the Atlantic, when I would be divorced from nearly all works of reference. It was clear that a strictly scientific paper was an impossibility, for there was no means of verifying facts and figures. However, the Atlantic itself furnished a clue, for the thought of a great ship like the *Leviathan* threading its way, under guidance, through a maze of waters to a desired haven led me to think of the student of medicine. Not that I would for a moment compare the average medical student to the *Leviathan*. The latter is very rapid, luxurious, presumably out to make money, indeed, many things a medical student should not be, but just as a ship on her maiden voyage leaves a home port, traverses charted waters, encounters buffetings and difficulties, yet eventually gains her objective, so the medical student ventures forth upon what we may call the maze of medicine and usually, despite trials and troubles, chiefly in the shape of examinations, makes good and is let loose upon a confiding public.

A MEDICAL EDUCATION.

It, therefore, occurred to me that it might be well to trace his wanderings through the maze. The maze itself has been the subject of careful consideration and criticism by Sir George Newman, who, in his two masterly studies, "Some Notes on Medical Education in England," published in 1918, and "Recent Advances in Medical Education in England," which appeared in 1923, has said practically all that can be said upon the matter. The second memorandum is a brilliant and fascinating piece of work, philosophic and humane, yet practical and inspiring, wherein a wealth of illustration is employed. It is, indeed, a classic utterance. It would be presumptuous, as well as useless, for me to intrude into Newman's field but, as he views the maze from the standpoint of an expert and administrator, I think it may be of interest in the first place to try to stand in the shoes of the medical student and see how he, with his limited outlook, is impressed by his new surroundings. It is not easy to do so, at least for anyone who was a medical student many years ago, for it is hard to recapture the elusive past, and, in addition, the inexorable process of evolution has imposed changes and advances of which one is not fully cognisant.

In the second place, while Newman has in yet another brochure pressed for the permeation of the medical curriculum with the preventive idea, and has indicated on broad lines how this should be accomplished, there would seem to be room for discussing in some little detail this new guide-rope which it is desired to introduce into the maze, this guiding principle which is intended to lead the student of to-day and to-morrow towards an objective, differing in some ways from that upon which the ambition of his predecessors has been set, an objective designed to make him not only a better doctor, but a more useful citizen, and to enlist his brains and knowledge in the service of the State, as a guardian of the public health.

Now it is a strange thing how little the lay public realise all that is comprised in a medical education. I fancy the parents who pay the fees are better acquainted with its magnitude, if not its complexities, than anyone else. Years ago at Khartoum, in the Sudan, Lord Kitchener paid a visit to the Gordon Memorial College, and along with Mr. (now Sir James) Currie I had an interview with him. He declared himself satisfied with what was being done at the Wellcome Tropical Research Laboratories of the Sudan Government, and asked if I thought the native students were profiting by the education given them at the College which was, in fact, really a secondary school. I said I thought they had made very good progress and had been well grounded. "Very well," he remarked, "I want you to go a stage further and turn out native medical officers. I give you two years in which to do it." "What you ask is impossible," I replied. "The word impossible is not in my vocabulary," he said, very emphatically. "Nor, as a rule, Sir, is it in mine," I ventured to retort, "but in this case what you ask *is* impossible. Do you know what course these boys would have to go through?" "Tell me," he said, and I told him in detail and could see the surprise come into his impassive countenance. It would take too long to recount our conversation, which had its humorous side. Suffice to say that Lord Kitchener abandoned his idea for the time being. However, as you may know, in memory of that great soldier and organiser there now exists a medical school in Khartoum where the Sudanese are trained to be doctors, but the curriculum is not limited to two years.

At present, however, I am not so much concerned with the length of the medical curriculum, which would seem to have reached its limit, as with its object and its general effect upon the student who, greatly daring if he only knew it, plunges sometimes unheedingly and thoughtlessly into *res medicæ*. I find myself a little at a loss in speaking to you, for I am not fully acquainted with the details of medical education in the United States. True, I have studied Flexner's book, I have also read "Martin Arrowsmith," and pondered over it, but I take it that Sinclair Lewis is scarcely an authority on medical education, although he can portray effectively certain aspects of it.

Hence, in dealing with the maze of medicine I have in mind rather the course of studies pursued by the medical students in the schools and universities of Great Britain, but believe that this does not greatly differ from that followed in the best centres of medical education in this country, while, from the point of view of the effect of his studies on the student, human nature, I take it, is much the same all the world over, and in any case there is a measure of kinship between the sons of the United States and those of Great Britain which suggests that their viewpoints cannot be vastly dissimilar. Speaking generally, it may be said that in both countries the medical student passes through the maze, guided on broad lines by the Dean of the Faculty, in details by his teachers, in many things by his fellow-seekers after knowledge, and that, at present, the link which binds together, often very loosely, the various subjects he has to study, is of a biological nature. His outlook is coloured by biology, using the word in its widest sense, although he himself may not be conscious of it.

THE STUDENT'S FIRST IMPRESSIONS.

For the purposes of our argument let us take the young student who has done little or no biology at school, and who, therefore, on beginning medicine, has to take up botany and zoology. He finds himself in a new world, the world of life viewed from the standpoint of the scientist. It is difficult for him to adjust his ideas. Not only are the terms used strange to him, the processes employed novel, the new facts a revelation, but, unless his teachers are very wise men, he sees at first everything as through a glass darkly, and is inclined to ask, "What's the use of all this to a doctor?" Botany proves, as a rule, more irksome than zoology, for vascular bundles do not appeal to him, and the study of natural

orders seems a mere waste of time. I think as a rule he appreciates the value of the training in technique in the practical work of the laboratory, but field excursions, save as an outing, are not attractive. I have often heard a student complain that he was taught all about the insides of plants and how to classify them, but was never told how to recognise the common trees and shrubs and flowers of his own country. This shows that the medical student tends to look upon botany, not as a means to an end, but as a well-defined subject, the cultivation of which should lead to botanical fruits. Even though he is studying zoology along with it, he does not see that, as Newman says, the two subjects are complementary to one another. Still less does he grasp the part that botany plays in the general scheme of his education, though it is significant that his interest quickens when those lowly forms of vegetable life, the bacteria, are presented to him, and when he is introduced to plants with medicinal and poisonous properties.

Whether it was due to the fact that I was not well taught, or that, having commenced the study of medicine at the age of 16, my intelligence was at fault, I cannot say, but I remember getting one of the shocks of my life at a zoological demonstration when the man sitting next to me nudged me in the ribs and said in a loud whisper, "That's a human tongue!" It was not only that I was brought unexpectedly for the first time into contact with the human cadaver or a portion of it, though I remember that my imagination ran riot about that tongue and its whilom possessor, but that I suddenly realised there was a close link between man and the brute creation. The human tongue, being comparatively large, was being used to demonstrate certain features of a rabbit's tongue, and ever since I have thought that while, as a rule, comparative anatomy is made to pave the way towards human anatomy, it would be well at times to reverse the process in a student's first year and, by making use of human parts, to teach the great lesson of evolution and relationship.

How important it is at this stage for the student to become familiar with Darwin's "Origin of Species"! Without it, even when well taught, he is apt to miss the true significance of his zoological studies, and, as Milton has it, "in wandering mazes lost" perceive no end. Says Newman, "if the medical man be not a biologist he is nothing," but too often he gets little chance of becoming a true biologist, being wearied by "types." He passes from the earth-worm to the snail, from the snail to the frog, from the frog to the skate and dog-fish, thence to the rabbit, and is apt to regard such as a delimited stage in his progress to an examination, rather than as an integral part of his life's work. True, things are changing for the better, but even yet the student tends to grope blindly, content to meet the immediate future.

The First Year Subjects Fundamental.

The teaching of physics, apart from biophysics, is nowadays very largely a function of the secondary school. I will not discuss the student's attitude towards it, but hope later to consider how it may be made the means of impressing the preventive idea upon his plastic mind. There are medical students who take kindly to chemistry. They are usually men with a mathematical bent, to whom the exactitude of the science appeals. To many chemistry is summed up in the word "stinks." In the past I think chemistry more than any subject has been divorced from medicine. It is true the student comes across substances which figure in the Pharmacopœia or are used as poisons, and rejoices accordingly. It is true he learns something of chemistry in industrial life and hears something about the chemical aspect of trade hazards, but, until recently, he was not taught to realise that chemistry in some form or other will follow him all through his course. If biology is the foundation of medicine, as Newman asserts, chemistry is one of its main props. Happy the first-year student who has, as at Edinburgh, a course of medical chemistry provided for him, arranged as a preparation for a future course of physiological chemistry. Too often the student views chemistry as a stumbling-block. His one desire is to get through with it and take up "real" subjects, as he calls them. To a certain extent attracted by the practical work which has something of the occult in it, he yet shies at equations as a horse at a gate, and resolves that, if only he passes, he will relegate the subject to the limbo of forgotten things. It may be that this is no longer the case, but it was so in my day, and there were I think, few students who understood that the subjects of their first year—chemistry, physics, and biology—were fundamentals, and represented the platform on which had to be built that training in science, in scientific thought and method, which is essential if medicine is to be other than mere empiricism and quackery.

Training in Anatomy.

Anatomy comes next, and in all probability the effect of the first contact of the student with the dissecting-room is never wholly effaced. Some men tremble without the door, others of tougher fibre betray no trepidation, but though, ere long, students may, as at Cambridge, speak lightly of "the meaters," to many the anatomy rooms mean their first contact with death. For a space there is a mystery about the sheeted figures, so stiff and silent, and though it passes, I am inclined to think his experience of them gives the "medico" his first sense of power. He begins to imagine that he is set apart for special work. When he dons his apron and takes in hand the scalpel he feels the rubicon is passed, and that he has in some measure become a priest of the craft of healing.

As the wonders of the human body are revealed anatomy becomes so engrossing that the student is apt to become unduly immersed in details. He has got hold of facts, and for a time their memorising seems to him a satisfactory and excellent thing. There is danger of the anatomy room becoming a mere valley, both of dry bones and dry facts with no quickening influence, nothing to link it to other branches of study. Newman, Keith, and others have dealt fully with this peril and its remedy, but it may not be easy to wean the student from the habit, easily acquired, of amassing facts and forgetting principles. Does the study of anatomy coarsen the mind? In some cases this would seem to be the case, for a time at least. Familiarity with the dead may breed some contempt for the living, but there are counteracting influences, and, to any student worth his salt, the marvels revealed by dissection should eventually bring a sense of humility and admiration, coupled possibly with wonder and pity that so delicate a mechanism as the human body is doomed to destruction and decay.

Physiology the Institutes of Medicine.

I have always thought that my old teacher, William Rutherford, "Bilirubin" as he was nicknamed after the bile-pigment he discovered, was in the right when he insisted on calling his subject the "Institutes of Medicine" instead of physiology. If physiology were always so regarded and taught the student would find this part of the maze easier than he usually does, and would perceive light ahead. If the maze be properly constituted there should not only be light ahead, but a certain refulgence behind him, proceeding from those parts of the maze he has already traversed. All the subjects he has been through should, as it were, unite in casting a beam of light on physiology, for here the student, now familiar with the dead body, contrasts it with the living. I think that apart from the histological side of the study, no subject of the course is at first so bewildering as physiology. There are so many side lines. The student has not only to grasp the mechanism and aim of the functions of the body as a whole, but, let us hope, with some recollection of physics in his mind, he must apply that subject to life and movement and consider also various

electrical reactions of the tissues. Physiological chemistry, or, as nowadays we may term it, biochemistry, which includes metabolism and endocrinology, will soon remind him that the time spent on chemistry, especially in its organic aspects, has not been wasted. Biomechanics will again remind him of his physics and will couple his physical with his anatomical knowledge. The physiology of the special senses will take his mind back to the anatomy theatre and the dissecting-room, and will once more show him how a knowledge of physics is essential to the proper understanding of such delicate mechanisms as, let us say, the eye and the ear, while his excursions into the comparatively young but all-important science of psychology should make him realise that while all thought processes centre in the brain which he has sliced and teased and sectioned, there is something intangible and elusive which, fortunately for himself, he can now liken to the wireless, and which may give him a wider conception of man's meaning and future. Lastly, when he applies his physiological knowledge in the laboratory upon the frog, upon the mammalia, there will dawn upon him a sense of the marvellous scheme of life, of its completeness as well as of its variety, of its inter-relations, of its correlations, of the smoothness and elasticity with which the body functions, of its extreme delicacy, of its marvellous strength, of its recuperative power.

Physiology is like a central chamber in the maze wherein all the other tracts he has been exploiting meet and mingle, and from which other tracts emerge. At first, confused by its very spaciousness, the student struggles to grasp its significance, but once he has got to grips with it his future is, or should be, secure, for, from this rallying ground, light beams along every tortuous out-going channel of the maze of medicine and more especially penetrates those which hear the designation "clinical."

The Principles of Pathology.

"Bugs" and "Drugs" are what the irreverent student sometimes calls the two subjects to which he is introduced when anatomy and physiology are behind him. It is rather significant that he classes pathology under "bugs," giving prominence to its bacteriological side. If he imagines, however, that bacteria and bacterial processes dominate the whole of pathology he will have a rude awakening. Sir Arthur Keith, in a recent lecture, recommended the student to pay an occasional visit to the post-mortem room while studying anatomy. It was sage advice, but most students never see what have been called the "doctor's failures," those tragic forms from the wards, until they have begun to wander through that part of the maze, a very large and intricate part, where they learn about tiny visible and invisible foes of man and discover what a mess disease can make of the form and functions of the wonderful mechanism of which they themselves are examples. The student, as a rule, takes kindly to this "science of morbid processes," as Newman aptly names it. For one thing, the bacteria are interesting and tangible. Most folk have a little of the farmer or hunter about them, relics of ancient days and forbears, and so it is pleasant to cultivate cocci and bacilli and to search for them in the blood and organs of some hapless guinea-pig or rat. For another the student renews his acquaintance with the pathogenic protozoa, parasitic worms, and noxious insects, is reminded of their complex life-cycles, and begins to understand how important they are, especially in the romantic domain of tropical medicine. Yet again he sees under the microscope sections of tissues with which he is familiar, altered sometimes out of all knowledge, while in the cadaver he witnesses the gross manifestations of disease. If his course is well ordered, however, he will also be given an opportunity of studying pathology in the living. Prof. Dean, of Cambridge, has said with truth, "Pathology, if it is to be the useful reality it ought to be to the student and graduate, must be learned in the wards, as well as in the post-mortem room and the laboratory." This, therefore, is a very interesting stage in the journey through the maze, for the student comes in contact for the first time with the living patient, and he also handles and sees the human shell from which the vital spark has but recently fled.

Preparation for Clinical Work.

It is true that if, like a wise man, he has taken some more of Sir Arthur Keith's advice, he will have already attended an operation or two in order to extend his anatomical experiences, but that is not quite the same thing as standing by the bedside of a patient and noting, perhaps, how yellow is his skin and that there is an ominous fullness in the right hypochondrium below the costal margin. This first incursion into wards and dead house cannot fail to leave its mark on the student's mind. Well it is for him, if now, and later when his clinical work commences, the humane side of him comes uppermost. There is a type, hard and keenly scientific, which comes to look upon the patient as a case, even as a museum specimen. This type may make a good pathologist, but he will never be a great doctor. No man can be a successful clinician if he is void of sympathy, and if he does not consider his client both from the psychical and the physical standpoint.

One cannot follow this section of the maze throughout all its ramifications, but the student will find once again that chemistry comes into the picture, and that from the diseases of the lower animals he may learn much that has a bearing on human pathology. "Drugs," in the old sense of the word, have gone out of fashion. We live in a world of tablets, of vaccines and sera, of endocrine preparations, of diet restrictions. We have harnessed the sun to our own uses, and even imitate the lord of light. Electricity and radium are drugs nowadays, and there are various other developments of which the student must have more than a smattering. Thirty or forty years ago he found the materia medica part of the maze simple enough but more than a trifle dull. Now he certainly cannot complain for lack of variety and presumably he appreciates the fact that both pharmacology and therapeutics are linked up with his previous studies, and most strongly linked by the biological chain. And so, gradually, in some ways almost insensibly prepared for it, the student reaches the most fascinating but the most intricate part of the maze of medicine. In some of the British schools he passes first of all through a kind of intercepting chamber, devoted to purposes of coördination, a place where he gets a breather before his final plunge, can take stock of his surroundings, and of his past, and not only have a refresher course in anatomy, physiology, and pathology, as applied to medicine and surgery, but undergo a short period of training in clinical methods, including case-taking, to fit him for his immediate duties. In my day at Edinburgh this took the form of what were called clinical tutorials, which were held in the evening, and the students found them most helpful, even though they did not precede, but were concurrent with, the work in the wards. Now the idea has undergone great expansion and modification, and it must be infinitely easier for the student to approach the bedside. In the old days some of us, young and callous, suddenly plunged into surgical wards as dressers in our second year of the maze, felt uncomfortably like humbugs, and, though possibly we did no great harm, it is unlikely either we or our cases derived much benefit from the contact.

At this stage the student, unless warned, is apt to forget that he is no longer dealing with disease as a separate entity, but with disease which has invaded not only the human organism, but a personality. He must be taught to think not in terms of the disease but of his patient, and for that purpose he must realise that the person, now sick, is a product of his past environment, which has probably been complex, and that the patient, himself complex, may, or probably will, so modify the disease which has laid

hold upon him that its bold outlines as recalled from pathological studies will no longer be apparent. If he does not grasp the significance of this truth, and still more the fact that vital processes control drug actions, he will certainly go astray, especially when he starts to treat his cases. In this part of the maze he will, so to speak, bump up against both in-patients and out-patients, and he will also learn the value of nursing and of the efficient nurse. Not a few medical students regard the staff nurse with respectful awe second only to that in which they hold the "chief." The same feeling, however, does not usually extend to the probationer.

What of surgery? I remember it was quite a considerable time before I plucked up courage to go and see an operation, even though I hail from Scotland and had paid a hospital fee! Eventually I selected for my first plunge an enucleation of the eyeball, which I witnessed (save the mark) from a back seat in a large theatre. I take it quite a few students suffer from a similar timidity. What saved me was an amputation of the leg, which had perforce to be performed on an accident case during a crowded out-patient clinic from which I could not escape, and what helped me through the ordeal, for such it seemed, was my knowledge of anatomy. Here is an illustration of another way in which the value of linking subjects together can be manifest. Pray pardon these personal reminiscences. I make use of them only to give point to the arguments advanced.

In connexion with his surgical course the student is now trained in the nature and use of anæsthetics in a manner which did not previously exist. To many a man this must come as a boon and a blessing. It is no use, indeed, it is fatal, to leave any branch of practical work to the student's own initiative. There are some who have none, there are others in whom diffidence masters initiative, there are yet others who are the slaves of slackness.

THE MAZE THICKENS.

It is now that the student discovers that he must begin to reason in a way he has never done before. He finds himself up against most difficult problems, and very soon discovers that guessing is dangerous. He has to proceed along definite lines of inquiry and exclusion, and, as he does so, he will find again how all his stores of knowledge can now be drawn upon as occasion requires, and if he has the necessary breadth of vision it will be apparent to him why he has had to struggle so long in the intricacies of the maze, and he will begin to feel that not far off he will round the last corner and be free. He is fortunate if, once he has made some progress in his clinical studies, he gets a chance to put precept and observation into practice as, say, in dispensary practice under supervision, where he comes into contact with his patients in their own homes, and learns more of human nature, its makeshifts, trials, sorrows, vices, and virtues, than he can in any hospital ward or out-patient department. There, also, perhaps, for the first time he will get some inkling of social problems and realise the need for safeguarding the public health. Dispensary practice or no, he will have to visit the humble homes when he attends obstetric cases, and it may be said that almost a new world opens to him when he enters, perhaps fearfully, that part of the maze which traverses the fields of midwifery and gynæcology. To many a male student this is a difficult and not altogether congenial part of his wanderings, but possibly that is because there has, in the past, been a comparative failure in the methods of teaching it. How this may be remedied is set forth by Newman in the second of his treatises and, as I must return, though briefly, to the subject a little later, I need not here say more. My own experience is so limited that it is scarcely fitting that I should enlarge upon the theme.

I think most students enjoy the short course in medical jurisprudence. There is an element of the dramatic in it, with tragedy well to the fore. Quite apart from its medical aspects, which can be rendered very impressive if linked up with the work of a police surgeon, the student, now probably approaching man's estate, has an opportunity of learning something about the machinery of law, and criminal law is infinitely more interesting than public health legislation, concerning which at this time he also gets an inkling.

He is fortunate if he gets more than an inkling into the huge subject of preventive medicine. However, even at this late stage in his medical career, he may have an opportunity of grasping the cardinal facts that curative and preventive medicine cannot be divorced from one another, and that, as a practitioner, he will have duties both towards his patients and the State which it is imperative that he should fulfil to the best of his ability.

THE STUDY OF SPECIAL SUBJECTS.

No good object will be served by talking about the study of special subjects, amongst which one does *not* class diseases of children, for that should be an integral part of the medical curriculum. In practice perhaps half the doctor's patients will be "sick kids," and as, for the elucidation of their complaints, it is necessary to know how to approach and handle them, and as there are maladies peculiar to childhood, and as ordinary diseases assume in children forms different from those they present in the adult, and as the doctor must treat the patient and not the disease, it seems criminal to grant a medical degree to any man who has not been instructed in pediatrics. Furthermore, the contact with child life is for the student a useful, and let us hope, usually a beneficial experience which will stand him in good stead in years to come.

As he emerges into the open ready for cap and gown, degree, or diploma, relieved, but with a new sense of responsibility, it will be to his advantage if he realises he has only escaped from one maze to enter another, one more spacious, perhaps, but none the less puzzling, and it is a maze likely to last him all his life if that be passed in the practice of his profession. Yet before he enters it I think it would be well if he were conducted into an annexe to the original maze with the words "History of Medicine" placed above it, an annexe where he might profitably spend a little time in study and from which he would come a wiser and more humble man, able and willing to subscribe to the words of England's last great Poet Laureate:—

> "Yet I doubt not through the ages one increasing purpose runs
> And the thoughts of men are widened with the process of the suns."

THE PREVENTIVE IDEA AND ITS APPLICATIONS.

You will remember how, in the second place, it was proposed to discuss how Sir George Newman's idea of permeating the medical curriculum with the preventive idea could best be carried into effect. In the short time at my disposal I can, of course, merely touch lightly on the subject which is one of considerable complexity and difficulty. Newman's plea has found support both in Great Britain and the United States, but, in one respect, the younger country has gone further than the older, for, in the person of Prof. W. S. Leathers, the Vanderbilt University, Nashville, Tennessee, aided by a grant from the Rockefeller Foundation, has appointed someone charged with the duty of superintending the permeation. I had an opportunity of talking things over with Prof. Leathers when he was in London, and it was clear that all would not be plain sailing. The medical student of to-day has so much both to ingest and to digest that it is very easy to overload the curriculum and precipitate a crisis. Again, in some instances we have to do with "blind leaders of the blind." The teachers themselves are not fully versed in preventive principles. How Prof. Leathers has faced his problem I do not know. I only wish he were here to tell us. I think the difficulty of inculcating the preventive idea is easier at the beginning of the

medical course than during its later stages. In this part of the maze one can see here and there strands of another guide-rope than that marked biological. In other words, at present, in subjects like physics, chemistry, and zoology the instructors draw some of their examples from matters closely concerned with the public health. Many of the principles they enunciate play a part in preventive medicine, and sometimes all that may be required is to lay stress upon them from the standpoint of the hygienist, remembering that under the title hygenist the student and exponent of sociology and eugenics is included. The teacher of physics can easily direct the student's mind along preventive grooves, or, to keep to our original simile, see that he grasps the new guide-rope in the maze. When he teaches the use of meteorological instruments he can discourse on the prophylactic uses of climate, when he expounds certain laws of humidity and air movement he can remind his hearers of what adequate ventilation means to health, especially, perhaps, in certain industries, when he touches upon hydraulics he can find useful illustrations from engineering practice in water-supply and sewage disposal. During the study of electricity he may cite the effects of electrical disturbance upon white men in the tropics, and the beneficial effect of thunderstorms. Under dynamics he can consider the human body as a machine and show how certain exercises will ward off certain deformities. These are but a few suggestions. It is evident that they can be multiplied but never *ad nauseam*, for any sound argument which will impress upon the student thus early the value of prevention of disease is to the good, and, in any case, it is likely to make his physics more attractive and his study of public health easier when he comes to it.

Chemistry, both inorganic and organic, offers a good opportunity to the apostle of preventive medicine. Take the dangerous trades and the use of poisonous substances in various kinds of industries. A disquisition on the prevention of lead poisoning can be made full of interest and at the same time furnish chemical instruction of value. A subject like your tetra-ethyl-lead problem in the States might be turned into a useful lesson. Excellent prophylactic ideas can, as they say in the States, be "sold" the student during a consideration of the chemistry of air and water. The mercurials and organic arsenicals can be made to furnish a sermon on the prevention of venereal disease, though, perhaps, this is dangerous ground over which to lead a student in his first year of medicine. Yet if the lay public are instructed, why not the youthful disciple of Æsculapius? The chemistry of carbon conjures up coal and smoke, and at once smoke-prevention and all the lessons to be learned from it give zest and life to the lecture. These are very obvious directions, probably to some extent exploited at present, but there are other avenues. What of the lime salts and questions of dental hygiene and the warding off of rickets? What of preservatives in food? What of nitrogen in sewage sludge? What of chemical substances, like Schweinfurth's green and "stoxal," used in the destruction of insect vectors of disease? It is, of course, inexpedient to give lengthy disquisitions on these subjects. They should be used as an electric torch is used to illuminate and to show what lies ahead. It is like the art of the impressionist, but, if properly practised, it should not fail of its effect.

In zoology it is easy to find themes, but in a more indirect way, perhaps, that is to say by a careful selection of types during the study of which reference can be made to their importance in medical work and indications given of how their ill-effects can be obviated. As examples take under the protozoa, the amœbæ; under the insects, the mosquito; under the helminths, the hookworm. As a matter of fact, there is at Edinburgh University, for the third-year student, a special short course in medical entomology and parasitology, which affords abundant scope for talking about prevention. But in zoology there are other ways of spreading the gospel of prevention. The rabbit is one of the types always in evidence, and there can be no harm in telling the student about the discovery of tularæmia, and how its spread may possibly be checked. His interest in the rodent is likely to be quickened thereby. Similarly, if he dissects a mollusc like a mussel or a snail, he should be told, on the one hand, how edible shell-fish may spread disease and how they can be safeguarded, and on the other he may learn the important rôle of certain water snails in some helminthic maladies, and how snails can be slain with copper sulphate, if indeed he has not already learned this fact during his chemical studies.

At this early stage the thing must be carefully done, or the student will be crammed with ill-digested facts, and will become the prey of that half-knowledge which is so dangerous. As a forgotten poet once said:—

"Be ignorance thy choice where knowledge leads to woe."

Botany does not lend itself so fully to the illustration of the preventive idea, but lessons can be drawn from it, even apart from those suggested by the bacteria which, indeed, are better left until pathology is tackled. So far as tropical hygiene is concerned, botanical knowledge has its uses. There is the question of the flora associated with the prevalence of the tsetse-fly, there is the planting of eucalyptus and sunflower to dry swampy ground, there is the rôle of the Bromelias and other epiphytes as mosquito nurseries, there is the question of mosquitoes breeding in the tops of coconut palms and the action of azolla, lemna, bladder-wort, and other aquatic plants on culicine life and activity. The hygienic uses of certain grasses can be discussed along with the Graminaceæ, reference may be made to the old practice in India of clearing water with the fruits of *Strychnos potatorum*, the value of the water chestnut in averting famine may be cited. The edible fungi will suggest the measures to be taken to avoid the poisonous and inedible, while the transpiration and respiration of plants and the shade properties of certain trees may bring up the subject of aboriculture in towns. Again, is there not the question of the traveller's palm and the baobab with their reservoirs of drinking-water, the barrel cactus of Mexico, and the wonderful Narra fruit of Damaraland which saves the Hottentot there from extinction.

Anatomy can easily be turned into a quarry from which ideas on preventive medicine can be delved and shaped. There is the question of posture and all that it implies. Once again the lime salts come to the fore, and with them and also apart from them the hygiene of dentition. The skin makes a good text, both as regards Besredka's new ideas on immunity and with reference to light and pigment, while chest expansion, the prevention of fibrositis and other forms of rheumatism, the prophylactic value of certain forms of exercise upon muscles, the guarding against eyestrain, and hundreds of other questions hinge upon anatomy.

What is true of anatomy is, of course, even more true of physiology. There is the whole vast subject of industrial hygiene in which physiology plays a prominent, indeed a pre-eminent, part, and to which the student's attention may from time to time be directed with advantage; there are the physiological problems associated with the hygiene of infancy, childhood, puberty, and adolescence. The preventive rôle of hormones, the functions of vitamins, especially in warding off the deficiency diseases, the question of protecting the heart, lungs, and kidneys from strain, all merit attention. Then there are preventive lessons to be drawn from the study of the higher functions and of the special organs of sense. And so on; it would take much too long a time even to mention all the possibilities, but I cannot help thinking that, despite the wealth of examples, it may perhaps prove more difficult to permeate the physiology course with the preventive idea than any other branch of study, and this largely because the

average physiologist is so immersed in the fascination of his subject that he is apt to regard it as the acme of existence, not as a means to an end. Moreover, the type of mind which takes to physiology is rarely that which is attracted by the wider issues of public health, though there are notable exceptions. If, however, the physiologist will look upon his subject, as, in some measure, a combination of the Institutes of Medicine with the Institutes of Hygiene he will have unrivalled opportunities for reminding his class that there is a Latin maxim which says *Qui non prohibet quod prohibere potest, assentire videtur.* "He who does not prevent what he has power to prevent, is regarded as assenting to it."

THE CLUES.

From this part of the maze onwards it is easy to place the new guide-rope in position. The study of bacteriology teaches many lessons in prevention on which we need not dilate. Is not immunity and all it predicates the very essence of prophylaxis? During his pathology studies the student can be led to see, not only how important it is to prevent disease altogether, but to grapple with it at the outset. The history of cancer may be adduced to point the moral. Again, the study of intra-uterine pathology will pave the way for further conceptions later in the curriculum, while he can also be made to see in many instances how the pathological processes of old age may be held in abeyance. Preventive measures in the case of comparative pathology may be cited to good effect, considering that so many parasites and diseases of animals are transmissible to man. Once more the hygiene of industry comes into the picture and, indeed, on every side lie lessons ready for use.

No longer can anyone say that materia medica and therapeutics are the handmaidens of curative medicine alone. They have now a much wider application. Indeed, pharmacology nowadays is as much concerned with the prevention as with the cure of disease. We know that the administration of certain drugs can and does prevent the development of a malady, the virus of which has been implanted in the human body. We know that timely exposure to sun and fresh air is a protective measure of great importance. Psychotherapy is best employed as a form of mental hygiene, while vaccines and sera are, generally speaking, more valuable as prophylactic than as curative agents.

What better example of preventive medicine can there be than the Pasteur method for rabies and its recent application to the dog?

Sanitas sanitatis, omnia sanitas, we see how the slogan can and should sound through the whole maze of medicine. As the student passes to his clinical studies it will become intensified, and, to change the metaphor, he will grasp the new guide-rope with a firmer grip, though still clinging on one side to his biological leading strings.

This address would double in length were I to consider all the ways in which the preventive idea may permeate general medicine, surgery, midwifery, gynæcology, pediatrics, diseases of the skin, and of the other special sense organs, mental diseases and even anæsthetics, for is there not a technique to prevent chloroform poisoning? Much of Sir George Newman's pregnant suggestion has yet to be worked out in detail. Its application will not be simple. It will call for patience and perseverance. I am very conscious of the fact that I have not been able to deal with it in the way it demands. Yet I hope that, at least, I have succeeded in showing in the first place how arduous, yet how engrossing, is the progress through the maze of medicine, and in the second place how, here in the University of Rochester, as elsewhere, it were well to reinforce the biological guide-rope in that maze by one leading step by step, yet ever more directly, to that conception of the prevention of disease which is becoming, if it has not already become, the lodestar of the physician, the hygienist, and the research worker alike. When once this doctrine is established, and not till then, it will be possible to assert that we are doing our best to preach and put into practice a belief founded on that wise saying of ancient Greece, where long ago certain basic principles were clearly recognised:—

"Without health life is not life, life is lifeless.'

An Address

[ABRIDGED]

ON A

HALF-CENTURY'S PROGRESS IN OPHTHALMOLOGY.

Being the Presidential Address delivered to the Section of Ophthalmology of the Royal Society of Medicine on Oct. 8th, 1926,

BY ERNEST CLARKE, C.V.O., F.R.C.S. ENG.,
CONSULTING SURGEON, CENTRAL LONDON OPHTHALMIC HOSPITAL.

[Mr. Ernest Clarke began with a warm testimonial to the learning and merits as a teacher of Mr. Waren Tay at Moorfields, and then passed in rapid review the influence on ophthalmic surgery produced by the introduction of antiseptics and of local anæsthetics, pointing out the danger of the latter which in allaying pain might mask the symptom most disturbing to the subject so that the cause of the trouble is not inquired into. He proceeded to speak on:—]

EYESTRAIN AND CYCLOPLEGIA.

Eyestrain had been recognised and was styled "asthenopia" and practically the only symptom allocated to it was headache. In 1892 I published a book on "Eyestrain," which was very well received and reviewed. I was inspired to write it by the work of Gould, of Philadelphia, and I shall ever be most grateful for undertaking this work as it entailed reading every published book on refraction, and Donder's "Classical Treatise" became my daily companion. Gradually eyestrain has been taking a more prominent place in ophthalmology and general medicine. We now know that there is probably no functional nerve trouble that may not be caused or partly caused by eyestrain; that it enters as a second or third partner in innumerable complaints, and that by preventing it we may indefinitely postpone epileptoid attacks, migraine, recurrent iritis, and possibly delay or postpone the appearance of glaucoma and cataract. We know that eyestrain is more likely to be present with small errors and that in sensitive patients 1/8 D. may make all the difference between happiness and content, or discomfort and unfitness. In certain individuals eyestrain may be one of the frictions of life, and a waste of nerve energy; just as friction is a waste in mechanics. . . . This wasting is very often small, but it is going on during all the waking hours when eyestrain is present and may be imperceptible—that is, no definite symptoms such as headache may indicate its presence, hence it is most insidious. This waste lowers the resisting power to disease both locally and generally, so that the individual exposed to some infection which he ought to be able to withstand succumbs because his fighting power has been lessened. As in these days preventive medicine holds a very high place, the possibility of the presence of eyestrain should always be borne in mind.

There are some who are preaching that cycloplegics are not necessary in estimating the refraction of the eye, but speaking to you with the experience of a life's work I would warn you not to listen to them. Most people under 40 years of age and some under 50 do not, and cannot, relax their accommodation completely so that you cannot get down to the "bed rock" of the real condition of the eye. Donders

preached the value of paralysing the accommodation, and 70 years has only served to strengthen his teaching. It is true that in many cases the atropine or homatropine examination reveals nothing new and the cycloplegic need not have been used, but in my experience these cases certainly do not amount to 25 per cent., and for the sake of the remaining 75 per cent. we must paralyse the accommodation in all young patients. It is, however, important to remember that unfortunately we have a dilated pupil during our examination, and therefore a post-cycloplegic examination is very often necessary before prescribing glasses.

In the discussion on a paper before the Ophthalmological Convention last year by Mr. Burdon Cooper,[1] a good deal was said about the abuse of cycloplegics, but Dr. Hawley, of Chicago, struck the right note when he said the object of the cycloplegic was not so much to find out the amount of hypermetropia or myopia, but the exact amount of the astigmatism, and there is no doubt that very small errors of astigmatism, that mean so much, cannot be fully revealed without a cycloplegic in patients up to 40 or 45. The ophthalmometer may reveal the presence of the defect, but in checking this with the subjective test, which should always be done, you can get no definite answer until the ciliary muscle is paralysed.

MYOPIA AND PRESBYOPIA.

In the treatment of myopia we certainly have advanced. In my young days it was customary to let myopes of, say, 3 or 4 D., do all their near work without glasses, and if the myopia was higher, for instance, 7 or 8 D., 2 or 3 D. was taken off for near work. Time has shown that the ideal treatment of myopia is to correct it fully with any astigmatism that is present, and force the ciliary muscle to do its proper work, and in this manner stay the progress. In the paper [2] I read before the Congress last year, I think I showed conclusively that Sir Arthur Keith was right—that myopia was due to a badly constructed sclerotic and that this was prenatal and inherited. I suggested that this faulty sclerotic might owe its origin to some defective influence of one or more of the endocrine glands. I pointed out that we might stay the tendency to lengthening of the eyeball or retard it by careful refraction, and by preventing undue convergence in the very early years of life.

Presbyopia used to be very inadequately treated—a plus glass generally the same in both eyes and no correction of astigmatism unless large in amount. Now we know that the presbyopic age is just the age when, if eyestrain is present, it does the most harm. The vital energy is less—recuperative powers are less, very often worries and troubles of life are more acutely felt. We must correct the distant vision if an error exists as well as the reading, and the best way of doing this is by making the patient wear bifocal glasses. The improvement in the optician's art has made the way much easier, for the invisible bifocals are a very great improvement on the old-fashioned so-called "Franklin glasses." The reason that many people dislike these bifocals is, I think, due to the lower or reading portion being often made too strong. I find from experience that at no time of life is an addition of more than 2·75 D. needed, and very often up to 65, 2 D. is sufficient to add to the top or distance correction. We must remember these bifocals are for constant use, and if the reading section is too strong objects slightly further removed from the eye, as food on the plate at meals, become blurred. Everything also depends on the correct centering of these glasses and also making sure that the division between the glass should not be higher than the margin of the lower lid.

For many years I have been recording the accommodation power of my patients, and these records now number over 6000. You may remember that I have found that the average accommodation power, age for age, is somewhat higher than Donders put it, that it is a very delicate index of the "physiological age" of the individual, that if a person looks older and is really older than his or her years, their accommodation power is lower than normal and vice versa; that toxæmia lowers it; and the removal of the toxic condition is followed by increased power.

[Here Mr. Clarke enumerated, as proofs of progress, the great changes which have taken place in the treatment of imbalance of the extra-ocular muscles, the additions to methods of diagnosis, and treatment due to X rays, radium emanations, ultra-violet light, and vaccine therapy, as well as to much bacteriological research. He proceeded:—]

RETINAL HÆMORRHAGE.

It is not so very long ago that hæmorrhages in the retina were all labelled *hæmorrhagic retinitis*. As high blood pressure was generally associated with their presence it was supposed to be the cause and bleeding was, in many cases, adopted as part of the treatment. Fortunately for the patient the effect of bleeding was very transitory.

We owe much of our new knowledge on the subject to Mr. Foster Moore. Dr. Dale and Prof. Krogh, of Copenhagen, have also supplied important material. We now know that high blood pressure in the brachial artery does not necessarily mean high blood pressure in the retinal artery; at all events, high blood pressure is as much a symptom as the hæmorrhage and they both indicate a toxic condition of the blood. Dale, in a recent paper, pointed out that Krogh has shown (and other physiologists have acknowledged the correctness of his investigation) that the capillaries have a contractile force of their own under nerve and hormonal control, and that with increased relaxation they become increasingly permeable to the constituents of the blood plasma until, when fully relaxed, they fail altogether to retain it, and the blood passes without hindrance into the surrounding tissue. If hæmorrhage (from its derivation) means a bursting of blood it is not the proper term to use for this condition; one dislikes hybrid words, but *hæmoflux* would be a more appropriate term. Such a hæmoflux would be a very different thing from a large subhyaloid hæmorrhage, or what Mr. Fisher has rightly suggested should be called a semilunar retinal hæmorrhage, from a ruptured blood-vessel. It has been said that a proper classification of retinal hæmorrhages is badly wanted. Foster Moore has recently suggested the following, which seems to me very adequate. He says the leakage of blood occurs: (1) From arterioles from lodgment of infected emboli. (2) From capillaries due to toxins or to the impairment of the nutrition of the endothelium as in anæmias. (3) From the venules from mechanical causes. If the toxins are removed the blood-vessels will be restored to the processes of filtration, diffusion, and osmosis. The blood patches will be gradually absorbed, and if the external limiting membrane has not been penetrated the retina will gradually resume its normal appearance. I recently had a case of a lady, aged 49, whose right fundus was covered all over by superficial blood patches. She was found by Dr. McCrea and Dr. Carnegie Dixon to be toxic from streptococcal and *B. coli* infection. She received a series of doses of autogenous vaccines and in a few months completely recovered with normal vision, and not the semblance of a scar is now visible in the retina. We must remember that the leakage of blood in the retina due to toxæmia may be non-bacterial in origin, as Mr. Fisher pointed out in a very valuable paper on Retinitis in Pregnancy read before this Section some ten years ago.[3]

[Mr. Clarke next noted the connexion of dental sepsis with eye troubles, which is now so widely recognised, as is the influence of congenital malformations and their accompanying pathological changes.]

GLAUCOMA.

In the treatment of glaucoma, to take the place of the sacrifice of a piece of iris, a filtration cicatrix has been substituted. De Wecker, who made the suggestion first, was followed by Lagrange, Elliot,

Herbert, Von Hippel, and many others. From Mr. Davenport's paper on 405 trephine operations at Moorfields for four years in the September number of the *British Journal of Ophthalmology*,[4] Elliot's trephine operation appears to be the most popular for simple chronic glaucoma, and I personally quite agree with this, while iridectomy, introduced by Von Graefe 70 years ago, still holds its own for congestive and acute glaucoma.

The pathology of glaucoma has been taught us in the past by such masters as Priestly Smith and Treacher Collins. Lately, Thomson Henderson has advanced a new theory; that the access of the aqueous to the canal of Schlemm is prevented by sclerosis of the ligamentum pectinatum, as a predisposing cause, coupled with an immediate exciting cause which is vascular. Colonel Herbert has advanced another new theory that chronic simple glaucoma arises mainly, if not entirely, from a defective inward pull upon the pectinate ligament. . . .

[He attributed modern improvements in the treatment of convergent strabismus largely to the enlightenment of parents who bring their children now at an earlier age so that a considerable proportion can be cured by glasses alone. He spoke warmly of the ophthalmic work produced by war conditions, and especially of the preventive labours of Sir William Lister and others in respect of trachoma "hitherto the scourge of armies," and continued :—]

The Career of the Ophthalmologist.

Another great advance that has taken place has been in the education of the intending oculist. In the early days the only eye work was surgical and when the various hospitals established eye departments one of the surgeons on the staff was selected as head of that department. Naturally, the younger men who aimed at specialising in eye work concentrated on surgery and took the Fellowship of the Royal College of Surgeons, the study for which occupied all their time to the exclusion of any deep knowledge of medicine; consequently the proportion of oculists without a special medical degree at this time was *4 to 1*. As the knowledge of ophthalmology increased it became apparent that medicine was as important or even more important than surgery, so that now almost all the younger oculists possess a medical degree and the proportion is reversed. A few years ago Mr. Rayner Batten read a paper [5] before this Section hinting that the time might come when some conscious of not being good at surgery would concentrate on the medical side and call themselves medical ophthalmologists with the prefix of "Dr." which (in London) is not considered to be our correct designation. One great advance in our education has been the recent establishment of diplomas in ophthalmology and the possibility of taking the F.R.C.S., and M.S., of London with ophthalmology. I would, personally speaking from my own experience, strongly urge those who have just qualified and have started serving their apprenticeship as clinical assistants at one of our eye hospitals, to spend at least a year in general practice if they can possibly manage it. The value of this experience is priceless. It will teach them first that the eye is a very intimate part of the body and not a solitary organ; it will teach them how to drop their hospital manners and how to deal with private patients; it will teach them what they are never taught, or certainly in my day were never taught, how to deal with their colleagues and to realise that what is called medical etiquette is nothing more than acting according to the principles of common politeness and doing to others as you would be done by.

Although we cannot point to any great changes in surgical instruments during this long period, our equipment has enormously improved. Whereas the reflecting ophthalmoscope requires a distinct education to enable it to be used efficiently, the electric ophthalmoscope has considerably lessened the difficulties and put into the hands of every medical man the means of viewing the fundus. At first this may prove a mixed blessing but eventually it must be for good. A very great advantage of this instrument is the possibility of examining a patient in any position. On account of being able to approach so near the eye with the instrument, we can get a more extensive view of the fundus through a smaller pupil and a darkened room is not a sine qua non. In association with the ophthalmoscope I must allude to the increased facility for recording pictures of the fundus which has been instituted by Messrs. Hamblin at the suggestion and under the supervision of Mr. Rayner Batten. Such recording will enable us to study different phases of a disease in the same subject at different times and also the same disease in different subjects, and under different treatment, and these collective records will be most valuable for educational purposes.

The latest Meyrowitz's model of the ophthalmometer originally given us by Javal and Schiotz is a great improvement on the old Kagenaar model, and I strongly urge its more extended use, for if used intelligently as a servant, and not as a master, it is a most valuable instrument, saving time in refraction work and giving an accuracy (especially in the estimation of small degrees) that no other method can rival.

Lastly, during the last few years, Dr. Gulstrand has introduced us to the slit lamp. This instrument is surely going to help us in thoroughly appreciating structures and changes in the anterior part of the eye as the ophthalmoscope has done in the posterior region. As it has taken years for us to become acquainted with the latter, so will it probably be years before the slit lamp has yielded us all the knowledge we hope to obtain from it.

[Mr. Clarke concluded by pointing to the recent labours of Mr. Leslie Paton, Sir John Parsons, and Dr. Gordon Holmes on the neurological side of ophthalmology; to the work of Dr. Duke-Elder on ocular circulation; to that of Mr. Fisher and Dr. de Schweinitz in connexion with the pituitary gland, and concluded :—]

We have a grand stimulus to help in this progress when we realise what our work is. Treacher Collins, in his Bowman lecture, Elliot Smith and Sir Arthur Keith have shown us that the development of the area in the brain associated with vision has proceeded pari passu with the development of our physical and spiritual state. We can manage without taste, smell, and even hearing, but with blindness we lose our independence, and in the whole of medicine no part, it seems to me, is so overwhelmingly important as ophthalmology. This consideration should make us always put in good work which at the day's end, or our life's end, will always leave a satisfactory feeling of "something attempted, something done."

Royal Medical Benevolent Fund.—The following are some additional cases relieved at the last meeting:—

Widow, aged 73, of L.R.C.P. Edin. who practised in the south of England and died in 1920. Eldest son, aged 45, allowed his mother £20 a month, but this ceased on his death in January last. Second son not in a position to make regular allowance but helps to the best of his ability. No other income. Voted £36 in 12 monthly instalments.

Widow, aged 54, of M.R.C.S. who practised in Wales and died in 1924. Owing to ill-health quite unable to work. Lives rent free in a cottage and receives the rent 5*s*. a week of an adjacent one. No other means but receives poor relief. Voted £26 in 12 monthly instalments.

Widow, aged 55, of L.R.C.P. who practised in London and died early this year. Late husband was in receipt of an Epsom Pension, the Old Age Pension, and an annuity from the Fund, all of which ceased at his death. Applicant is now looking out for work to maintain herself. The Fund voted £17 since May, and £18 in 12 monthly instalments from Nov. 1st next.

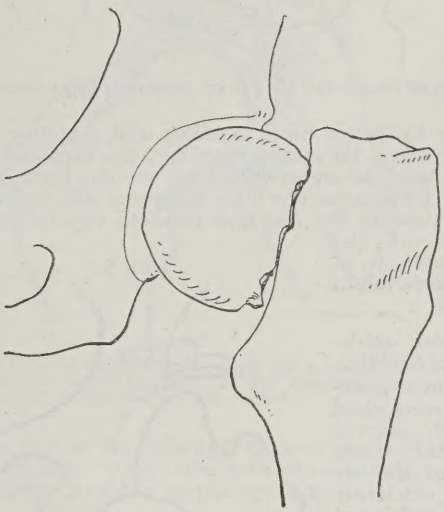
Subscriptions may be sent to the Honorary Treasurer, Sir Charters Symonds, K.B.E., at 11, Chandos-street, Cavendish-square, W. 1.

SOME CONTRIBUTIONS TO THE RECONSTRUCTIVE SURGERY OF THE HIP.*

BY ERNEST W. HEY GROVES, M.S. LOND., F.R.C.S. ENG.,
PROFESSOR OF SURGERY AT THE UNIVERSITY OF BRISTOL.

THE hip-joint, the largest and most important in the body, presents special difficulties and special displacements. It is more liable to serious disease and congenital dislocation than any other joint. Possibly this may be due in part to the evolutionary change from the quadruped to the biped gait and progression.

FIG. 1.

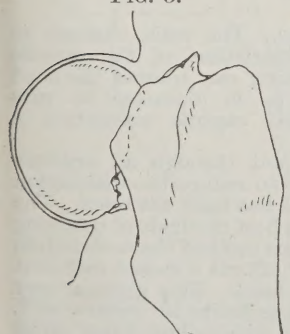


Outline of skiagram of fractured neck of the femur in a man, aged 35, before operation.

Fracture of the Neck of the Femur.

Fractures of the true neck of the femur—that is, of the bone proximal to the intertrochanteric line—present very special features. Unless impacted, these fractures never undergo natural union, and yet if artificial impaction is brought about bony union will occur just as certainly as in any fracture elsewhere. Non-union, which is the natural event in these cases, is due to four causes—namely, want of apposition, poor blood-supply, interposed capsule, and the action of the synovial fluid. Of these, the first two are by far the most important. If efficient treatment is delayed for more than a few weeks marked atrophy occurs in the proximal fragment, and after such an event, perfect restitution either of form or function is impossible. The three essential points in the treatment are: early intervention, accurate apposition, and firm fixation. If these points are observed, firm bony union can be secured in practically all cases whether in old or young.

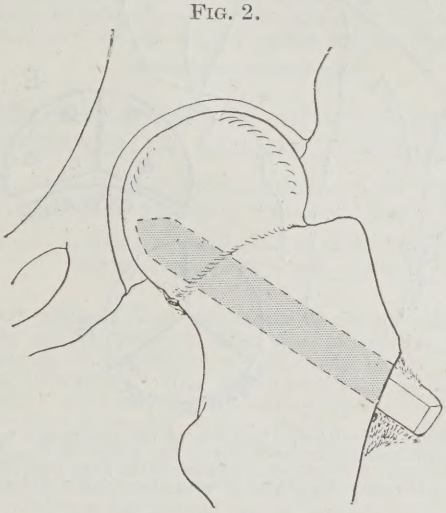
FIG. 3.



Outline of skiagram. Woman, aged 68, before operation.

The method advocated by Whitman is a great advance on previous methods of treatment. Under an anæsthetic the leg is pulled downwards, inverted, and abducted, thus impacting the fracture. The abducted limb is fixed in a plaster spica for three to six months. The objections to this method consist in its uncertainty and the very great torture and tedium of keeping an adult in a plaster case for several months. The uncertain result is due to the facts that manipulation of the leg cannot correct a misplaced proximal fragment, or get rid of that portion of the capsule which may lie between the broken surfaces.

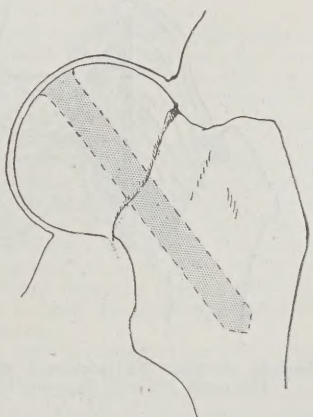
FIG. 2.



The same three months after pegging operation.

Fixing the fracture by means of a bone peg (Figs. 1 and 2) gives a much more certain and perfect union with less strain upon the patience and fortitude of the patient. The joint is exposed by an anterior incision, the capsule opened, the fractured surfaces laid bare, the fracture accurately replaced by manipulation, and a square peg 4½ in. long, ⅜ in. thick, driven from the base of the great trochanter through the neck into the head. The limb is put up in moderate flexion and abduction, steadied by slight traction. In six weeks' time the patient can walk with a caliper, and in three to six months can resume a normal life.

FIG. 4.



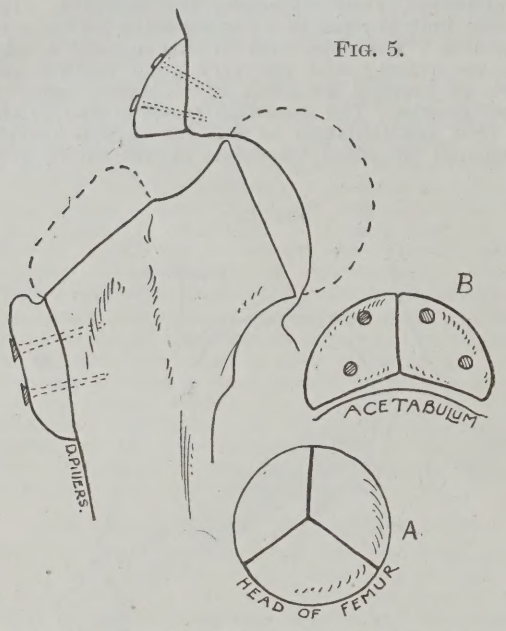
The same after operation. Note that in this case the peg has been driven in from above downwards.

Special modifications of the pegging operation are useful under certain circumstances. The peg may be inserted from above (Figs. 3 and 4). This is useful when the proximal fragment is very small and the line of fracture difficult to expose outside the hip socket. The head of the bone is dislocated and nailed on to the neck, after which the bone is replaced in position.

* Abstract of the Bradshaw lecture, delivered before the Royal College of Surgeons of England on Nov. 11th. The full text will appear in the January number of the British Journal of Surgery.

In old cases, where the fracture is of long standing, it may be useful to employ a living bone peg taken preferably from the fibula, because this type of peg will substitute some new bone in place of that lost

FIG. 5.



Reconstructive operation. The top of the trochanter is fixed lower on the shaft, the acetabulum has a new rim made from the old head. A = method of division of the head; B = method of fixing the shaped portions of head above the acetabulum.

by atrophy. The peg may be inserted blindly—that is, without exposing the joint at all. This method should be reserved for patients whose age or debility makes it desirable to avoid the more serious operation. The drill hole into the neck and the insertion of the leg should be made under the guidance of the X rays. Conditions of slipped epiphysis should also be treated by pegging operation, which is capable of restoring the bone to its perfect original form.

FIG. 6.

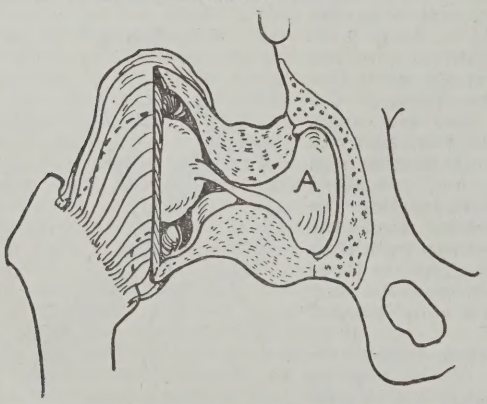


Diagram showing the thickened and constricted capsule as the main obstacle to reduction. A = acetabulum.

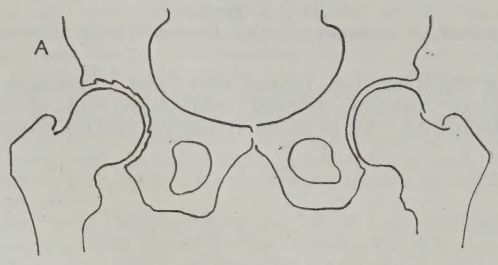
Ankylosis of the Hip.

There is no entirely satisfactory method of treating an ankylosed hip. It is comparatively easy to cure the patient of pain and to correct deformity, but it is extraordinarily difficult to secure mobility and stability at the same time, therefore, only those cases are operated upon in which double ankylosis of the hips or simultaneous ankylosis of the hip and knee make some treatment imperative. The more complicated methods of arthroplasty tend to leave the patient with a very stiff hip. It seems better, therefore, to be content with some modification of excision of the head of the femur. Two suggestions are made

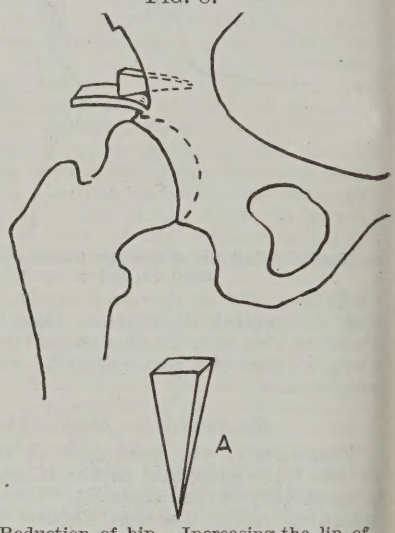
FIG. 7.



Reduction of congenital hip (A) by deepening the acetabulum.

in order to secure both mobility and stability after this excision. To attain mobility, the capsular ligament is used as an envelope for the cut neck of the femur. To prevent the bone becoming dislocated the excised head of the femur is cut into two fragments and affixed to the upper margin of the acetabulum (Fig. 5).

FIG. 8.



Reduction of hip. Increasing the lip of the acetabulum by a bone flap from the ilium. A = ivory peg for propping the flap.

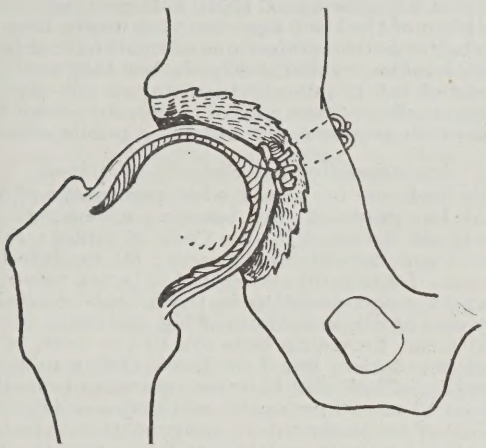
Congenital Dislocation of the Hip.

It is now generally recognised that early cases of congenital dislocation of the hip can be efficiently treated and cured by manipulation. But it is not realised that in older children when manipulative reduction is impossible, a great deal can still be done by open operation to get firm and useful hip-joints. It is worse than useless to use elaborate and difficult methods of manipulative reduction in these older cases. The main obstacle to reduction is the tight constriction of the capsule (Fig. 6). No force or cunning can compel the head of the femur measuring 1 in. in diameter to pass through a thick constricted capsule presenting a channel of about $\frac{1}{4}$ in.

Open exposure of the joint through an anterior incision makes it quite easy to reduce the dislocation after the constricted capsule has been slit open. The problem then arises as to the best methods of retaining the femur in its socket. In one method the acetabulum is deepened (Fig. 7), until it affords a socket sufficient to take the whole femoral head. This gives a very secure joint but one which is liable to become stiff. In another method, that which has been most frequently used, the cartilage of the acetabulum is left undisturbed and a new rim is added to the socket by turning down a part of the outer surface of the iliac bone (Fig. 8). In a third method the capsule is cut from its attachment to the pelvis and tied round the head of the femur, the acetabulum is gouged out, the head of the bone wrapped in the capsule is placed in the socket and anchored there by stitches which fix the capsule to the floor of the acetabulum (Fig. 9).

In the late or adult cases of congenital dislocation a great deal can be done to cure both the pain and the lameness by a subtrochanteric osteotomy, putting up the leg in full abduction. But this is only suitable for unilateral cases. When the dislocation is bilateral, the head of one femur can be brought down into the socket by removing about 2 in. of the shaft of the bone below the small trochanter. This will give

FIG. 9.



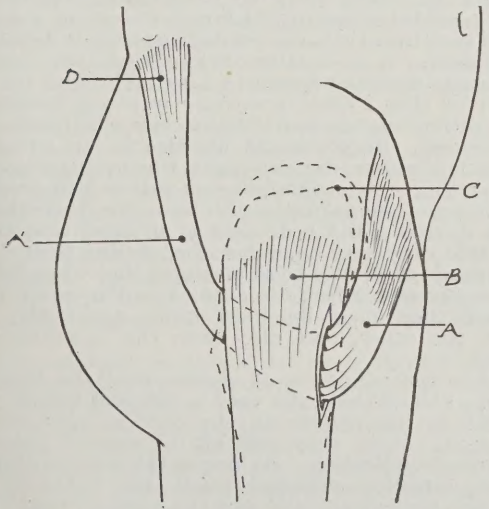
Third type of operation in which the acetabulum is deepened and the head enclosed in the capsule. The capsule is sutured to the floor of the socket.

a firm hip on one side and the two legs will be of the same length. At a later date, if necessary, an osteotomy may be done on the opposite side.

Infantile Paralysis Affecting the Hip Muscles.

Extensive infantile paralysis of the lower limb can to a large extent be made good by means of apparatus

FIG. 10.



New abductor muscle. A = tensor fasciæ femoris; A' = iliotibial band, brought through the trochanter and fixed to erector spinæ; B = outer surface of trochanter covered by origin of vastus externus; C = top of great trochanter; D = erector spinæ.

which fixes and controls the knee- and ankle-joints, but paralysis of the gluteal muscles leads to a complete inability to balance the trunk upon the leg and necessitates the permanent use of crutches. It has been suggested that the lost abductors may be replaced by using the tensor fasciæ femoris or the erector spinæ muscles. Neither of these muscles singly can make a very efficient abductor, partly because one lies in front and the other behind the required line of action, and in the case of the back muscle because of the difficulty in getting a necessary tendinous insertion. By combining these two muscles an efficient digastric abductor of the hip is formed. A long incision is made on the outer side of the thigh; the iliotibial band is isolated and cut above the knee; the fascial band forming the tendon of the tensor muscle is brought backwards through the base of the great trochanter; the erector spinæ muscle is exposed by a vertical incision and the lower portion isolated by cutting through its lower origin and splitting this part of the muscle upwards for about 4 in.; the iliotibial band is brought backwards and upwards through a tunnel under the skin and fixed to the isolated part of the erector spinæ muscle (Fig. 10).

THE MANAGEMENT OF INFECTIOUS DISEASES IN BOARDING-SCHOOLS.

Being a Presidential Address delivered before the Society of Medical Officers of Schools on Nov. 12th

BY A. I. SIMEY, M.D. CAMB., F.R.C.P. LOND.,
MEDICAL OFFICER TO RUGBY SCHOOL.

THIS address does not claim to be an exhaustive review of the rules dealing with infectious diseases in schools, a model for which exists in the Code of Rules published by this Association. Different schools, I am aware, differ somewhat in their regulations—for example, some regard the incubation period of mumps as extending to 28 days, whilst others put it down as 26, or even less—but I take it that the Code represents fairly well the principles on which our regulations are based, and my remarks will deal more or less with what you may see recommended there. My aim is merely to open the question and provoke discussion, for I believe that some of you have a desire to see the Code modified or amplified in various details in accordance with the trend of modern thought and requirements.

It will be helpful to approach the subject from two main aspects: (1) The means taken to prevent the introduction of infectious disease into boarding schools. (2) The disposal of patients suffering from infectious ailments at school and the best methods of preventing the spread of infection, when it has once manifested itself.

Quarantine and Disinfection.

It is occasionally urged against the authorities of boarding-schools that whilst they insist on strict rules as to notification and quarantine for boys exposed to infection at home, they do not do unto the parents as they insist that the parents shall do unto them, in two respects: (*a*) Sometimes they are not punctilious enough in notifying parents that their sons have been exposed to infection at school, or that such notification is not as helpful as it might be to enable them to make arrangements for quarantine at home. (*b*) Whereas the school authorities refuse to allow a boy to return to school within the quarantine period, they do not hesitate to send him home directly term ends, even though it is likely that he will develop the infection soon after his arrival home.

The answers to these two criticisms are: (*a*) That great care should be taken that the school authorities formally notify parents *as early as possible* before the dispersal of the school for holidays, giving as much information as may be reasonably expected to enable the parents to make suitable arrangements for quarantine. (*b*) That it is not reasonable to keep a boy back at the end of a term to prevent his illness occurring at home; for, if a boy *has* to be ill, home is the more appropriate place for him. I hardly think it necessary to go further and point out that it is essential that the school premises be empty during holidays for cleansing and ventilation after a term of epidemic illness.

Critics should also recognise that it is a much more serious matter to introduce infection into a big school of pupils living in common day and sleeping quarters than it is to introduce it into a private house where, in addition to ampler accommodation, the susceptible individuals are fewer and more easily isolated from one another.

If it is agreed, to begin with, that every precaution must be taken to keep infection out of our schools, then I do not think that the usually accepted rules of quarantine in cases of exposure to infection during the holidays can be made much less stringent; on the contrary, I think that even more stringent rules should be laid down about common catarrhal affections, and that, at present, a special certificate should be required to the effect that, after due inspection, there is no sign of certain skin affections such as tinea cruris, impetiginous spots, and boils. But I do not think that it is necessary to insist on the full quarantine period "dating from the day of disinfection," except in the cases of diphtheria and scarlet fever. Even in these diseases I doubt the efficacy of disinfection of clothes, except by steam, but it gives some people a sense of security. To my mind, it is the condition of the nasopharynx, and not the clothes, that matters; externally situated, the virus of most exanthems dies down soon after leaving the body of the host, and rarely recovers, unless reinstated under optimum conditions, such as seldom, or never, occur normally.

There is, however, one point on which I should like to see agreement—viz., that inasmuch as a second attack of the scheduled exanthems is very rare, a pupil who, during the holidays, has been exposed to a given infection, provided that he himself has at some time in his life suffered from a well-marked attack from this infection, should be allowed to return to school without any delay, and, except in the case of diphtheria and scarlet fever, without disinfection of his clothes.

I believe there is very little danger from the clothes of persons exposed to infection, and that infectious diseases are rarely spread by the clothes of contacts. How rarely do we see them transmitted by medical attendants. Exceptions to this rule are, perhaps, diphtheria, scarlet fever, and chicken-pox. To sterilise clothes, disinfection by steam is the most, if not the only, certainly efficacious means, and should be adopted in the case of the two former infections. Chicken-pox is so mild a disease, and may have so long an incubation period, and spreads so much less readily than most other infections, that, in my opinion, it should be removed from the list of scheduled infections in our boarding-school regulations. I would likewise remove rubella, were it not that there is sometimes considerable difficulty in its diagnosis from measles and scarlet fever, and that it is a most rapidly spreading infection.

Unfavourable Results of Prevention.

It is an unfortunate result of the present precautions taken to prevent the introduction of infectious disease into boarding-schools that a great number of boys pass through private schools without having contracted, say, for example, measles. In the public schools similar precautions keep the disease out for two, three, four, or more years until a very small proportion of the community is protected by a previous attack. Then, when finally infection creeps in, a really great and serious epidemic is started, each round of which is greater and more serious than the last, until a time comes when the rounds cannot be distinguished and, for want of sufficient accommodation, patients in early and later stages of illness have to be nursed together, the wards, perhaps, are so full that they cannot be cleared, ventilated, and cleaned, and complications arise, which turn an epidemic into a nightmare.

I sometimes wonder what would be the result of entirely abolishing our code of holiday quarantine precautions and allowing infection to enter schools more frequently, but in smaller outbreaks, spreading the incidence, so to speak, over a number of terms instead of crowding an unmanageable number of cases into a few terms at long intervals.

Personally, I believe it would make but little difference in public schools if we *did* abolish our precautions, so long as the preparatory schools continue to offer so impenetrable a barrier to the introduction of infectious diseases, and, no doubt, it is *their* best policy so to do; but regarding the interests of the scholars, it is better for them to have their infectious diseases apart from a large congregation of children of the same age—in other words, they had much better get their infectious ailments over at home. If they *must* have them at school, then they are better contracted before puberty than during puberty, and in the smaller community of a private school than in the much greater community of a public school.

Accommodation for Sickness at Schools.

This leads me on to ask what percentage of beds should be provided by boarding-schools, as this point is not discussed in our Code of Rules: (*a*) for surgical and non-infectious cases; (*b*) for infectious diseases. I am quite aware that it is not reasonable to expect accommodation in the school hospital for every case of illness in times of big epidemics, for this would mean providing beds for 40 per cent. of the school population, but I do think that a minimum percentage of beds should be recommended (something between 10 and 20 per cent.), and that a certain small number of these should be assigned to surgical and non-infectious cases, isolated, as far as possible, from those containing infectious cases, although, when an infectious epidemic has established itself in a school, there comes a time when almost every individual member of the community and every school premise has been exposed to the infection, which is ubiquitous.

This may seem to be somewhat of a digression, but in reality it is the link between the two main headings of my paper and an introduction to the consideration of the treatment and prevention of spread when once an infectious disease has manifested itself; for it is obvious that to attain this end, if indeed it is generally attainable, there must be a sufficient number of single-bedded rooms in which patients can be watched until such times as a case under suspicion is definitely diagnosed. It is equally obvious that there should be ample accommodation of a suitable kind for the sick; by that I mean good airy wards of a suitable size, with proper up-to-date lavatories, sick-rooms, and bathrooms. There should likewise be an adequate number of nurses, day and night, who must be capable of exerting a strict discipline as well as being skilled in their professional duties; for these, too, there should be a dayroom and bedrooms so situated that those on night duty may be undisturbed during their sleep. The wards must also be so arranged that when two or more separate infections occur simultaneously in a school they may be kept quite apart the one from the other, and also from the non-infectious wards.

As to the admission of visitors into the infected wards, I think that rules vary in different schools, but I find no instructions in our code on this knotty question. It is very difficult to suggest rules of universal application. So long as the number of cases of any infectious disease is small—i.e., in the case of the first patient affected and the second round—i.e., those infected by him—I think it wiser that no visitors should be admitted, although I believe that it is most improbable that they will carry infection on their clothes. Of course, boys should never be permitted to visit their friends whilst still infectious, but a housemaster or his representative, provided that he himself has suffered from the disease in question, should be allowed to pay a short visit once a day at such a time as is chosen as being most convenient by the matron of the sanatorium. It is important that her approval, or that of a nurse deputed by her, be asked before a visitor enters the ward. Whilst in the wards visitors should not sit

down, and should keep at a reasonable distance to avoid infection; their visits should be very brief.

Convalescence and Discharge.

Let us pass on now to approaching convalescence and the time of discharge.

I have already laid stress on the necessity for good bathing facilities. During convalescence each patient should be allowed one or two daily walks and at least one bath a day, special attention being given to the scalp. I believe that he may then be safely discharged, without further disinfection of his clothes or belongings (provided that books are not included in the latter class), except in the case of scarlet fever and diphtheria, when his clothes and bedding should be disinfected by steam and his other belongings (the weak point!) by antiseptics in aqueous or vaporised applications. The present regulations, according to which it is illegal for a patient convalescent after scarlet fever and diphtheria to walk out into the country, should be modified. The places or things that he is most likely to have infected are his dormitory, his various class-rooms, study, chapel, and other premises which he visited *whilst sickening for the disease*, and it is quite impossible to go round all the places he may have visited before his admission and disinfect them.

Fumigation by formalin vapour in such concentration as is usually adopted does little or nothing more than make a sanitary smell and make one feel a false sense of security. Fresh air, wind, and sunlight, when supplemented by the work of a good charwoman, are more efficacious, for soap is itself a good disinfectant.

And now comes the problem as to the day of discharge: our codes of rules err, I think, on the side of extreme caution. I feel that, as a rule, though by no means always, in mild uncomplicated cases a boy is safe to discharge when he is clinically fit to return to school. Thus, whereas in the case of scarlet fever a minimum of six weeks' isolation is usually demanded, there are not a few cases which are fit to discharge at the end of four weeks; the difficulty is to say which are those cases. It is well known that a certain few continue to be infectious, for no apparent reason, long after the usually observed six weeks are over, and I believe myself that the residual infection remains latent in the nasopharynx and may flare up again after a long interval if the convalescent develop a cold.

This suggests a possible precaution in having scarlet fever patients inoculated with an autogenous vaccine taken from the nasopharynx when convalescence begins. Concerning diphtheria I think our present rules, however exasperating they may be, *must* be retained in school work, even though the Klebs-Löffler bacillus, if it persist, be shown not to be virulent. In the case of measles I think a patient is never fit to return to school within 14 days of the full development of the rash, and often not till later.

I have already remarked on the difficulty which sometimes exists in diagnosing the rash of rubella from that of measles and scarlet fever and of other non-infectious conditions. But, once definitely diagnosed, I think that it should not necessitate detention of a patient who is physically fit to return to his work. Patients suffering from chicken-pox are nearly always detained too long, if the usual rules are followed. Given plenty of open air, soap, and hot baths, I believe they are safe when they are clinically and æsthetically fit, care being taken not to overlook the presence of glands.

I see no reason to alter the code rules as regards mumps and whooping-cough, for both of which infections I have more respect than the laity show them, though the actual period of infectivity in whooping-cough is probably short and limited to the catarrhal stages.

Laundry.

There is another practical point which deserves your attention.

The washing, especially handkerchiefs and sheets, of a boy who is admitted to the school sanatorium suffering from infectious disease needs special care. After his admission, linen scraps or the cheapest cotton handkerchiefs should be freely supplied in place of his own, and promptly burnt when soiled; but what about his underclothes and handkerchiefs with which he enters the wards, for they are the most likely to harbour the virus of the disease at its most infective phase. I feel most strongly that these should either be taken with him and washed at a sanatorium laundry, or else should be sent to a special laundry belonging to or set apart from the school, where special arrangements can be taken to keep them apart from non-infected clothes, and on no account should they be sent to private laundries which work for the general public. Indeed, I think that one of the possible sources of infection in a school may be the general laundry, and vice versa, infected school linen may possibly extend infection to the outside community.

Conclusion.

I have purposely refrained from any allusion to small-pox or to the routine use of the Schick and Dick tests in the management of diphtheria and scarlet fever in schools, as I have no personal experience of them as yet, and perhaps it is a little early to pronounce upon their practical utility in schools. In neither case have I yet known any outbreak of such dimensions that one might speak of it as an "epidemic," and I think that scarlet fever is the least infectious of the exanthems in boarding-schools. This is probably due to the fact that a comparatively large percentage of the community is immune to this disease.

To summarise, I feel that we have yet a great deal to learn about infection, especially as to its introduction into a community and its passage from one individual to another, and that too much stress is laid upon direct and indirect contact and too little notice is taken of spray and exhalations from the mouth and nasopharynx.

We are disposed, I think, to trust too much to artificial methods of disinfection, especially by chemical means, and to attack infection too little in its initial stages and too much when it is dying out naturally.

SOME OBSERVATIONS ON SOCIAL CAPACITY.

APPLICATION OF THE PORTEUS MAZE TESTS TO 100 BORSTAL LADS.

BY R. FITZROY JARRETT, F.R.F.P.S. GLASG.,
MEDICAL OFFICER, H.M. PRISON, CARDIFF.

THE ultimate problem facing those responsible for the future of the Borstal lad as his time for discharge draws near is well summarised by two questions appearing on the report to be furnished by the Institution, which pertinently inquire, "What the inmate desires to do on discharge," and "What he ought to do." Effectually to reconcile aspiration with capacity is a task of no small magnitude, and great care must be taken lest mere orderly and passive compliance with routine lead to false estimation of the lad's actual capacity to stand on his own, when removed from the atmosphere and guiding hand of the Institution. For the real test, in Tredgold's words, is "the test of life," and "the criterion of deficiency is not an intellectual but a social one."

It is a somewhat curious fact that whereas it is generally readily accepted that the physical weakling—e.g., with tuberculous diathesis or heart disease—cannot reasonably be expected to thrive unless placed permanently under favourable hygienic conditions, it is less common to encounter recognition of the need for a *permanently* "selected" environment to ensure

the safety of those whose weakness is evidenced, not in the physical, but in the mental constitution, by poorly developed social consciousness and low capacity for social adaptation. It is as though the lay mind were capable of grasping that an individual could be born so deficient in *physical* robustness as to mitigate against proper functioning as a social unit, but for some reason finds it difficult to conceive any human being as permanently lacking in the *mental* qualities necessary for effective existence in a modern social state unless, indeed, palpably mentally defective or insane.

Now it would certainly be a sufficiently difficult task to attempt to place all the nation's physical weaklings under perfect environmental conditions, but the problem is infinitely harder when the "weakness" to be combated takes the form of incapacity for adaptation to current social sanctions evidenced by repeated delinquency. Take the physical weakling from slums and mean streets and give him a chance and results are comparatively certain, but the "social" weakling may be placed with great care in circumstances in which 99 other citizens are making good, and when the day comes that his employer leaves a ten-shilling note on the office table for all to see, he alone of the hundred will take it, and most probably, in reply to your questions, he really will not quite know why he has done it. Talk to him long enough and you will no doubt succeed in suggesting to yourself that he took the money because his father was a drunkard or his mother was cross-eyed; because he was the eldest, middle, or youngest, of three and was actuated by some sort of complex; or because he did, or did not, go to the pictures; and you may persuade yourself that you have made an analytical study of the case, with the result that after the lapse of time you will find yourself in a position to prove that anything from collecting bird's eggs to wearing hobnail boots is "a cause of crime." And still, innumerable young people will go on collecting birds' eggs and wearing hobnail boots, perhaps, if they are very daring, even doing both these things at once, and they will never be seen in a police-court. For the truth is, as indicated by Burt, that the delinquent must be approached as a unique human being *with a peculiar constitution*. Because a faulty axle gives way, the chauffeur must not lay disproportionate stress on a few twists and turns and difficulties in the road. The primary fault is in the axle. "Every cause and every influence," says Burt, "no matter what its special form may be, is found to operate, and can only operate, through its inner psychological effects. Conduct, and misconduct, are always, in the last analysis, the outcome of mental life." Now, one cannot have "inner psychological effects" unless there is an inner psychological "something" to be affected. That "something" is the innate mental constitution of the individual.

> "Our days, our deeds, all we achieve or are,
> Lay folded in our infancy; the things
> Of good or ill we chose while yet unborn."—*Trowbridge.*

"Temptation." Mercier tells us, "is strictly relative to the person tempted. Temptation is relative to disposition, and that circumstance which is strong temptation to one is but weak temptation to another, and no temptation at all to a third." If, then, the individual's innate capacity for social adaptation is accepted as of paramount importance, it is reasonable to concede the claim of Porteus, "that so far as mental diagnosis is concerned, the value of any 'test' score lies in predicting how well a person will adapt himself to his social environment."

The fault of the "Binet" scale (and its modifications) seems, in this connexion, to be in the premium which they place upon a purely verbal morality. The young delinquent is accustomed to live by his wits, and the ethically beautiful response he may make to such an inquiry as "what would he do if he had broken something which belonged to somebody else?" may bear no relation to the course he would actually pursue did the circumstances indeed arise.

Burt remarks of the maze tests "it is perhaps in estimating social, as distinguished from educational efficiency, that they will be found most helpful." This is indeed their particular advantage. The very essence of the tests is to stress the value of prudence, forethought, and ability to profit from mistakes, which are fundamental to social adaptability, and accumulated evidence tends to show that they bear a relatively higher average correlation with social capacity and industrial ability. It was for this reason that it seemed of interest to apply them to young men about to take their place in the outside world again, after some two years under training in a specialised environment. Each one had been tested by "Terman" at the time of reception, but the maze tests were carried out under more favourable conditions, since, instead of being at the commencement of what must seem to the youthful mind a long period of incarceration in strange surroundings, the individuals had long since become familiarised with their environment and were rapidly approaching the longed-for liberty. The ages of the lads involved ranged approximately from 18 to 22 years, and the offences committed were mainly, though not wholly, of the "stealing" or "breaking and entering" type. The results, summarised into 13 age groups, appear as follows, viz.:—

Below 5 .. 1	9 to 9½ .. 9	14 to 14½ .. 6
5 to 5½ .. 1	10 to 10½ .. 16	15 to 15½ .. 5
6 to 6½ .. 2	10 to 11½ .. 17	16 .. 5
7 to 7½ .. 3	12 to 12½ .. 19	
8 to 8½ .. 4	13 to 13½ .. 12	

It will be observed that only 16 of the 100 reached the level of 14 and over, as compared with the experiences of Grierson and Rixon, who found an average mental level of 14 years in 200 prisoners tested by "Terman" at Brixton. In no case did any lad achieve a Porteus score higher than his "Terman" level, but in a number of cases the Porteus score was lower. Occasionally, the fall was striking, and at least one case is worth individual mention. The lad concerned reached the level of 16½ years "Terman," but at the mazes could rise no higher than 9. In the Institution he usually produced a favourable impression upon the inexperienced but was not trusted by the seasoned officers. A very short time after his release, his behaviour was again giving cause for anxiety, though he had avoided actual arrest.

It is far from the writer's intention to imply, thereby, that social salvation or damnation is infallibly indicated by the "Porteus" or any other tests, but, from close consideration of the everyday behaviour both at work and at play, of the lads tested, there does seem some ground for believing that in this particular relationship the maze tests have advantages over the verbal types of test. These latter ask the delinquent to state what would be his reaction to certain hypothetical social circumstances, and it is a little ironical that one of the questions put to the candidate is "why should we judge a person more by his actions than by his words?" for "the word of the delinquent," to quote Burt once more, "has always to be verified." The maze tests, on the contrary, necessitate that the individual should act in the face of a concrete situation, in such a manner as must reveal with some faithfulness the presence or absence of qualities essential to social success.

The glib talker may, by the "Binet" scale, produce quite a false impression of his social stamina, and in such cases the additional application of the Porteus tests may materially assist the examiner in coming to the conclusion that the most judicious admixture of sunshine and rain can never turn tares into wheat.

This article is published with the permission of the Prison Commissioners, but does not necessarily represent their views.

Clinical and Laboratory Notes.

A CASE OF ATRESIA OF THE VAGINA.

BY ARTHUR A. GEMMELL, M.B., B.CH. CAMB., F.R.C.S. EDIN.,

HONORARY ASSISTANT SURGEON, LIVERPOOL AND SAMARITAN HOSPITAL FOR WOMEN; HONORARY ASSISTANT GYNÆCOLOGICAL SURGEON, DAVID LEWIS NORTHERN HOSPITAL, LIVERPOOL.

CASES of atresia of the vagina (as distinct from cases of so-called imperforate hymen) in association with full development of the internal genitalia are rare. Therefore the following appears worthy of record.

M. D., aged 18, complained that she had never menstruated, but had had attacks of abdominal pain for 14 months. The attacks lasted a fortnight and recur at monthly intervals. The pain is felt in the hypogastric and sacral regions, is so severe that it causes vomiting, but is relieved by hot applications and brandy. The attack in which the patient was seen had lasted two weeks.

On examination she proved to be a poorly developed girl for her age with six digits on the right hand and each foot. The secondary sex characteristics were well marked. There was a mass in the abdomen extending from the symphysis pubis to the umbilicus and the upper part of this felt like the body of the uterus. The external genitals were normal, but what was at first taken to be a vaginal orifice with a hymen proved to be a patulous urethral orifice situated in a more posterior position than normal. There was no vagina. Examination per rectum confirmed that there was no vagina, and showed that the lower pole of the mass, which was cystic, extended to within about three inches of the perineum.

It was considered wiser to attempt to reach the retained menstrual fluid from below, and after it had drained away determine exactly what parts of the sexual apparatus were present and then decide on a final course. Accordingly a transverse incision was made in the perineum below the urethral orifice, but anterior to the fourchette. Blunt dissection was cautiously carried out through moderately firm tissue, the direction being guided by keeping a sound in the urethra and a large dilator in the rectum. Finally the lower pole of the mass was reached and opened and menstrual fluid escaped. A tube was passed along the track formed by dissection and stitched to the vulva. The patient had been having rises of temperature before the operation and continued to have them after. A dilator was passed along the track daily and menstrual fluid escaped, with pus on one or two occasions. Five weeks later discharge from the track had ceased and there was still an abdominal swelling half way to the umbilicus but nothing suggestive of a uterine body, and the whole mass was fixed. During this time there had been no menstruation and no attack of pain.

On opening the abdomen the bowels and omentum were found adherent to the abdominal wall and to one another, evidently shutting off the retained blood which was found in the peritoneum. These were separated with considerable difficulty and during the process about an ounce of pus escaped from a pocket in the region of the right appendage. By further dissection the appendages were freed, the right from its normal position, the left from the bottom of the pouch of Douglas. The tubes were found to be distended with blood and the left open at its fimbrial end. The uterus was enlarged, soft, and retroverted and ended abruptly below in a firm boss, embedded in soft connective tissue. Hysterectomy was carried out, but in attempting to enucleate what was thought to be the lower pole of the cervix from its bed it was accidentally cut through, and as the patient was very shocked and all secreting tissue had been removed no time was lost in dissecting out the remaining plate. Peritonisation was carried out in the usual way but with some difficulty. The dissection from the perineum was found to have opened into the pouch of Douglas and this was kept open as a drain.

On examining the specimen the uterus and tubes were found to be distended with blood and there was a small cap of vagina about half an inch long attached to the uterus. The patient had a somewhat stormy convalescence. Fairly large quantities of pus were discharged from time to time from the perineal sinus, which was kept irrigated regularly, but there was never any suggestion of peritonitis. On examination four weeks after the abdominal operation the perineal track was found to be healed and, per rectum, there was a little thickening in the region of the stump of the right broad ligament. The patient is quite well and free from pain.

As there was definitely menstrual blood in the pelvic cavity in this case it is interesting, in view of Bailey's paper on Endometriomata [1] to speculate as to the future of this patient. Unfortunately none of this fluid was saved and examined for endometrial glands. A search of the literature has only revealed 14 cases of atresia of the vagina combined with hæmatometra, with or without hæmatosalpinges. The treatment in most cases has been abdominal operation. Where perineal drainage has been resorted to first the convalescence has been slow. Successful attempts to form an artificial vagina are recorded in five cases and the technique given by Pfannenstiel and Vineberg [2] appears to be the most hopeful.

PERFORATION OF GASTRIC ULCER DURING X RAY EXAMINATION.

BY F. W. LANG, B.SC., M.B., CH.B. EDIN.,

RESIDENT MEDICAL OFFICER, QUEEN MARY'S HOSPITAL FOR THE EAST END.

THE perforation of a gastric ulcer during a barium meal examination by X rays must be a rare occurrence. It may, therefore, be of interest to narrate the facts of the undermentioned case, in which this untoward incident actually occurred.

Clinical History.—T. W., aged 65, attended the surgical out-patient department of the hospital for the first time on April 19th last. He complained of severe pain "in the pit of the stomach, just like something gnawing at me inside." It had started about two years previously and had been periodic in nature, sometimes leaving him for intervals of up to two months. The pain came on about two hours after food, and, at first, was relieved somewhat by more food. Latterly, however, food aggravated it to such an extent that, although his appetite was good, he was "frightened to eat." During the last three weeks it had become more severe and tended to be persistent. Nausea and retching were increasingly troublesome, and recently some relief was obtained if he "brought anything up," but very little actual vomiting had occurred. Regurgitation of "sour" fluid was, however, frequent. There was no history of hæmatemesis. His bowels were constipated. He had not noticed anything unusual about his motions. His previous health had always been good and his habits very moderate. Despite the increasing discomfort, he had maintained his strength sufficiently to continue at his occupation of boiler-maker till he reported at the hospital.

Examination.—General condition good. Though thin, he stated that he had not lost weight. Slight pyorrhœa alveolaris was present. On abdominal examination there was marked tenderness and hyperæsthesia of the skin just above the umbilicus. Otherwise nothing special to note. A provisional diagnosis of "gastric ulcer" was made. A barium meal X ray examination was arranged for April 21st—i.e., less than 48 hours afterwards. When he arrived on that date he complained that the pain was more severe. The barium meal was administered and a screen examination made. He was then transferred to the table for a plate to be taken. Immediately the pain became more severe and he could not lie still for long. On examination the typical signs of perforation were present—viz., collapse, extreme abdominal rigidity, loss of liver dullness, and rapid pulse. The plate was developed and appeared to show barium escaping from the lower end of the stomach.

The patient was operated on by Mr. A. E. Mortimer Woolf one hour later, and there was found a perforated ulcer in the anterior wall at the pyloric end of the stomach, corresponding to the site disclosed by the X ray plate. There was a quantity of barium under the liver, in the immediate vicinity of the ulcer. The perforation was closed with two layers of sutures and the free edge of the great omentum was stitched over the ulcer for greater security. It was not possible to remove all of the escaped barium. The wound was closed without drainage.

The patient made an excellent recovery and was discharged on May 31st entirely free from pain and from all other symptoms.

I wish to express my indebtedness to Mr. Mortimer Woolf for allowing me to publish this case.

Medical Societies.

MEDICAL OFFICERS OF SCHOOLS ASSOCIATION.

A MEETING of this Association took place on Nov. 12th, Dr. L. R. LEMPRIERE, the President, occupying the chair.

The Management of Infectious Diseases in Boarding-schools: Discussion.

Dr. A. I. SIMEY initiated a discussion on the subject of suggested modifications of the rules usually observed in the management of infectious diseases in boarding-schools. His paper appears in full in another column.

Dr. DUNCAN FORBES (Brighton) expressed his general agreement with the opening paper. It was very rare, in his experience, for a third person infection to occur. In Brighton sanatorium there were cases of phthisis, tuberculous joints in young children, scarlet fever, diphtheria, and ordinary infectious diseases. The general nurses attended all these cases, but there had been no spread of scarlet fever or diphtheria to the children affected with tuberculous joints. It was well known that a third person, such as a nurse, might carry infection; when nursing a case of measles the disease might be carried to another child; but as a rule conveyance by a third person could almost be disregarded. In Brighton, since 1910, the disinfection of bedding had been given up, except in hotels and boarding-houses, the practice being continued in those houses when there had been cases of infectious diseases, so as to avoid the risk of an action for damages owing to neglect. Great reliance was placed on a thorough cleaning up with ordinary soap and water. In the case of tuberculosis antiseptic spraying was carried out. Since 1910 there had been no increase in the number of secondary cases in houses in the borough. No spread of infection had been traced to the clothing of scarlet fever and diphtheria patients being washed at the ordinary laundry. In some fever hospitals, however, the linen of scarlet fever cases was washed one day, and that of diphtheria cases on a separate day, but at Brighton no difference was observed, except that the linen left the laundry by a separate door from that by which it entered. He did not consider that in schools special laundries were required for the linen of patients suffering from infectious disease. He was surprised at the importance attached in the book of rules to drains as a danger factor in infectious disease, because the idea that ill-ventilated drains had a malevolent influence was now exploded. He thought much benefit would result in schools if the scholars could be taught simple decent habits of conduct, such as covering the mouth when coughing, refraining from putting into the mouth pens and pencils in common use, and their fingers also; as well as washing their hands before every meal.

Carriers of infectious diseases were often spoken of as healthy carriers, but the oftener such were carefully examined the more they would be found to have some lesion.

Dr. E. ELLIOTT, discussing the question of the conveyance of infection by the clothing, alluded to the importance of the pocket, the recipient of the infected pocket-handkerchiefs, both in a common cold and in any infectious nasal discharge. A clean handkerchief placed in the pocket would soon become contaminated. Was there any simple method of dealing with this?

Dr. E. H. T. NASH emphasised the fact that in the great public schools it was necessary to play for safety, seeing that one was dealing with such a large number of boys. The diphtheria and other carriers who were going about the country he regarded as dangerous. They should only be tolerated outside in places where they were not exposing the general public to infection. He said this though he was well aware that the actual projection of the diphtheria virus did not exceed the distance of three feet. Formalin disinfection, he considered, was efficacious, but it must be done in a moist atmosphere. He always had spraying done as well as fumigation. Having always in mind the need for a good margin of safety in these matters, because of the young and growing population being dealt with, he thought it was rather drastic to start revising the code of rules. He agreed with Dr. Forbes's views regarding drains, but thought the inhalation of foul air so debilitated the system that it became an easier prey to any infections there might be about. He was of opinion that at a future date Dr. Forbes's views would be prevalent in the country generally, but at present many responsible people lacked the courage to apply them practically. It would be well, he thought, to discuss this question jointly with the Society of Medical Officers of Health; then there might eventuate a revision of the book of rules; which was the Bible of the medical officers of schools.

Surg.-Captain P. M. MAY spoke as medical officer of a large school, though not a public one, the scholars of which were drawn from all parts of the kingdom. In that school practically every infectious disease was experienced, and there had been many epidemics. In one large epidemic there were 127 cases of scarlet fever and 107 cases of diphtheria. The Metropolitan Asylums Board were unable to take the scarlet fever cases, and the speaker had to treat them all. There were no fatalities. Diphtheria was so frequently occurring in that school that it was practically endemic. As soon as a case of it was recognised, all the boy's contacts were isolated for 14 days. Scarlet fever and measles, when once started, spread, one would suppose, very quickly, but that did not always happen. All the stipulated precautions, such as sending the clothes to the disinfector, were carried out as a safety course against criticism, though he did not agree with all of them. The record of the school in the matter of infectious disease was good, seeing that many of the boys lived in the crowded parts of Greenwich, where there was a good deal of zymotic disease.

Dr. J. YOUNG said an important question was as to whether more might not be done when the first case of an infectious disease in the school was detected. In measles one was fairly safe until the tenth day, In day-schools, if on the occurrence of the first instance of disease the school was closed for so many days, the children would develop the disease at home and there would be no school epidemic. In the case of boarding-schools, inthe winter-time the football scrimmage must be a potent source of infection.

The PRESIDENT reminded the meeting that the code of rules had been the school medical officer's court of appeal since 1884, and the advice of the medical officer was always being sought concerning disinfection. Hence in seeking to make any changes in the rules it was wise to proceed circumspectly. Still, the rules should be examined critically to see whether, in the light of up-to-date knowledge, they could safely be modified. Their whole object was to prevent the occurrence of infectious diseases, or, if they did occur, to limit their spread. So far the carrying out of the rules as laid down had been, he considered, a failure, and he was speaking with an experience of 3500 cases. In the past ten years there had been more epidemics of all exanthemata than in the preceding 20 years. The total number of cases during those two periods had been proportionately the same. And the percentage of cases among those who entered the school unprotected was about the same now as 40 years ago, except that the cases of rubella had risen 25 per cent. That was the disease concerning which most mistakes were made. Infectious diseases in schools were bound to occur, and attempts at the limitation of the incidence had not been successful, but rather harmful, as the larger the number of unprotected the bigger the epidemics and

the greater their severity. Therefore it was wise to realise how much time was wasted in long quarantine precautions. He agreed that one attack of these diseases conferred immunity against a second attack, and thought that most supposed cases of second attack were wrongly diagnosed. For example, a supposed second attack of measles was often found to be rubella. One could never know whether a case of mumps or one of varicella would produce an epidemic, and his inclination was to abolish quarantine for those two diseases. For a long time he had given up disinfection for scarlet fever and varicella. He agreed as to the importance of looking after the naso-pharynx as a precaution, and supported Dr. Simey's contention that the determining factor as to a boy's fitness to return to school was his clinical "wellness"; but a subject of measles should not be returned to school sooner than three weeks after that illness started. One public school treated rubella as if it were non-existent. The speaker thought that a varicella patient should be kept in for ten days, and when his face was clear school should be resumed. For mumps, three weeks should be allowed, because of the danger of orchitis. Certificates for return to school should either be rigidly enforced or discontinued. Catarrh was a curse of the schools; he included it in his certificates, and that had been a help. He agreed it was worth while to take special care and trouble over the first case of an infectious disease in school, though he had not been able to satisfy himself that it had done much good. He had great faith in the efficacy of a generous use of soap and water. The linen of boys suffering from infectious disease was soaked in disinfectant before being sent to the ordinary laundry, and he had not known of any cases of infection occurring among the laundry staff or their families. The incubation period for measles should be, he thought, 7 to 14 days, that for mumps 12 to 28 days, and for scarlet fever 1 to 12 days. For rubella 7 days from the appearance of the rash should be allowed if there was no persistence of nasal or other symptoms.

Dr. W. G. WILLOUGHBY (Eastbourne) said the code of rules had been of considerable use in giving the medical officer a guide. When he went to Eastbourne he found there were many private sanatoriums or institutions to which cases of illness were sent. He persuaded the headmasters and headmistresses in the borough that it would be better to allow the local authority to build blocks for the reception and treatment of cases from all over the town. It was done, the headmasters and headmistresses, through their association, paying 5 per cent. of the capital outlay. Though the present code of rules in regard to infectious diseases could not be shown to have had a very good effect, something of the kind was bound to exist. He acted in an advisory capacity in regard to infectious diseases concerning about 4000 children, and he had found that the great difficulty in the past had been the parents, because they were so keen on visiting the children in hospital. It was much better now. Recently a large experiment had been carried out in regard to quarantine, 6000 children being involved. In the old days, when a case of infectious disease occurred in a home, the other children were not allowed to attend school. Twelve years ago he removed that regulation, except in the case of infants, stipulating that the child could come to school if he or she had had the disease, whatever it was, previously. Since then the amount of infectious disease had been less than before. With regard to the practice of taking swabs in diphtheria cases, in one period no swabs were taken before patients were discharged, in a subsequent period two or three swabs of each case were taken, and only in the latter period had there been return cases of the disease. But that did not prove that the taking of swabs was not the right course; he believed it was. He quoted a case where small-pox was demonstrably traced to clothes infection; but he agreed that third person infection was very rare and unlikely. He also referred to infection conveyed by books. With regard to drains, he felt it was very important for the public health that drains should be all right; a slight sore-throat when feeling "run-down" could easily be precipitated by proximity to a bad drain.

Dr. W. ATTLEE thought a new set of rules would help to educate the public as to the importance of the disinfection of clothes, and of avoiding seeing their children because of the danger of conveying the infection to others. The idea of the school medical officer had been to play for safety, and in regard to heart disease this had been carried too far, the instructions precluding boys from participating in games and sport. The rules should certainly be made to embrace tinea and impetigo.

Dr. J. LAMBERT thought parents should be advised when their boys were ill, and every boy should be medically examined to ensure that he did not return home in an infectious state. It was found that isolation of a boy and his immediate contacts did not prevent an epidemic.

Dr. N. A. SPROTT would include in the rules regulations as to tonsillitis, influenza, and "pink-eye."

Dr. G. E. FRIEND said that 40 per cent. of the epidemics in his cognisance occurred at the beginning of the term, so that they were possibly started during holidays. He did not doubt that the epidemics occurring during term were caused by visitors. There was, at his school, a fairly numerous day staff, but he had not traced the introduction of infectious disease to them. He did not wish to see any alteration made in regard to certificates. Parotitis should be given a maximum period of 28 days. Boys with rubella were usually sent back to school at the end of a week if there was no discharge from nose or ears.

Anthropometric Graphs.

Dr. REGINALD HANSON exhibited cards for keeping records of the height and weight of children at various ages, both in actual figures and in graphs, such as he had been using for the children in the primary schools of the Duchy of Cornwall. He devised these in response to the wish of parents to keep records of the physical condition of their children from 5 to 18 years. A space in the card was occupied by hints on diet and health.

MANCHESTER MEDICAL SOCIETY

AT a meeting of this Society held on Nov. 3rd Dr. ALFRED A. MUMFORD, the President, took the chair, and Dr. J. F. WARD opened a discussion on

Spastic Paralysis in Children.

Spasticity, he said, was difficult to define, but signified an increase of muscle-tone and was an indication of an upper neuron lesion. The presence of such a lesion explained the loss of voluntary power in muscles supplied by nerves which were affected. Associated with spastic paralysis—in children more frequently than in adults—were athetosis, choreiform movement, and perverse movements. These were explained as due to unrestrained activity of extra-pyramidal tracts following a pyramidal lesion.

In children, said Dr. Ward, spastic paralysis was met with in the following conditions: (1) diplegias; (2) paraplegias of various origin; (3) hemiplegias; and (4) amaurotic family idiocy. The chief clinical manifestation of diplegia was spasticity of legs with adductor spasm; this often was not recognised until the child was several months old. Some mental defect was present in most cases, though very variable in degree. Sometimes, also, there was blindness, either cortical or due to optic atrophy, and convulsions might occur, though not as frequently as in hemiplegia; involuntary movements were also less common. A tendency towards improvement was noted in a large proportion of cases. There were two principal schools of thought regarding the ætiology, said Dr. Ward; the first school attributed the diplegia

to intracranial hæmorrhage or injury, whilst the second regarded it as a result of primary neuronic degeneration. Little had believed that asphyxia was the cause; causes suggested later were: meningeal hæmorrhage (McNutt, Gowers, and Osler); prematurity (Prissaud); and intra-uterine degeneration of neurons (Freud and, later, Collier). Sixty per cent. of the cases were associated with abnormal labour—difficult labour, precipitate labour, asphyxia, or prematurity. The work of Herbert Spencer, Eardley Holland, and others had shown the great frequency of intracranial hæmorrhage in stillborn infants and in those who died shortly after birth. Injury and asphyxia frequently occurred together in difficult deliveries. The hæmorrhage was chiefly intradural and most frequently diffuse, but might be only petechial. Many cases soon proved fatal, but those that recovered might not show evidence of involvement of pyramidal tracts for some months because these tracts developed later. Post-mortem evidence supported Collier's view, but Schwartz had shown that atrophic sclerosis might follow hæmorrhage. Syphilis was not an important cause; the Wassermann reaction was negative in most cases and other symptoms of congenital syphilis were absent.

Infantile hemiplegia, Dr. Ward continued, was probably of quite different pathology in most cases. The onset was generally later than that of diplegia, and was most common between the age of 6 months and 2 years. Convulsions and febrile disturbances were observed at beginning in most cases. These convulsions might be due to the same cause as the hemiplegia, but possibly the hemiplegia was due to a vascular lesion resulting from the congestion during the convulsion. There was frequently a history of infectious disease shortly before onset. Spasticity might be due to vascular lesions, to atrophy or sclerosis, or to porencephalus. Atrophy and sclerosis were probably sequels to encephalitis, and there was some evidence to suggest that this was a polio-encephalitis due to the same organism as poliomyelitis; the evidence, however, was not complete and "encephalitis" was rather a loose term. The treatment of spastic paralysis might be non-operative, by such means as massage and re-education, or else operative. Re-education was most important; massage might soothe hypertonic muscles, but its effect could only be very transitory. Electrical treatment was wholly undesirable. The operative treatment might consist of division of posterior nerve roots (Förster); operations on peripheral nerves (Stöffel); tenotomy; or sympathetic ramisectomy (Hunter and Royle).

Mr. E. S. BRENTNALL dealt with the principles of treatment and emphasised the importance, and in some cases the difficulty, of forming at the outset a fair estimate of the patient's educability. In very young children the treatment had to be left largely to the parents, and should consist of simple stretching of the tight structures and elementary postural training. The use of a foot-splint during sleep was essential, but prolonged immobilisation and splinting were undesirable. Activity and its educative results were of the greatest importance to these children. In older patients treatment should consist of physical training and should aim at developing the sense of balance and the coördination of the child. Both physical and mental improvement could be anticipated in patients who were educable. Operative treatment was directed almost entirely to the relief of contractures. It should only be undertaken in children with a fair degree of educability, and not before promising efforts to stand and walk could be made. Operative treatment in itself, said Mr. Brentnall, did not improve the sense of balance, and might, indeed, interfere with it if the child was long immobilised. The most useful methods adopted were the division, lengthening, and transplantation of tendons, and the Stöffel operation. Different methods would be found necessary in different parts of the limbs. In the lower limb operative treatment in suitable cases could be expected to produce distinct improvement in gait and activity. In severe spastic affections of the hand he doubted whether any tendon operation or nerve section was of real benefit or could restore any degree of functional capacity to the limb.

Prof. J. S. B. STOPFORD confined his remarks to the work done on the sympathetic innervation of striated muscle, reviewing the research of Hunter and Royle and others in this field. After submitting proof of the existence of the sympathetic supply of muscle he discussed the functional significance of the fibres reaching the muscles from the autonomic nervous system. Although, he said, the theory of muscle-tone propounded by Hunter and Royle had been severely criticised, their experimental results demanded further consideration and research; there was evidence that sympathetic denervation had an effect upon muscular activity and it was necessary to investigate fully what that effect was. It might be, as had been suggested, an indirect effect; the researches of Orbelli on the influence of the sympathetic upon fatigue were significant and might lead to a correct interpretation of the experimental findings. Several surgeons, said Prof. Stopford, who had described ramisectomy as of no practical value, had acknowledged some effect upon muscular activity in at least a proportion of their cases. Failure to obtain useful results by ramisectomy must not prevent the following-up of experimental research. For the immediate future it would be wiser probably to confine attention to a careful analysis of the effects of sympathetic denervation, and a review of the present position suggested that this might have far-reaching results.

LIVERPOOL MEDICAL INSTITUTION.

AT a meeting of this Institution on Oct. 28th, Mr. G. C. E. SIMPSON read a paper on

Obstruction of the Duodenum.

Besides ulcer, he said, there were other duodenal lesions which frequently caused indigestion. These included diverticula, involvement by growth or inflammation from neighbouring structures, tuberculous stricture, and obstruction by bands and adhesions from tuberculous lesions outside the duodenum. Cases of congenital malposition also occurred, and in one of these, he said, he had met an appendix which controlled the duodeno-jejunal flexure. After referring to Nagel's case of congenital diaphragm of the duodenum in a patient who survived to the age of 72, Mr. Simpson quoted a case of his own in which a man of 24 had had a stricture, two inches long, and half an inch in diameter, in place of a pylorus. In another patient there was a biliary cyst invaginating the wall of the duodenum from the biliary papilla to the superior mesenteric artery, where it caused obstruction; the cyst contained about 30 ounces of fluid with elements from bile and pancreas and a few stones, and a duodenal ulcer was also present. In these cases the symptoms of indigestion had been chronic but slight for years, and had then become more acute, with dilatation of the stomach. Flatulence had been troublesome.

Passing on to the subject of ileus, Mr. Simpson spoke of a case of chronic duodenal ileus in a girl of 12, which was treated by a belt, and referred to other early cases treated by colopexy. Gastro-enterostomy, he said, had been done in cases where the symptoms were particularly suggestive of ulcer, and where there was marked hyperchlorhydria; most of the patients had been males and the results were good. Of 14 patients treated by duodeno-jejunostomy half were cured or had only slight discomfort; two were done recently and three he considered definite failures. In view of the long-standing history and previous and associated operations, these results were satisfactory. All the cases showed enteroptosis.

Mr. Simpson then went on to consider bands from the gall-bladder and ducts to the duodenum and colon. Apart from adhesions definitely attributable to inflammation, such bands, he said, were common

and they were often the only lesion present where the symptoms were suggestive of duodenal ulcer or gall-stones; in such cases their release was beneficial. Proliferative changes in reaction to strain were responsible for such bands, though often the basis was of congenital origin. Here, again, there was usually enteroptosis.

Mr. Simpson described a case in which there was duodenal delay and prolapse in the obstruction, and appeared to be at the duodeno-jejunal flexure, probably from the duodeno-jejunal band. In general, he said in conclusion, obstruction of the duodenum tended to give a picture with periodicity. The pain was often relieved by food or by hot drinks. Both the intervals and the duration of the attacks were different from those of duodenal ulcer, the attacks being short, and flatulence was a constant feature.

Dr. T. W. WADSWORTH read a paper on the Clinical Significance of Cardiac Murmurs, in which he described the physical factors responsible for murmur production and the various theories about the presence of murmurs where no anatomical or pathological causes could be found. The term "accidental," he thought, should be employed when describing murmurs of this type; they could be qualified by such names as "hæmic" and "cardio-respiratory" when their ætiology was made clear.

EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

A MEETING of this Society was held on Nov. 3rd, Prof. WILLIAM RUSSELL, the President, in the chair.

Mr. HENRY WADE read a paper on

The Treatment of Tumours of the Urinary Bladder.

He stated that when blood appeared in the urine suddenly, unexpectedly, and painlessly in a person apparently healthy, it was probably due to a tumour of the bladder. Ninety per cent. of all such tumours developed papilliform ingrowths which bled when the bladder contracted, whether they were innocent villous papillomata, malignant papillomata, or primary papillary carcinomata. An exact diagnosis could only be made by cystoscopy or by removing part of the growth with a cystoscopic rongeur. The latter method was occasionally fallacious, as in the borderline case the part removed might be innocent, whereas at the base of the growth definite malignant changes might be present. The appearance on cystoscopy almost always made exact diagnosis possible.

The treatment of tumours of the bladder, said Mr. Wade, was determined by the nature, size, and extent of the growth. There was only one treatment indicated for a benign villous papilloma of moderate size—namely, fulguration. Fulguration of such a tumour should be painless. A local anæsthetic might be used, but, where necessary, it was better to give a narcotic, such as morphia, before examination. The treatment was devoid of risk to life, and could be carried out for the wage-earner without his losing an hour's work. It was especially useful in preventing the development of the secondary daughter tumours, frequently seen after cystotomy. In a few selected cases, a general anæsthetic might be given, especially where the mucous membrane in the neighbourhood of the tumour needed cauterisation. If the slough formed after fulguration was large and not voided, it might form the nucleus of a stone. Where the villous papilloma was of a very large size, it was unsuitable for removal by fulguration, and such cases should be treated by suprapubic cystotomy and removal of the growth. To minimise the risk of dispersing and implanting the cells of the tumour by the necessary handling of the growth, the bladder cavity and later the wound, were filled with a 1-1000 silver nitrate solution. After such an operation cystoscopy should be done at regular intervals for at least a year. If small daughter tumours were discovered, they should be destroyed by fulguration.

For primary carcinoma of the bladder, continued Mr. Wade, fulguration was not to be recommended; application of radium was said to give good results occasionally. The best treatment was to excise the entire growth, if possible. Those on the fundus of the bladder were most favourably situated for such excision, but when tumours were found in this position it was important to be sure that they were not due to invasion of the bladder by neoplasm of the intestine, ovary, or other organ. Where the base of the bladder was involved, partial cystectomy, with the removal of a portion of one ureter, might be done, the divided ureter being implanted into the bladder, or left in situ; the granulating cavity in which it was situated later formed a natural diverticulum of the bladder. Where a primary carcinoma was intrinsic, but could not be removed without excising the entire bladder, this very grave operation was warranted in view of the pain the patient would inevitably suffer without it, on account of recurring painful, spasmodic contractions of the bladder, which grew worse and worse. These contractions persisted after the ureters had been implanted into the loins or bowel, and therefore no palliative operation was possible. When total cystectomy was performed, it was most satisfactory to implant the ureters into the loins, the patient afterwards wearing an apparatus to collect the urine. In the male the prostate and seminal vesicles were preferably removed at the same time. The shock of the operation was not unduly severe. When an improved technique for bilateral implantation of the ureters into the bowel had been worked out, this method would probably be adopted instead. The results of the Coffey-Mayo technique in extrophy of the bladder suggested that it might be safely employed in bilateral transplantation.

A discussion followed, in which Sir DAVID WALLACE, Mr. J. W. DOWDEN, and Mr. J. J. M. SHAW took part.

Dr. STANLEY DAVIDSON read a paper entitled

An Investigation into Non-specific Therapy.

Non-specific therapy, he said, might be defined as the production of a therapeutic effect by the parenteral introduction into the body of some agent which had no biological relationship to that responsible for the infection. To-day there was still great diversity of opinion about its efficacy, and the process by which it produced its supposed beneficial results was still unsettled. It was believed that it might act in three separate ways: (1) by mobilising the defensive enzymes; (2) by producing a leucocytosis; or (3) by the universal stimulation of all body cells. This could only be produced by the intravenous injection of foreign protein in toxic doses. Protein shock must be produced if beneficial results were to be expected—i.e., a severe local and general reaction should follow injection of the protein. It could not be maintained, said Dr. Davidson, that non-specific therapy was in any way comparable to specific therapy as an efficient measure. It was weak in action, inconstant and variable in occurrence, and temporary in duration.

Prof. T. J. MACKIE discussed Dr. Davidson's results from a bacteriological point of view.

Dr. ALEXANDER GOODALL stated that in a small percentage of cases miraculous results were obtained by the use of non-specific agents, either protein or preparations of *B. typhosus;* more might be done to search for that part of the protein molecule which was therapeutically active.

Dr. JOHN EASON claimed that a large percentage of patients with rheumatoid arthritis showed marked improvement, which had encouraged him in the constant use of peptones.

The PRESIDENT had not found such benefits, and considered that peptone-shock was often a definite danger.

After other speakers had taken part in the discussion, Dr. DAVIDSON, replying, agreed that the clinical improvement noted in some cases should encourage further endeavour to ascertain wherein lay the benefits of non-specific therapy.

Reviews and Notices of Books.

THE FUNCTIONS OF THE BODY.

An Outline of Physiology. By V. H. MOTTRAM, M.A., late Fellow of Trinity College, Cambridge; Professor of Physiology in the University of London. London: Nisbet and Co., Ltd. 1926. Pp. 260. 7*s.* 6*d.*

Prof. Mottram points out in the preface to this volume that it arose partly as the result of a determination to give students of medicine at the beginning of their physiological course a bird's-eye view of the boundaries and important features of this science as a preliminary to a more detailed survey. His original conception, however, has been somewhat altered into an attempt to put the modern views of physiologists in a simple and untechnical form in which they could also be understood by a larger public. The volume is now intended, therefore, to serve as an introduction to physiology, not for the medical student only, but also for students of nursing, domestic science, teaching, and massage, and for that section of the general public which is eager to know something of the way in which the body works. The book is divided into eleven chapters, all of which are written with a gift of expression and wealth of example and analogy calculated to hold the reader's attention and interest without imposing upon him the exhausting concentration necessary for the digestion of large modern text-books. The study of function proceeds in an orderly sequence from that of the nervous system, sensory and effector apparatus, through that of food, its digestion, transport, oxidation, and excretion, to an account of the reproductive system in the lower and highest forms of life. One chapter is devoted to a study of the internal secretory organs; and the manner in which the secretions of these glands correlate the various activities of the animal and integrate them into an intelligible and purposeful whole is clearly described. A short summary is appended to each chapter, and references are given to the more advanced treatises pertinent to the subject under discussion.

The salient facts of physiological knowledge have been gathered together in a small compass and have been placed before the reader in an entertaining manner. The result is a volume as delightful as it is informative.

HANDBOOK OF DISEASES OF THE RECTUM.

By LOUIS J. HIRSCHMAN, M.D., F.A.C.S., Professor of Proctology, Detroit College of Medicine. London: Henry Kimpton. 1926. Pp. 403. 30*s.*

THIS volume begins with a practical account of the anatomy of the rectum, followed by details of methods of examination. Among those illustrated is the inverted or Hanes's position for sigmoidoscopy, which must be extremely unpleasant for the patient; the need for it does not seem clear when the knee-chest position is so satisfactory. The motto of this chapter, and in fact of the whole book, is that the slightest rectal symptoms necessitate a thorough examination if mistakes of omission are to be avoided. The technique of local anæsthesia is clearly described; the author prefers a ½ per cent. solution of novocaine, or ½ per cent. quinine-urea in cases where suturing is not required. Sacral anæsthesia, using 30–60 c.cm. of 2 per cent. novocaine is advised for the more extensive operations and has apparently given a high percentage of good results. Constipation and obstipation are discussed and the operation of rectal valvotomy for section of hypertrophied Houston's valves is stated to give satisfactory results in suitable cases. This operation is not generally accepted or practised in this country. In the section on pruritus ani the general failure of treatment by vaccines as advocated by Dwight Murray is admitted. The operation which is recommended of undercutting the perianal skin by two median incisions anterior and posterior to the anus does not impress us as being a good modification of Ball's operation; it would appear impossible in this modification to section the sensory nerves of the anal canal up to the level of the external sphincter, which procedure is the essence of the Ball's operation.

In dealing with the treatment of fissure and abscess certain points made by the author call for criticism. The deep, narrow "trench" which the author leaves after incising a fissure must cause the patient more post-operative pain and difficulty of dressing than the flat, shallow, lozenge-shaped wound. In regard to opening abscesses in the perianal region, the old advice to make a single straight incision, packing with gauze and subsequent daily separation of the skin edges, is here proffered. The wide excision of skin margins leaving a large circular or oval wound is a much better and more certain way, and far less painful to the patient. The chapter on fistula contains some good radiographs of fistulæ after injection of bismuth paste, but for the most part the photographs illustrating this subject are unsatisfactory, and would be better replaced by diagrams. Although the author admits good results with the injection treatment of internal piles, with not more than 25 per cent. of recurrences in from one to three years, he now prefers removal under local anæsthesia as being a more satisfactory and surgical procedure. The technique is described. A chapter on dysentery is contributed by Dr. John L. Jelks. The major operations, such as those for cancer of the rectum, are not described, the book being written solely to describe methods of diagnosis and treatment that can be carried out in the consulting-room. It is unlikely that in this country some of the operations illustrated, such as for prolapse and fistula, would ever be done except in a hospital or nursing home. Perhaps we are fortunate in that our patients are mostly willing to submit to a less ambulatory line of treatment.

This work is particularly valuable in showing the possibilities of local anæsthesia in proctology. In this country many cases of rectal disease operated upon under general would be better done under local anæsthesia. For instance, in operations for hæmorrhoids, post-anæsthetic vomiting may cause the formation of large œdematous tags at the anal margin. Details of the technique used are clearly set out. The book is a record of the views of an expert proctologist which will be read with profit by everyone interested in the subject.

CHRONIC DEAFNESS.

The Treatment of Chronic Deafness by the Electro-phonoïde Method of Zünd-Burguet. By GEORGE C. CATHCART, M.A., M.D., Consulting Surgeon to the Throat Hospital, Golden-square. London: Humphrey Milford, Oxford University Press. 1926. Pp. 88. 4*s.* 6*d.*

Dr. Cathcart begins this little treatise with a good and spirited defence of empiricism, as distinguished from quackery, pointing out that it is possible to cure a disease of which we do not know the cause and that, conversely, to know the causation is not necessarily to know how to cure it. But he rather spoils his case by the overstatement that the members of the medical profession "are often afraid to try a new treatment lest their fellow members should hale them before the General Medical Council for quackery." This is wrong, and Dr. Cathcart should know that no medical practitioner could be so "haled" merely for trying a new treatment—indeed, a section of the Medical Act, 1858, expressly contradicts such an interpretation of the Council's duties.

The first part of the book is concerned with the prevention of deafness; the chief points insisted upon being the more frequent and more thorough removal of adenoids, and the more frequent incision of the drum in catarrhal, as distinguished from suppurative, otitis. The author is on firm ground here, but damages his position with such a sentence as this: "It is also true that adenoids sometimes

grow again, especially if the child gets any of the exanthemata or any diseases involving the naso-pharynx, such as diphtheria or mumps, as the high temperature accompanying these diseases makes the adenoid tissue hypertrophy." There follows a historical summary of the development of re-educative methods, especially that of Itard and the oral method of Urbantschitsch, and the Zünd-Burguet instrument is reached just half-way through the book; a small-scale illustration of the apparatus is included, but a diagram on a larger scale would have been a valuable aid in following the text. The instrument is actuated by electricity and is capable of producing, in their desired intensity, sounds extending over five octaves, passing through all the vibrations from 80 to 3500; these sounds are conveyed to the ears by ear-pieces, like those of a telephone, and it is the re-education by these sounds which forms the treatment. Both ears are treated separately, three to six minutes at a time, daily or twice daily; if no improvement results after 12 treatments the case is pronounced hopeless; if there is improvement the full course of 30 treatments is proceeded with. Improvement lasts, as a rule, from six to nine months, when another course is required. This is, of course, a drawback, but, if improvement be considerable, no deaf patient will grudge all the time and money he can spare.

The book adds little to the author's paper, published in THE LANCET last year [1]; he then gave his report of 100 cases treated, divided equally between cases of nerve-deafness, chronic otitis media, and otosclerosis; of 34 nerve-deafness patients 28 improved, of 33 otitis media patients 22 improved, and of 33 otosclerotics 18 improved. It is noticeable that nerve-deafness gave the best results, and it is difficult, in the absence of details, to realise of what kind of nerve-deafness the 34 cases consisted; Dr. Cathcart specifically says that he has not included any cases of neurasthenic deafness, or any cases caused by drugs (such as quinine or nicotine), or by syphilis, or due to war injuries, and we presume that he has excluded hysterical cases. Outside these categories nerve-deafness is not very common except among boilermakers and kindred trades. His list includes two girls of 9 and 12 years of age; further details of these cases would have been of interest. Dr. Cathcart further allows no tests to be of any value except the voice and the whisper. He tells a story of an otologist whose whisper varied greatly before and after treatment; we are sure that Dr. Cathcart's voice is under better control than this, but it is not an exact method, and we wish that results could be tested with greater mechanical accuracy; could it not be done satisfactorily with the audiometer, an instrument already described in our columns? (THE LANCET, 1925, i., 945).

We do not wish to be too critical of a comparatively untried method, though it involves a great expenditure of time on the part of aurist and patient; these are not insuperable drawbacks to any treatment, provided it can be proved to give adequate relief in a sufficient proportion of cases.

DAME LOUISA ALDRICH BLAKE.

By Lord RIDDELL. London: Hodder and Stoughton, Ltd. 1926. Pp. 91. 6s.

Lord Riddell in writing this short biography has aimed at revealing the subject's personality, at saying what she was as well as what she did, and at explaining how she was affected by her surroundings. The result is a sympathetic piece of work, and a small volume which Dame Louisa Aldrich Blake's friends and admirers will like to possess. The description of her parentage and early training prepares us with unusual aptness for the manner of woman that she became, and we can see how, almost inevitably, she turned to the profession of medicine as providing the best chances for the realisation of her ideals. An exceptionally successful career in the schools was followed by the tenure of a series of important posts at the Elizabeth Garrett Anderson and Royal Free Hospitals. In 1914 she was elected to the post with which her name is most closely associated, that of Dean of the London (Royal Free Hospital) School of Medicine for Women, and in that capacity she proved herself an admirable administrator, a great person at committees, and, to the considerable surprise of her colleagues, a financial adept who could make her theories of progress keep in line with the messages of bookkeeping and of balance-sheets. How the school prospered under her, how honours came to her, as well as the more intimate aspects of her character are well set out by Lord Riddell in a sketch which, as is explained in a prefatory note, has been deliberately made a short one, but is none the less vivid and complete within its limits.

[1] THE LANCET, 1925, i., 968.

ROENTGEN INTERPRETATION.

Third edition. By GEORGE W. HOLMES, M.D., and HOWARD E. RUGGLES, M.D. London: Henry Kimpton. 1926. Pp. 326. 21s.

THIS excellent little book has now reached its third edition. The less useful illustrations have been replaced and a considerable number of new ones have been added, so that they now form a valuable adjunct to the text. Parts of the text have been revised and a general account of Graham's method of gall-bladder investigation has been included. In the chapter on chest work some account is also given of the use of lipiodol. A chapter on Fluoroscopic Technique and Protection has been added.

This is one of the best introductory text-books on radiology that we know; the authors have given a clear account of the various radiological methods employed and of the pitfalls that await the unwary, whilst surprisingly little has been omitted. The bibliography at the end of each chapter provides for those who require a more detailed account than it has been the author's intention to give.

JOURNALS.

THE PRESCRIBER for November is a special number devoted to rheumatic disease, with particular emphasis on their economic aspect. The prefatory part recognises that the term includes affections of a substantially different character, that tonsillar sepsis plays a prominent part in the ætiology of acute rheumatism, and that the treatment of chronic rheumatic diseases in general is entering on a more hopeful phase. The suggestion is approved that every large city ought to provide institutional treatment where rheumatic children can enjoy sunlight and fresh air with controlled rest over many months. Chronic rheumatism is regarded as having in part a climatic distribution, hence an effort should be made to compensate unfavourable climatic influences.—Dr. M. B. Ray describes the inflammatory connective tissue reaction characteristic of fibrositis, the nodules varying in size from a large pin's head to a pea, and he advocates early massage as a means of breaking up and dispersing these nodules and promoting free circulation of lymph. Fibrositis, he admits, is a veritable pitfall to the careless diagnostician.—Writing on osteo-arthritis, Dr. G. L. Kerr Pringle attaches importance to the observation that sterile synovial fluid removed from the knee-joint of an early case sets up degenerative changes when injected into the joints of an experimental animal, thus demonstrating the presence of toxic substances.—Mr. A. G. Timbrell Fisher, describing the surgical treatment of this disease, shows that treatment based on physiology and pathology holds out hope of preventing disability.—Dr. G. A. Allan estimates that there are 50,000 school-children already subject to organic heart disease, to whom salicylates may prove harmful by shortening the period of rest in bed; rheumatic carditis shows a predilection for children of the poorer classes who live in damp houses, and for them a residential hospital-school is the best after-treatment yet evolved.—Dr. J. L. Llewellyn discusses the relation between goitre and rheumatism, having found that acute rheumatism in the child of a goitrous mother

may be rebellious to salicylates but yield rapidly when thyroid is superadded. Iodine prophylaxis in goitrous regions will, he thinks, diminish also the incidence of acute and cardiac rheumatism.—Dr. A. G. Watson has found ultra-violet ray therapy of much benefit in rheumatic conditions, and Dr. J. B. Burt considers that natural mineral waters may have a specific action on certain forms of rheumatism. The symposium ends with a memorandum on spa treatment for insured patients.

TOBIAS SMOLLETT AND THE HUNTERS.[1]

IT is curious that a writer, as original, and, indeed, famous, as Tobias Smollett, should have been so much of a mystery to his own generation. He wrote little of himself, although in one place he denies that he has been personally through the blackguard scenes which he describes so brilliantly in his novels. He declares himself no friend to the Bohemianism about him. A man of family and, for his day, well equipped in education, he is neither a Pickle nor a Random, but much of a Jerry Melford—we trust that Humphry Clinker is still familiar reading. But he suggests Grub-street in his perpetual monetary difficulties, and his few discovered letters tell us little about his life save that he is for ever trying to raise loans.

The letters, some 74 in number, counting the description of a letter known to exist, have been admirably reproduced and annotated by Prof. Edward Noyes, of Yale University. Many of them are addressed to medical men—Dr. Macaulay, the husband of the lady historian, Dr. John Moore, and notably to the brothers William and John Hunter. The longest of the letters is, indeed, addressed to William Hunter, and one of the best shorter ones, reproduced in facsimile as a frontispiece in the present volume, is to the immortal John. The Hunters were his friends and patrons, and Jesse Foot, in the malicious way which he employed always in dealing with the Hunters, has suggested that Smollett wrote much of their work, not only in the *Critical Review* during the controversy with the three Monros, but at later dates. "I only attribute the keen conduct of the disputes on the part of the Hunters," says the pleasant Jesse in his "Life of John Hunter," "as they are to be found in the *Critical Review*, to the disinterested assistance of Smollett. I do not mean to be understood in saying that Smollett extended his services further," adding immediately "this episodical digression does not impair in the least the force of my general assertion, that John Hunter never was the author of any production which appeared under his name." The physician-novelist figures in a very clever sketch by Barber Beaumont, which is one of the satiric illustrations to Foot's own copy of the "Life" now in the Wellcome Historical Museum. He is shown writing to the dictation of John Hunter, who stands anxiously at the foot of a table while William sits by also apparently much interested. The likenesses are excellent and the cartoon is called "The Conspiracy."

Five very interesting letters to William Hunter, reproduced by Prof. Noyes, the originals being in the library of the Royal College of Surgeons of England, contain accounts of his travels in the south of France in search of health. He discovered Nice, the climate of which suited his constant cough, and has embodied the contents of this, the longest letter in the collection, in his "Travels," where it appears in a revised form. "On that part of the Rampart," he writes, "which faces the Mediterranean you enjoy summer all the year." He consulted Dr. Antoine Fizes, "the Boerhaave of Montpellier," who prescribed for him a kind of soup ("Bouillons of Land Tortoise"), opiates at night, and a course of goat's milk. He suffered from an obstinate ulcer, was very rheumatic, but was supposed by Fizes to be phthisical; but Smollett calls Fizes, though he enjoyed a high reputation as observer and therapeutist, "an old sordid scoundrel, and an old woman into the bargain." William Hunter was a generous benefactor to Smollett, and upon a letter of the latter containing a promise to repay a loan of £50, William writes: "In case of my death I desire my executors will not make any demand upon Dr. Smollett, because I sent the money to him as a present, never meaning to take it again." "It is pleasant," comments Prof. Noyes, "to record this passage of friendship, and to show that Scots may be generous as well as thrifty!" In August, 1763, Smollett writes to John Hunter from Boulogne, signing himself "with the most perfect Friendship and Esteem, Dear Doctor." The MS. of this interesting letter is, like many others, in America, and is the property of Prof. Tinker, who is an authority upon Smollett. The novelist refers to John Hunter's friendship with the Earl of Hertford and desires him to present "my most respectful compliments to him, and let him know that the books are restored." Lord Hertford was English Ambassador in Paris, and had been instrumental in getting Smollett's books, impounded at Boulogne, restored to him.

In another long letter Smollett says that this is the twentieth day that he has bathed in the sea, and later on refers to John Hunter as a book collector "glad to have every curious book on the face of the Earth. But I should be afraid of sending you some Books," he adds, "which you may have already." John Hunter's books were probably embodied in the sale of his effects in 1796, which his widow was driven to sanction in order to support herself; in the two sale catalogues of that year setting out Mrs. Hunter's curiosities and books, we find dictionaries of various languages, classics such as "Don Quixote" in an old edition, and learned works of all kinds, obviously of Hunter's collecting. It was John Hunter who suggested that the Library of the Corporation of Surgeons should be started, and he proposed sending books to it which have never been traced in the Library of the Royal College of Surgeons. There are some 500 items in one of the Ann Hunter catalogues of books now in the British Museum, and it seems quite incorrect to suppose, as has been done, that the volumes were negligible or nearly so.

In a grimly humorous short letter to John Hunter, dated from Leghorn in January, 1771, Smollett wills his body to the great surgeon. Subject to Mrs. Smollett's consent, he says, "you shall receive my poor carcase in a box, after I am dead, to be placed among your rarities. I am now so dry and emaciated, that I may pass for an Egyptian mummy, without any other preparation than some pitch and painted linen, unless you think I may deserve the denomination of a curiosity in my own character." The letter is cited by the late Thomas Seccombe in the "Dictionary of National Biography." Mr. Seccombe's remains the best-known life of the medical novelist. The letter is, perhaps, one of the first of those sent to the conservators of the Hunterian Museum from persons anxious, in the interests of science, to leave their bodies to the Museum. There are several of these missives among the papers left by Sir Richard Owen, but as the senders probably died where their wishes could not be attended to the bodies were to all appearances not delivered in Lincoln's Inn-fields. Prof. Jeffrey Bell, the comparative anatomist, actually left his body to the College in 1924, and the skull of this once familiar character now forms part of Hunter's collections. Smollett is buried at Leghorn, near which he died in September, 1771. Prof. Noyes is of opinion that his health had greatly improved at the last, for in a letter written a month before his death he talks lightly of undertaking an arduous journey and of wanting the "best part of a Barrel" of wine for a dinner party. This, however, may have been an instance of the false eupepsia of the phthisic.

THE LANCET.

LONDON: SATURDAY, NOVEMBER 20, 1926.

THE MINERAL ELEMENTS IN NUTRITION.

In a recent Chadwick lecture Sir ROBERT GREIG reviewed the present state of scientific investigation into problems of animal nutrition. As chairman of the Board of Agriculture for Scotland, he is in close touch with the work which is being done at research centres there, and he evidently has also a wide knowledge of similar work in other countries. His lecture may come to many as a revelation both as regards the prevalence of deficiency diseases, in the sense of mineral deficiency as Sir ROBERT GREIG chiefly uses the term, and as regards the amount of information already accumulated of the causes of these diseases in animals and the means of preventing them. It appears that not only artificial diets used in modern intensive farm practice, but also natural pastures are often of a composition altogether unsuited to support the demands of growing animals, or the drain of lactation, on account of insufficiency of calcium, phosphorus, or some other inorganic element. Experiments at the Rowett Research Institute, summarised by Dr. J. B. ORR in a presidential address to a section of the British Association in 1925, show that the addition of lime to the food of pigs on a diet deficient in this element may double the gain in weight in a given time, and similar experiments by Sir ARNOLD THEILER in South Africa make it clear that the feeding of small amounts of bone meal to cattle grazing in an area where phosphorus is deficient in the pastures will treble the gain in weight. Elements other than calcium and phosphorus may also be deficient. Thus, young pigs seem liable to suffer from deficiency of iron, and deficiency of iodine appears to be accountable for several different pathological conditions in addition to goitre. In short, as regards farm animals, artificial dietaries are likely to be deficient in one or more inorganic elements, particularly calcium, and there are large areas of the Empire where the natural pastures are so deficient in certain inorganic elements that they cannot support in health the animals grazing on them. These data support THEILER in his view that, at least in respect of farm animals, mineral deficiencies are of much greater practical importance than vitamin deficiencies.

How does the matter stand with regard to human dietetics? It is a striking fact that we have no very definite idea of the amounts of calcium, phosphorus, iron, or iodine that are required by a growing child or a nursing mother, or of the amounts that are supplied by different human dietaries. Sir ROBERT GREIG points to the increased consumption of cheap carbohydrate foods and highly-refined foodstuffs. Dietaries including large proportions of these foods and little milk or vegetables should presumably be placed in the same category as artificial farm rations, for they are deficient in calcium and possibly other minerals. It seems probable that malnutrition in children may arise from this cause. In the poorer classes, whose children are most likely to be fed chiefly on such foods, both stunted growth and rickets are common. Without dogmatising on the relative parts played in the causation of rickets by hygienic conditions, lack of vitamins, lack of sunshine and lack of lime, it is fair to point out that a condition resembling rickets can be produced or avoided in farm animals by altering the proportion of minerals in the food, and that the Rowett Research Institute has shown the effect of sunshine in healing rickets to be bound up with its effect in increasing the absorption and utilisation of the calcium in the food. As Sir ROBERT GREIG says, milk is a perfect food. But many children are fed, not on human milk, but on cow's milk; and cow's milk, compared with human milk, contains more calcium, but less iron. Further, it is often supplemented from an early age with highly-refined cereal products containing little or no iron. Is it not possible that one of the causes of anæmic conditions in infants may be an actual shortage of iron in the food? The question of whether goitre is due to deficiency of iodine is by no means settled, but the results, as far as they go, on domestic animals and human beings, are in general agreement and seem to point to a possible iodine deficiency in certain areas. It is pretty certain that the danger of mineral deficiency in the diet is less in the case of human beings than in the case of farm animals, but there is undoubtedly much malnutrition suggestive of qualitative errors of diet. The resemblance between these conditions and the conditions arising in animals on diets deficient in mineral elements is sufficiently close to suggest that deficiency of minerals may be one of the factors involved. Such deficiencies would be more likely to assume importance under conditions of restricted diet. In war-time the food of an isolated besieged population is more restricted, and therefore more likely to be ill-balanced than normally, and war-time is always associated with ill-health and disease, in particular with malnutrition in children and nursing mothers. RUBNER calculated the inorganic content of the rationed food of the Germans in 1917–18. The daily intake of calcium, phosphorus, and iron was estimated in grammes at 0·226, 1·922 and 0·089 respectively, compared with 1·221, 4·472, and 0·154, the estimated pre-war intake. GREENWALD has suggested plausibly that this change in the inorganic content of the food may have had some influence on the causation of "war œdema." It is possible that in the study of human dietetics too little attention has been paid to the inorganic elements in the food, and that an investigation into this subject would give interesting results.

INCOME-TAX AND EXPENDITURE ON PROFESSIONAL TEXT-BOOKS.

EXPENDITURE upon his professional library is by no means a negligible item in the balance-sheet of the average member of a learned profession. Doctors can share the disappointment of lawyers at a solicitor's recent failure to persuade the income-tax authorities to permit deductions for the wear and tear of his law-books and for the cost of replacing obsolete volumes. There was solid ground for the solicitor's contention. Schedule D of the Income-Tax Act lets the trader make his reasonable deductions in respect of the diminished value of his machinery or plant by reason of wear and tear; it also allows him, in estimating his trading profits or gains, to deduct the expense of replacing obsolete plant or machinery. Last year's Finance Act declared that these concessions enjoyed by the trader should also be enjoyed by the professional man. The solicitor very reasonably argued that his law library was part of his machinery or plant for the purposes of his profession; further, some of it—presumably his text-books on

the law of property—had become obsolete during the past year owing to great changes in the law. The sum at stake was only £8, but the General Commissioners refused to allow the deduction, and they have now been upheld by the High Court. Mr. Justice ROWLATT said not one person in a hundred would claim that the books of reference on his shelves could be called plant or machinery. He agreed that the books used by professional men cost a lot of money, but he found himself obliged to dismiss the solicitor's appeal with costs.

What does "plant or machinery" mean in the case of a surgeon or physician? The motor-car for visiting patients, the surgical instruments and the surgery fittings, even the replacement of broken bottles—these are items for which the practitioner should claim to make annual deductions on the score of wear and tear, due regard being had to necessity rather than luxury, and to professional rather than private and personal use. No great number of legal decisions enlightens the interpretation of "plant or machinery" in this connexion, nor is the acute and experienced mind of Mr. Justice ROWLATT dependent upon decided cases in revenue matters. One of his own previous decisions, given in 1915, refused to allow Lord DERBY to deduct annual depreciation on the active lives of two stallions at stud in a racing stable. The life of a horse, said the learned judge, has a normal average length, like that of a tree, in the course of nature; ownership of it is an investment in a naturally wasting security; loss of usefulness due to old age is not wear and tear. In the face of this decision it seems hard if a costermonger cannot deduct for wear and tear to his donkey, or a carrier in respect of his horse, since a ferryman could presumably make deductions in respect of his boat. In extending the concession for wear and tear to professional men, Parliament must have realised that their "plant" would intrinsically differ from that of a butcher, baker, or candlestick-maker. Learned professions need the equipment of learning. The wear and tear of a book is as obvious as that of a boiler-house. Traders are presumably allowed deductions for machinery rendered obsolete by new inventions or by the accessibility of fresh sources of power. Why should not a professional man's professional library be "plant or machinery" for which income-tax deductions can be made when existing treatises are rendered obsolete by the passing of fresh laws or the publication of fresh scientific discoveries? Not long ago it was held that a medical practitioner holding various official appointments was not allowed[1] to deduct for income-tax purposes the cost of annual subscriptions to professional societies, though the expenditure was reasonably necessary for the efficient discharge of his duties.

So stands the law, and now no deductions will be possible in respect of the professional man's library unless the Income-Tax Act is amended.

POLIOMYELITIS IN SCHOOLS.

ACUTE poliomyelitis may occasionally be transmitted by flies or dust, but it is generally agreed that the infection is spread mainly through carriers, and the time is appropriate to summarise the excellent short chapter on this subject in Dr. K. C. PAUL'S little book on "The Carrier Problem."[2] Every case, this section of the book suggests, of poliomyelitis is regarded as developing from one or other type of carrier—contact or convalescent. Contact carriers are responsible for epidemic spread or for conveyance of infection to distant places; in them the carrier state usually does not last longer than three weeks; some of them are incubating and later develop symptoms. Convalescent carriers are generally persons who have had an unrecognised abortive attack, and in them the carrier state may be chronic. A group of 110 cases of acute poliomyelitis in an American community were all infected by a carrier from an infected household in a distant locality. S. FLEXNER was however unable to demonstrate by animal inoculation the long survival of the virus and believes that enduring carriers are of exceptional occurrence. Certain American observers found the virus still viable in the dust of the sick-room in which patients suffering from the disease had been confined; most regard the virus as living in the nasopharynx and occasionally in the tonsil. Numerically the susceptibility of the members of a community is small; C. HERMANN estimates it at less than 2 per cent., and attributes the defence against infection to local protective action, natural or acquired, on the part of the mucosa and its secretions. Certainly, a substance capable of neutralising the virus has been found in the washings from healthy nasopharyngeal mucosa, and carriers may owe their contamination to the absence of this neutralising substance. The method of transference—whether by direct contact, droplets of infected mucus, or virus-laden dust—is still problematical, for the virus eludes microscopic identification and its recognition requires inoculation into monkeys. In America management of the carrier has been limited to quarantine; the Flexner school regards the application of antiseptics to the nasal mucosa as of doubtful value, and it is not impossible that they may affect unfavourably the destructive properties of the nasal mucosa and to that extent be even objectionable.

One attack of acute poliomyelitis protects against a second, and, as we have recently pointed out,[3] there is reason to suppose that the general immunity of adults and older children in this country has been acquired by exposure to mild infection. In a community where this infection is easily picked up it is probable that most of the children will have met and fought the virus before they are more than 4 or 5 years old, and the disease is therefore unlikely to be dangerous in schools except when it has been uncommon amongst the general population for a long period. These assumptions may explain why school epidemics have been so rare in this country, and their rarity in turn explains why during the last few weeks different authorities have taken opposite views of the problems they present. About the middle of October a number of cases of acute poliomyelitis were reported in Broadstairs and the neighbourhood, many of them in boarding-schools and day-schools. The urgent question arose: Should the children be sent home? On the advice of Lord DAWSON and Dr. JAMES COLLIER it was decided that they should not. Dr. E. G. MOON, of Broadstairs, appealed to a group of schools affected to fall in with a policy of strict isolation, and each of them did its best to cut itself off from the town. The pupils were daily inspected and those who showed the slightest illness were at once removed; general meetings—as for chapel—were made as short as possible; the children were kept a good deal in the open air and they were made to gargle their throats three times a day with weak antiseptic. Informing circulars which we reproduce on page 1085, were sent to the parents, nearly all of whom allowed their children to remain at school, although, of course, they were not asked to agree to this course against their own judgment. The result, in this instance, goes far to justify the bold action taken; during more than a fortnight no fresh case of poliomyelitis has arisen. But it does not in itself show that the totally different action taken last week by the authorities at Uppingham School was an error of judgment. At each place a heavy responsibility was incurred in order to gain certain advantages. At Broadstairs it was claimed that the benefit of supervision and a healthy life outweighed the risk which any particular child ran by remaining at school; but it must be admitted that this was none too certain, and some of the cases which developed after the order to stay was given must be placed on the debit side in casting the accounts of the policy. On the credit side the present generation of Broadstairs

scholars is now reasonably immune from poliomyelitis, and the schools have solved their own problems without endangering the rest of the community. Dr. PAUL, whose views we summarise above, is reasonable in his assertion that any person who has been in contact with an active case of poliomyelitis must be regarded as a carrier, and the only management of a carrier at present is to place him in quarantine for at least three weeks. The responsibility which Uppingham School has taken is to send 500 potential carriers to their homes—where it is to be hoped that they will have been placed under adequate control as a letter to the parents from the headmaster would suggest. In an interesting paper which we publish this week (see p. 1057) Dr. A. I. SIMEY, of Rugby, defends the practice of sending boys home at the end of term, even although they may be in quarantine. "If a boy *has* to be ill," he says, "home is the more appropriate place for him." This view will have its critics. No one would suggest that more than a very few of the Uppingham boys are really carriers, although the two cases occurred in separate houses; but at the same time, from the point of view of public health, the situation cannot now be controlled as it could have been controlled even in the scattered units of the school. At least one of the pupils taken away from Broadstairs has already infected another child in another part of England, and it may happen that carriers from Uppingham—if any—will do the same; which possibility has to be set against the natural satisfaction which the boys' parents must feel at having their sons removed from an immediate danger. Many medical men would undoubtedly take their children away from school in similar circumstances; but undoubtedly the child thus removed should, properly speaking, be isolated as a possible carrier. The frank account of the two cases at Uppingham, furnished by Dr. WILLIAM DUNN, the school medical officer, shows the fulminating nature of the first case and the successful treatment of the second, while pointing out that at Uppingham the isolation policy would have been attended with scant chances of efficacy.

Some of the disadvantages of protecting young school-boys against infectious diseases are spoken of in Dr. SIMEY'S address. They are apt to contract their measles and mumps at a more inconvenient time. We have referred above to the view that immunity in poliomyelitis is chiefly acquired, and, if this is true it furnishes, perhaps, an argument that carriers should roam as they will. It does not, however, furnish a convincing case in favour of allowing the disease to work out its own salvation in a confined community—e.g., a school—because it is possible that an infection becomes more virulent in its passage through such communities. When Uppingham reassembles, as has been pointed out, the risk of infection will still remain, and an efficient means of protection would obviously be useful. In this connexion some apposite results have recently been communicated to the Swedish Medical Society by Dr. H. DAVIDE, whose earlier work on the bacteriology of this disease was already well known. During 1924 there was a series of outbreaks in a Swedish district, where the scattered and comparatively stationary character of the population offered exceptionally good facilities for studying the epidemiology of the disease. Dr. DAVIDE spent a considerable time in making personal, house-to-house investigations, and was able in many cases not only to trace in chronological order the spread of the disease from one person or family unit to another, but also to show that the proportion of slight or abortive forms was very considerable. Having mapped out the areas that were likely soon to be involved in the epidemic, Dr. DAVIDE proceeded to immunise a certain proportion of the juvenile population with the serum of patients convalescent from a typical attack of acute anterior poliomyelitis. The principle followed was that put into practice in the case of measles by NICOLLE and CONSEIL. The serum was taken from the convalescents not less than ten days after they had become afebrile, and the usual steps were taken to ascertain that the serum was sterile and Wassermann negative. Five c.cm. of the serum, to which 0·5 per cent. of carbolic acid had been added, were injected into the muscles in the gluteal region. Only persons under the age of 25 were selected for this experiment, and half the number of the persons under this age were not treated, so that they might serve as controls. Dr. DAVIDE must have experienced difficulty in finding controls, and he admitted that while it was easy to interest parents in the inoculation of their children, it was much harder to explain why only every other child was to be treated—such are the conflicts between science, as defined by the seeker after knowledge, and humanity, as defined by the parent. Dr. DAVIDE succeeded, nevertheless, in studying 157 persons under the age of 25 in a threatened district. Of these he inoculated 73 and left 84 to serve as controls. Of these 84 as many as 14 subsequently developed abortive or typical acute anterior poliomyelitis, whereas among the 73 who were inoculated only one fell ill. This was a boy, 4 years old, who developed definite cervical rigidity within 40 hours of the injection. The child was probably febrile, but the temperature was not taken. The malaise lasted only half a day, and it seems likely that the child was caught in the incubation period and that the inoculation made the disease run a mild course. Among the 14 controls who developed the disease, the majority showed only the abortive forms, but there were several cases in which definite paralyses developed. As Dr. DAVIDE pointed out, his material is too small to justify final conclusions; but it certainly warrants further investigations on the same lines. The immunity conferred in the manner indicated may not last more than a few months, but in the meantime an epidemic may have blown over, and the dangerous time of the year, August and September, during which most paralyses and deaths occur, may have been safely tided over. The supply of suitable serum is, of course, bound to be limited, but the chances of its doing any harm are very small. For, as Dr. DAVIDE insisted, serum taken from a convalescent at least 10 days after he has become afebrile, is not at all likely to contain the virus of acute anterior poliomyelitis, which has not hitherto been conveyed from one experimental animal to an another by blood infection.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION.—On Thursday, Nov. 25th, at 5 P.M., Mr. Harold Chapple will lecture at the Medical Society, 11, Chandos-street, Cavendish-square, London, W. 1, on the Emergencies of Pregnancy and Parturition. On Tuesday, Nov. 23rd, at 11 A.M., Mr. B. Leggett will give a lecture-demonstration, at St. Mark's Hospital, on Radiological Investigation of the Colon and Rectum. Both these lectures will be free to members of the medical profession. A week's comprehensive course will be given at St. Mark's Hospital, from Nov. 22nd, instruction being by operation, demonstration, and lecture. A late afternoon course (5 P.M.), from Nov. 22nd to Dec. 18th, will be held at the West End Hospital for Nervous Diseases, 73, Welbeck-street, London, including lectures and demonstrations upon selected cases; the fee is one guinea. For the convenience of general practitioners the London Temperance Hospital will hold a course in medicine, surgery, and the specialties from Nov. 29th to Dec. 11th (4.30 to 6 P.M.). Courses in obstetrics can now be arranged for at the Queen Charlotte's Hospital and the City of London Maternity Hospital. The Fellowship has concluded arrangements with the Samaritan Hospital for Women to provide clinical assistants; personal application should be made to the Fellowship. Practical courses in anæsthetics can also be provided. Copies of all syllabuses, of the General Course Programme, and of the *Post-Graduate Medical Journal* may be had from the Secretary of the Fellowship at 1, Wimpole-street, London, W. 1.

Annotations.

"Ne quid nimis."

THE ADJUSTMENT OF ARTIFICIAL LIMBS.

THE circumstances attending the fitting of a patient with an artificial limb have been discussed on more than one occasion, accompanied with the suggestion that regular coöperation between the surgeon and the instrument-maker to obtain the best results from their joint work is not sufficiently insisted upon. A case in point has been brought before us this week. The patient had the leg amputated below the knee for a chronic tuberculous condition, when the instrument-maker found that, owing to the conformation of the stump, great difficulty was experienced in fitting an artificial limb, and in the end the particular prosthetic appliance was heavy, while as it happened the firm in question, Desoutter Bros., have introduced artificial limbs of unusual lightness. The heaviness of the appliance was not obviated by many modifications and adjustments made by the instrument-maker, whose adaptations so far as measurements was concerned often appeared trivial, but were of importance if a successful result was to be obtained. The opinion of the instrument-maker on the whole situation is not new, but it is none the less important. It is that it should be a routine for the "surgeon about to perform an amputation to take counsel with the artificial limb-maker in order that the precise site of the operation, flaps, and other details might be so devised as to make an artificial limb of the greatest possible service and comfort to the patient." These words he qualifies by the admission that he is not talking about urgent cases, but his strong opinion is that in the individual case, which led him to communicate with us, a slight change in the shape of the stump would have allowed the patient to be fitted with a lighter appliance, and would have spared a great deal of the time and trouble expended on modifications of the artificial limb in the course of the fittings. As it is certain that artificial limb-making can never be a matter of mass production, every appliance depending for its perfect fit upon individual and variable factors, there is much to be said for the instrument-maker's point of view—so much indeed that some surgeons always call the instrument-maker to their assistance prior to operation. "Amputation both in civil and military practice, equally on account of disease or injury, have to be performed to save the patient's life or, at least, to cut short an exhausting disease or to rid the body of a useless segment. These are the primary objects of amputations. The secondary object of an amputation is to provide a stump most useful and suitable for the attachment and use of a prosthetic appliance." This quotation from Mr. Muirhead Little's recent book, "Artificial Limbs and Amputation Stumps," indicates the necessity for coöperation between the surgeon and the artificial limb-maker. It is necessary for an artificial limb to be accurately fitted to the amputation stump. It is also advisable that the amputation stump shall be fitted for the reception of the artificial limb. It is still too often found when an amputation has been completed and the stump has soundly healed that it is not the best that could have been devised from the point of view of the prosthetic appliance. All surgeons must be prepared to carry out amputations, but all surgeons do not study the mechanism and fitting of artificial limbs, and all are therefore not familiar with the problems of the limb-maker. As a result of war surgery and of the segregation in hospitals such as Roehampton House of large numbers of patients who had suffered amputation, a great deal has been learnt about the best methods of performing amputations in order to render the stumps useful and to adapt them to the fitting of modern types of artificial limbs.

Observations derived from this experience are incorporated in such works as that of Mr. Muirhead Little and in Sir Robert Jones's "Orthopædic Surgery of Injuries," and it seems probable that this teaching has not received sufficient attention from the surgical profession, for complaints still frequently arise that the limb-maker, being unable to fit a stump in a satisfactory way, has expressed the wish that the amputation had been performed differently. It is not difficult to quote instances. Amputations through the tarsus (Charcot's amputation) are in many cases very difficult or indeed impossible to fit, and modern surgery condemns this method of amputation as being far less useful than a Syme's amputation. Amputations below the middle of the leg are equally awkward; the long stump gives no additional advantage in leverage, but it occupies a large section of the bucket of the artificial limb and necessitates the whole of the leg-piece being made thicker than is necessary, so that the limb is not symmetrical with its fellow. In addition, it is found that this long leg amputation leaves a stump in which the circulation in the terminal part is almost invariably bad. Amputations through the knee-joint and immediately above it are extremely awkward to fit, necessitating a heavy and cumbersome limb without giving any compensating advantages, unless in very exceptional cases, and in amputations through the hip-joint, if a bucket is to be comfortably fitted, the flaps must be kept sufficiently short to leave a firm and rounded stump, the flabby, loose stump resulting from the Furneaux-Jordan amputation being extremely difficult to fit.

It is most unsatisfactory for the patient if, after an amputation has been performed and the stump is soundly healed, he has to be told that some further operative treatment will be required before the limb can be satisfactorily fitted. It would appear to be reasonable that in all cases where the surgeon is not used to the fitting of artificial limbs and where he has to perform an amputation which is not a matter of urgency he should consult with the limb-maker in advance and possibly modify his methods somewhat in order that the stump resulting may be one to which an artificial limb can be comfortably fitted. Of course, the primary factors to be considered in fixing the level of amputation are the disease or injury for which the operation is being performed and the necessity for removing this adequately, but the level so fixed may be modified as the result of a consultation with the limb-maker and the method of cutting flaps, &c., may also be adapted with this end in view.

SOCIAL CAPACITY.

GOOD behaviour under close supervision in an institution may be nothing more than passive compliance with routine and affords no guarantee of social adaptability to the conditions of ordinary life. This is emphasised by Dr. R. F. Jarrett in an article which appears on p. 1059, and it is a point too frequently overlooked or at least imperfectly realised in connexion not only with the insane and the defective but also with the criminal, when the question of release is under consideration. Outside environment requires to be carefully selected in conformity with the mental qualities of the released prisoner, for, as Dr. Jarrett points out, while criminality in any individual case may be explained by the play of circumstances upon the personality, that personality, that inherent mental constitution upon which they play, is as important as, or perhaps more important than, the circumstances. It therefore becomes a matter of much significance to discover by some means what the individual's possible capacity for social adaptation is, and to this end many experimenters have suggested tests of various types. Among others Dr. S. D. Porteus, of the Vineland Training School, New Jersey, claims for his now well-known "maze" tests special value in this direction. Dr. Jarrett has applied these tests to 100 Borstal lads at the end of two years' training. The results he quotes would have been more valuable if he could have demonstrated the correlation of these results

with the actual social behaviour of the lads in after-life (for which he would, of course, have to wait a few years) or even with their social traits as revealed during their institution life. Dr. Porteus himself devised a social rating scale, in which certain mental qualities—planning capacity, executive ability, suggestibility, impulsiveness, excitability, irresolution, moodiness—were assessed by expert observers, and found a fairly high correlation to exist in persons of 20 to 30 years of age between these estimates and the maze tests results, much higher than that given by the Stanford tests. Observations of this or of an analogous type carried out on a fairly large scale are indispensable before reliance can be placed upon the maze tests as a social indicator. Some English observers are disposed to think that the qualities of foresight and planning capacity revealed by these tests are very superficial, and give but a poor index of the foresight required in daily life. Others have found some relation between the results and practical manual capacity in children. The qualities of intelligence lend themselves fairly readily to testing methods, but the temperamental qualities are elusive and not only may make a man's "actions" inconsistent with his "words," but also make his action at any one moment, which may be a moment of crisis, utterly inconsistent with all his previously known character. Adequate tests of a man's moral reactions are not yet forthcoming, and it does not appear to be the case that the Porteus maze tests are of great help in this direction, except in so far as they reveal impulsiveness and excitability of temperament.

THE SELECTION OF MEDICAL STUDENTS.

THE Argentine medical schools, and especially the one at Buenos Aires, are suffering from a plethora of students. Writing in the *Semana Medica* (Sept. 16th) Prof. B. A. Houssay voices the opinion of the majority of the teachers, when he says that the number of candidates for medical degrees ought to be limited by a previous inquiry into their physical, intellectual, and moral qualifications for the study of medicine. The Argentine, with a population of 11,000,000, in 1925 had 5800 students, whereas the United States, with a population ten times greater, had only 18,200. The number, moreover, is steadily increasing. In 1910 there were 2150, but in 1926 6960 students. Of the 700 or so who enter yearly at Buenos Aires, not much more than a quarter qualify, the remainder dropping out at various stages of their career. Hence the troubles of overcrowding are felt especially by teachers of the preliminary sciences, whose laboratory and class-room accommodation are quite inadequate and who are overworked in the attempt to give instruction, much of which is thrown away. Such a state of affairs cannot be in the best interests of the community or the medical profession, for an excess of students implies inferior training for those who will ultimately qualify. As for those who give up the struggle, they have spent a year or two in idleness or in work which may be of little value to them afterwards and have deferred their settlement in life—though the educational value of elementary medical training is, of course, considerable. And apart from these considerations a good deal of public money is often used up in the instruction of those who fail to qualify. Granted that limitation is needed, the method presents difficulties. Probably Prof. Houssay's suggestion that before entry there should be courses of study under the supervision of the Faculty of Medicine is as good as any. Properly devised and carried out, they should ensure that mere ability to get through examinations is not the only test of suitability for medicine, and that the student who is apt in scientific work is not excluded owing to failure in the ordinary curriculum. The method of *oposicion* (or disputation) recommended by Prof. Houssay in default of preliminary courses is probably unsuited to Anglo-Saxon, though in favour in Latin countries. To keep out mere wastrels some certificate of character may well be required from the school authorities, as it is hardly possible for a board of selection to arrive at an estimate of moral qualifications in a few minutes' interview. It should be noticed that all the best medical schools in the United States limit their numbers, presumably in proportion to the capacity of their class-rooms and laboratories, and this is only reasonable. Similarly, our English medical schools exercise a certain amount of judgment. Any early selection puts a heavy responsibility on the authorities, and there will always be cases of individual hardship, whatever method is adopted. The student whose mental development is somewhat retarded, or who has little aptitude for competitive work, may have the makings of an excellent doctor and will possibly suffer under a selective system; but he already suffers under examinations, and it cannot be to anyone's advantage to have an overstocked profession whose education has been marred by the inadequacy of the means of teaching. An excess of doctors is apt to lead to such stress of circumstances that dubious methods of making a competence are adopted, and whatever the advantages of a free system the fact must be faced that owing to the spread of higher education the number of aspirants to the medical profession is likely to increase rather than diminish.

THE NEW R.S.M. PROCEEDINGS.

THE new Editorial Committee of the Royal Society of Medicine has not been long in getting under way. This Committee consists of the President, Hon. Treasurers, and Hon. Secretaries of the Society, along with a representative of each of the 24 Sections. The Hon. Editors of the *Proceedings* are Sir William Hale-White and Dr. T. Watts Eden, and the first fascicle of the 20th volume, dated November, 1926, which reached us on Nov. 12th, contains reports of Sections which met so recently as the 8th, 14th, 15th, 20th, 21st, and 22nd of the previous month. The format of the *Proceedings* has always been agreeable and the illustrations excellent, but the new series has taken on a more orderly appearance in having a continuous pagination at the extreme head of the page for the sake of indexing and reference, and a secondary pagination for the members of the particular Section who may wish to bind separately the part of the Society's work in which they are specially interested. Author and title of paper also appear at the head of each page. All these changes, so desirable in themselves, and likely greatly to increase the usefulness of the Society to Fellows and Members unable to attend meetings with regularity, take the sting out of an article by Mr. Charles Frankenberger, Librarian of the Medical Society of the County of Kings, Brooklyn, a reprint of which has just reached us[1]. Mr. Frankenberger writes frankly of the troubles of medical librarians, finding most to criticise in the medical periodicals which, he says, comprise two-thirds of the collections of the larger libraries. His greatest grievance is in the matter of page numbering. The ideal is, from a book-making as well as from a library standpoint, one set of page-numbering of all text-matter comprising a volume, and, in the breaking of this rule, he finds the Royal Society of Medicine to have been the greatest offender with its "twenty-five separate sets of paging," now happily at an end. The title of a medical periodical should, says Mr. Frankenbeger, be short, and here, as on the previous heading, THE LANCET may take some unction to its soul, in contrast to Mr. Frankenberger's examples of titles such as *Archives des maladies de l'appareil digestif et des maladies de la nutrition*, and *Berichte über die gesamte Gynäkologie und Geburtshülfe sowie deren Grenzgebiete*. Other points on which this medical librarian sets value are that volumes should begin and end with a calendar year and that Roman numerals should be discontinued in bibliographies, indexes and reference work. He is annoyed at journals which cease publication without giving

[1] Reprinted from the Journal of the American Medical Association, August 21st, 1926.

notice of the fact and with others which change their title, or subdivide it into parts under other titles. And finally he pleads for standardisation in size, for his library shelves have to adapt themselves to the *Denver Medical Bulletin*, with its pages a trifle larger than a postal card, and to the *Voz Medica* of Madrid, which appears in newspaper form, 18 by 24 inches. We are glad that London medical publications are giving him but little cause for trouble.

ULTRA-VIOLET THERAPY IN A GENERAL HOSPITAL.

THE value and limitations of ultra-violet therapy can be assessed more truly from the statistics of big hospitals than from the results of personal experience. An article by Dr. A. C. Roxburgh in the November issue of *St. Bartholomew's Hospital Journal* deals briefly with the results of treatment during the past 21 months of 272 patients, exemplifying 56 different maladies. A complete list of the cases and details of their progress is given and the conclusions drawn are convincingly temperate. It is interesting to note that, in the treatment of lupus vulgaris, purely general treatment, while giving good results, is not considered to eliminate the necessity of local applications. Tuberculous peritonitis did not respond, more than half the patients being worse, or at any rate no better, after radiation. Many conditions responded in a variable manner, for the patient is the most variable factor in the treatment. It would be interesting to compare the results at St. Bartholomew's with those of other great hospitals, and we may hope that such statistics will be forthcoming.

LAUGHTER AND TEARS.[1]

Lord Knutsford's autobiography is a happy and successful man's informal record of what he has done and the environments therewith; it is the life of a social aristocrat, blended with that of an enthusiastic philanthropist and a capable business man. The book is full of good stories concerning kings and cabinet ministers, scholars and sportsmen, nurses and game-keepers, lowly people and social outlaws. There are passages, never elaborated and never gushing, recording the writer's intimate experiences among the suffering poor; they are moving to tears, but their appeal is accentuated by an instinctive determination to avoid what the Americans have taught us to call "sob stuff": the poignancy of these revelations is due to the simplicity of the telling. As we read we can see clearly that throughout his life Lord Knutsford has played many parts successfully exactly because in a sense he never *played* them, but *was* them; he was always himself, and realising the great chances which birth, brains, and temperament had given him for being thoroughly happy himself, he determined to use these chances in contributing to the happiness of others.

All interested in the management of large charities, and especially in hospital work, should read the book with its intimate account of the London Hospital. Mr. E. W. Morris's history of that institution may be well known to many of our readers, but Lord Knutsford's reminiscences make an admirable pendant to the work of the secretary of the institution. When, 30 years ago, Lord Knutsford was asked to take the chairmanship, the buildings, he says, were old and in bad repair, there was but one operating theatre for the 650 beds, one tiny room sufficed for all the bacteriological work of the hospital, there were no pathologists and no clinical laboratories, biochemistry was not thought of, and the accommodation for the nurses was disgraceful.

Many of these words could have been written about a majority of the other general hospitals, but the distinguished staff of the London Hospital at that date do seem to have been performing work which made the hospital famous in circumstances of unusual difficulty. Modestly, and dwelling rather upon instances of successful mendicity than of drastic material changes, Lord Knutsford describes the reorganisation, rebuilding, and refinancing of the hospital, giving in every direction full credit to devoted house committees, and to generous friends inside and outside the institution. It is a record of charitable work for which alone the volume was worth writing.

A fascinating book.

THE VIENNA ANTITOXIN CONTROVERSY.

THE unfortunate accident which occurred[1] at Baden, Vienna, in October, 1924, when six children died after the injection of a mixture intended to produce active immunisation against diphtheria, is still the subject of controversy. The two sides to the dispute are taken by Grassberger[2], who was legally appointed as expert to investigate the matter and to examine the available stock of the incriminated batch of prophylactic, and by Busson[3 4], who with Loewenstein was apparently responsible for the making of the material. Grassberger, who made an exhaustive examination of all material available, concluded that the phials could be divided into two groups, one filled with material completely atoxic to animals, the other filled in error with toxin highly toxic to animals, and, unfortunately, to children. His conclusions were based on three lines of evidence. The children who were ill, and those who died, presented symptoms suggesting that they had all received approximately the same dose of toxin. Secondly, one group of phials contained material completely atoxic in guinea-pig tests, the other group material of uniform specific toxicity. In the third place, no antitoxin could be found in the toxic phials either by direct chemical test, nitrogen determination, or by tests based on the Dale anaphylactic-uterus method. Grassberger further tried by chemical and physical processes to make the atoxic toxin-antitoxin mixture toxic, but failed.

Busson bases his reply on the supposition that all the phials contained atoxic mixture when issued, but that owing to the influence of heat or cold or other agent during storage, the mixture had dissociated so that the toxin was released, and the mixture became highly toxic. He replies to all of the lines of evidence: the course of the disease was different in different children, and, therefore, the ampoules must have contained different quantities of toxin; there were fallacies in the guinea-pig test made during the official investigation, and the tests applied for the presence of serum were fallacious. He further states that Grassberger's own experiments show that an increase of toxicity can be obtained by the use of acids, alkalis, and freezing, and finally that an erroneous replacing of a bottle of mixture by a bottle of toxin cannot possibly have happened during the filling. Unfortunately, the controversy had reached the stage where an accusation of falsification of the laboratory note-books has been made and denied. We do not know if any further legal proceedings in Austria are in prospect.

Should Grassberger's hypothesis be adopted—and many immunologists seem inclined to adopt it—an important aspect of the matter must not be overlooked. The public cannot demand of any human being that he shall never make a mistake. We do not imprison a railway director every time a collision occurs, but we are justified in demanding of the responsible members of a serum institute not only a reasonable degree of skill, but a very high degree of vigilance in their work. Was this lacking at the institute in question? As regards such institutes in general, since the discovery of diphtheria antitoxin many millions of doses of material for injection into

[1] THE LANCET, 1924, ii., 1079, 1086.

[4] Med. Klinik., 1926, xlii., 1626.

human beings must have been issued, and accidents due to contaminated or faulty materials have been almost unknown. We can, therefore, feel fairly confident that the work is well and faithfully done. So far as prophylaxis against diphtheria is concerned, there is probably more skill and care required in its production than in any other material of the kind used by the physician. In this country mixtures containing toxin and antitoxin have found little favour with the practitioner; he has preferred to use injections, which contain not unaltered toxin, but harmless toxoid and some small amount of antitoxin. Such prophylactics appear to be equally efficient as immunising agents; and they have the great advantage of being safe, even if dissociation should occur as a result of exposure to extreme cold or to the action of any other physical or chemical agent.

MERCURY IN LATE SYPHILIS.

A REPORT[1] on the Effect of Treatment on the Wassermann Reactions of Syphilitic Patients, with special reference to the failure of mercury to prevent Wassermann relapses, has just been published by Prof. E. E. Glynn, Dr. R. E. Roberts, and Dr. Phœbe Bigland. The investigations recorded concerned over 700 cases treated at the Liverpool Royal Infirmary Venereal Clinic between 1918 and 1923. The main lesson to be drawn from this careful study, besides confirmation of the vital importance of immediate and thorough treatment of early cases, is that though mercury is usually efficacious in removing the clinical manifestations of syphilis, it is unjustifiable as a routine to treat a Wassermann-negative syphilitic with mercury alone with a view to the prevention of clinical or Wassermann relapses, or to the cure of the disease by the destruction of any residual spirochætes. In the authors' opinion a Wassermann relapse signifies renewed spirochætal activity, and, therefore, injury to the patient, though they admit that this is sometimes only potential. They conclude from their investigations that while mercury tablet courses certainly do not diminish the tendency to Wassermann relapse, grey oil courses definitely increase this tendency. It is not clear by what mechanism grey oil increases the tendency to relapse, but Prof. Glynn and his co-workers believe that the mercury, unable to attack the inaccessible residual spirochætes, depresses the patient's general health and the immunity on which the destruction of spirochætes chiefly depends. Since arsenobenzol preparations are more potent spirochæticides than is mercury, and since, moreover, they believe that resistant strains of spirochætes are probably developed by prolonged administration of the latter but not of the former, they recommend extra courses of salvarsan rather than mercury for the prevention of Wassermann relapses and the destruction of residual spirochætes. It will be noted by readers that the investigation covered the period 1918 to 1923, when the value of bismuth as an adjuvant in continuation treatment was not yet appreciated. In an italicised footnote to their conclusions the authors make it clear that their criticisms as to the value of mercury refer only to its administration in Wassermann-negative, latent or quiescent syphilis. They state here that its value in clinically active or Wassermann-positive syphilis is not questioned by them, though elsewhere (page 63) it is noted that in clinically active syphilis mercury alone rarely reduces the positive Wassermann to negative. The conclusions reached as to the failure of mercury continuation treatment coincide with those published by P. Fildes and R. J. G. Parnell in 1919—one year after the present investigation was started and four years before its completion—in the same series of Medical Research Council Reports. Of the work of Fildes and Parnell the authors were, surprisingly enough, unaware until their own conclusions were established. Throughout the report it is clear that the clinical importance attached to the Wassermann reaction by the Liverpool workers is very great. They admit that certain authorities regard a relapse to a positive Wassermann in late syphilis as not of necessity signifying spirochætal activity, but since even in the absence of clinical evidence the reaction is regarded as a reliable pathognomonic sign in early cases, they hold this attitude to be illogical, and maintain that the onus falls upon the sceptics to demonstrate at what period of the disease the Wassermann substance mysteriously changes its character and, therefore, its significance. Prof. Glynn and his colleagues themselves state in their introduction that "it will, of course, be realised that this is a study of syphilis at a venereal clinic, not at a neurological clinic, where the diagnostic value of the serum Wassermann is less, as in locomotor ataxia, &c." It seems that even they admit that there is a late stage in the history of syphilitic infection where the clinical significance of the Wassermann reaction becomes less important. Whether this stage is reached comparatively early or very late, the fact now seems to be definitely established that routine inunction of grey oil or the administration of mercury in tablets is not advisable when the disease is no longer active. This is a useful lesson, since the prolonged administration of a recognised cumulative poison is obviously undesirable unless a definite therapeutic result is to be anticipated.

MEDICAL FEES IN KENT.

THE Kent Panel Committee has been inquiring into the average fee charged by practitioners in that county to patients of economic position similar to that of insured persons. Of 692 forms sent out 458 were returned and the return was more complete than these figures suggest, since it was rare to receive more than one form from a partnership. Of the 458 only 321 were of use for the inquiry, the remainder having reference to practitioners in public services and institutions, or others who were no longer in general practice. The figures given in the table are based on 321 forms and are believed to represent the average position of some 450 general practitioners. The total number on the panel in Kent is 520. The forms were classified according to the density and type of population into four groups:—

(*a*) Industrial areas, such as Chatham, Gillingham, and south-east London.
(*b*) Urban residential areas—i.e., suburbs of the type of Bromley.
(*c*) Semi-rural areas—i.e., country towns and seaside resorts.
(*d*) Rural areas remote from towns.

The figures in the table between parentheses show the number of returns averaged in each case. The average fee is in every case a fraction of a penny below the actual finding, and where any fee was stated as ranging between two figures, the lower figure was taken in striking an average. The average number on the panels in each group was (*a*) 1303, (*b*) 666, (*c*) 847, and (*d*) 688.

Charge for—	Area (*a*).	Area (*b*).	Area (*c*).	Area (*d*).	All areas.
	s. d.	*s. d.*	*s. d.*	*s. d.*	*s. d.*
Consultation at surgery	2 9 (50)	3 5 (75)	3 0 (56)	2 10 (50)	3 0 (313)
Consultation with medicine	2 11 (51)	3 6 (61)	3 3 (49)	3 3 (50)	3 2 (287)
Medicine only	2 4 (49)	2 2 (55)	2 5 (46)	2 4 (50)	2 3 (273)
Visit (mileage extra)	3 7 (52)	4 1 (77)	4 0 (56)	4 0 (50)	3 10 (317)
Visit with medicine	3 11 (51)	4 2 (59)	4 4 (50)	4 6 (49)	4 2 (284)
Normal confinement	53 0 (46)	61 6 (73)	51 0 (53)	45 6 (48)	53 6 (299)

It will be seen that the charge for a confinement is 8*s.* below the average in the rural areas, which are

precisely those in which midwifery is most burdensome. Apparently the rural practitioner with a practice (as judged by his panel) half the size of those in industrial areas has but little advantage in other fees.

MILK AND TUBERCULOSIS.

THE relation between milk and tuberculosis, and the means by which the public should be guarded against the risk of tuberculous milk were touched on by a number of speakers at the National Milk Conference held at King George's Hall, Great Russell-street, on Tuesday of the present week. Mr. Wilfred Buckley, speaking from the chair, said that investigations into a large number of samples of milk, taken in various parts of England and Wales, show about 6·5 per cent. infected with tubercle. This does not mean that anything like 6·5 per cent. of cows are tuberculous, since the milk from one cow in a herd may contaminate a large quantity of otherwise uninfected milk. Dr. Harriette Chick spoke of the serious menace to the health of the community through the infection of children by drinking tuberculous milk. Koch's dictum that the proportion of human tuberculosis caused by the bovine type of the bacillus might be regarded as negligible is now, she said, completely discounted, and the present efforts at securing a safer milk-supply consist largely in attempting to remove the danger of tuberculosis among children. Dr. Nathan Raw, regarding it impracticable to eliminate all tuberculous cows, recommended the immunisation of calves immediately after birth, thus preventing them from acquiring infection in the stalls. In addition to milk itself, butter, cheese, and ice-cream might all harbour living tubercle bacilli. Dr. W. G. Savage said that some 3000 deaths a year in this country are due to tuberculosis of bovine origin. The argument is sometimes put forward that the loss is balanced by the immunity conferred by drinking milk infected with the tubercle bacillus. This implies the assumption that the bovine type produces a less virulent form of infection than the human bacillus. There is, however, no evidence to support this view; a clinician cannot differentiate between the two forms as manifested in the patient; only the bacteriologist can do so. The question of relative virulence has been confused, Dr. Savage thinks, with the question of mode of entry. If the same dose were given by the same mode of entry, it would be immaterial which type of the bacillus was ingested. To give living tubercle bacillus in uncontrolled doses is a haphazard and hazardous proceeding; if immunity by mouth is to be aimed at, it should be by graded and controlled doses. This point was taken up and emphasised by Mr. Neville Chamberlain in his presidential address at the afternoon session. The analogy with vaccination, he said, is not a fair one. Vaccination is carried on only by experts who know precisely what they are injecting, whereas nobody knows what dose of tubercle bacillus is carried in milk or what else the milk may contain. The remedy agreed on by most speakers was pasteurisation.

BRITISH RED CROSS SOCIETY.—An instructional film, showing the drill employed in applying the Thomas splint, will be shown at the house of the Royal Society of Medicine, at 5 P.M. on Monday, Dec. 13th.

THE LATE DR. G. P. JOHNSON.—The death occurred suddenly, on Nov. 8th, at his house at Barlaston, Stoke-on-Trent, of Gilbert Petgrave Johnson, medical officer of health for the county borough of Stoke-on-Trent. Dr. Johnson, who was 58 years of age, received his medical education at the University of Glasgow, where he graduated M.B., C.M. in 1890 and M.D. in 1894. He took the D.P.H. in 1893, and had been medical officer of health for the Potteries since the federation of the six towns in 1910. For some years before that he was in private practice in Stoke. Before going to Stoke, Dr. Johnson was senior resident medical officer at the City Hospital, Liverpool. A zealous and careful official, he devoted his attention particularly to child welfare, maternity health, and the abatement of smoke. He leaves a widow and two sons.

Modern Technique in Treatment.

A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions.

CXCVIII.—THE PROPHYLACTIC TREATMENT OF PROLAPSE.

IT is not intended here to discuss the nature of prolapse,[1] but rather its causes with a view to prevention; thus all that need be said in introduction is that "prolapse" will be taken in its widest sense as a generic term signifying the descent of the movable part of the pelvic floor and the viscera attached thereto. The chief difficulty in the problem before us lies in there being considerable doubt as to the precise factors responsible for bringing about prolapse, or rather as to their relative importance. That pregnancy and labour are the primary causes is shown by the vast predominance of the condition in childbearing women. Less than 5 per cent. of cases occur in nulliparæ. That prolapse does occur apart from childbearing shows, however, that, as in other forms of hernia, congenital maldevelopment or weakness of the tissues is an element in its causation, and, therefore, an intrinsic lower resilience of the tissues will likewise play a part in determining the effect of childbearing on women. The proportion of all childbearing women affected is a small one, and the problem is rather that of deciding what are the conditions during reproduction that especially predispose to prolapse.

The common idea is that direct trauma in the shape of perineal laceration is the immediate predisposing factor, but this simple explanation will not suffice. It has long been observed that complete perineal lacerations are rarely accompanied by descent. Most of them are, it is true, repaired at once because of the incontinence of fæces that results. But those in the service of a large hospital frequently see cases of complete perineal lacerations that have been neglected for 20 years or more and eventually come for treatment, but without any prolapse whatsoever. My own experience is that it is unusual to find the two together. On the other hand, laxity of the outlet is almost invariably associated with prolapse, whether in parous or nulliparous women. In the latter the descending mass distends the outlet, so that an overstretched outlet is clearly an effect as well as a cause. Probably, however, over-stretching, deep laceration of muscle-fibres, incomplete healing with fibrous union giving rise to gaping of the outlet play a considerable part in allowing of the bulging of the vaginal walls, especially under strain, and thus facilitating the common type of prolapse in which the parts are dragged down from below upwards. The levator ani pillars (pubo-coccygeus and -rectalis) close the outlet, and with their relaxation, from overstretching or other reason, the vaginal walls tend to bulge through between them as the abdominal contents do from separation of the recti muscles. Weakening of the thin muscular sheet (pubo-cervical) supporting the bladder will allow it to sag down with the anterior vaginal wall. Descent of the vaginal vault and uterus is due to injury and incomplete repair in the sheets of unstriped muscle and condensed fibrous tissue running from the vaginal vault and cervix to the pelvic wall. So long as they remain taut descent of the vaginal fornix and uterus will not occur. Prolapse of the posterior vaginal wall with a pouch of rectum is invariably associated with incomplete perineal rupture and adhesion of the posterior vaginal and anterior rectal walls.

In brief, then, it is the weakening of the attachments of the viscera to the pelvic wall that primarily allows descent to occur. A cystocele will arise from relaxation of the levator ani pillars and the pubo-cervical sheet, and once it is formed it will drag on the cervix. If the cervical attachments are loosened the uterus will be retroverted, so that it comes to lie in the vaginal axis, and then be dragged downwards, bringing with it the posterior fornix and posterior vaginal wall. If, however, the cervical attachments hold, the cervix may stretch and allow of descent of the hypertrophied vaginal cervix, but without descent of the uterus. Cystocele and rectocele may be present with the uterus in its normal position.

[1] The Treatment of Prolapse was dealt with in this series by Mr. Beckwith Whitehouse (THE LANCET, 1923, ii., 1313).

The Timing of Delivery by the Forceps.

The most contentious part of the question is raised when the events during labour most prone to cause weakness of the supporting structures are discussed. The start of the trouble is often ascribed by the patient to one definite prolonged or difficult labour, and probably one such will do more damage than many normal labours (e.g., a protracted second stage with instrumental delivery of an unreduced occipito-posterior position). Rapidly succeeding pregnancies and labours not allowing time between them for full recovery of tone in the supporting structures will also contribute to descent of the pelvic floor.

One rule of obstetrics cannot be broken without grave risk of prolapse, and that is the one forbidding extraction by the forceps before complete dilatation of the cervix. Perhaps the point of the rule would be clearer if it were expressed as extraction before the cervix is fully retracted above the head. If not retracted over the head the cervix is drawn down with the head and the more the cervix resists laceration and the more it stretches, the greater the tension on its all-important supporting structures. I have known of several patients in whom the cervix presented at the vulva soon after rising from lying-in after a forceps delivery. In these cases the less common form of prolapse occurs, in which the cervix and vaginal vault descend first, instead of the more common eversion of the vagina from below upwards. One such case I recollect particularly well—that of an elderly primipara whose first and only labour began in the small hours of the morning and was completed by forceps in time to allow her medical attendant to get home to a bath and breakfast.

The " high " forceps delivery, in which the head is dragged quickly through undilated passages, especially predisposes to prolapse by rapid stretching and possibly tearing of the supports of the cervix and vaginal vault. Powerful uterine action in a quick, natural labour may have a similar effect, particularly in those with feeble muscular tone. The much commoner " low " forceps operation has not the same risks as the uterine supports are not affected, and the soft parts down to the outlet have been gradually stretched by the head. Indeed, there is a considerable weight of evidence to indicate that the prolonged stretching by the head delayed on the perineum may weaken the muscles closing the outlet (in the same way as the prolapsing mass in nulliparæ) more than a timely application of the forceps—say after the head has been distending the outlet for two hours without expulsion being effected.

The Avoidance of Infection and Trauma.

Besides tearing and overstretching, superinvolution or defective involution with fibrosis of the supporting structures is generally accepted as a prominent factor in the causing of prolapse.

The most frequent cause of defective involution is infection with incomplete repair of muscle and replacement by fibrous tissue.

The morbidity-rate rises with all internal interference, while the higher up the tract the manipulation extends, the greater will be the trauma attending it. Therefore the first line of defence against prolapse will be the careful supervision of pregnancy. In view of the possibility of infection of the vagina and cervix from coitus during pregnancy, the danger of sexual relations in the last month or six weeks of pregnancy should be pointed out as part of the antenatal advice ; similarly, sexual relations should not be resumed until at least a week after the lochia have ceased to be blood-stained, while abstinence for the period of involution is the ideal.

All complications calling for internal manipulation, especially those high up the tract, should be avoided. Antenatal examination has greatly lessened the number of "high" forceps operations and other difficult labours due to misfits and malpresentations. The more assistance in delivery can be narrowed down to the low forceps operation the less will be the disability due to prolapse. The strongest argument for manual rotation of the head in a persistent occipito-posterior position is that the undue stretching of the outlet involved in delivery with the occiput posterior is thereby avoided. Hence the principle in management is to allow as long a time as possible for rotation to occur before extracting, and, when delivery is called for, to attempt to make the head follow the normal mechanism.

The careful repair of all lacerations and a strict technique to prevent infection are the natural corollary to the foreseeing of possible complications.

The Management of the Puerperium.

The management of the puerperium presents another possible line of prevention. The revolt against strict rest in bed, introducing the early rising vogue, was due to a recognition of the evils of muscular wasting and general sluggishness associated with the old rigid system. The most generally satisfactory middle-course is that of modifying the routine for the individual patient, allowing her to rise to empty the bladder and bowels, encouraging movement in bed, and starting massage and physical exercises (bed gymnastics) so as to lessen physiological sluggishness whilst maintaining full nursing control and rest for the patient and ensuring her relief from other duties.

Bed exercises are valuable—breathing exercises for the abdominal muscles, contracting of the levator ani, by squeezing up as if to hold a motion, in combination with resisted movements of the adductors of the thigh and various leg and body movements. A particularly valuable exercise can be carried out as soon as the lochia become dark in colour and after sound healing of a perineal laceration—it is that of the contraction of the levator ani with the patient on her back, the knees drawn up, the feet flat on the bed, and the pelvis raised so that she is in the Trendelenburg position, thus taking the weight of the abdominal viscera off the pelvic floor. While " squeezing up " she is told to bring the knees together, the nurse or other attendant resisting this movement by holding the knees apart. Contraction of the adductors of the thigh and levator ani are associated movements that when made together bring both strongly into action.

For a couple of days before rising the woman should be made to sit on the edge of her bed for ten minutes or so, morning and evening, doing bending and heel and toe movements, and thus gradually accustoming herself to bear the weight of her body on her lower limbs.[2]

Should any complications be present to make the early adoption of bed gymnastics inadvisable, massage of the abdominal and back muscles and of the limbs may be substituted until the patient's condition permits her to begin active muscular movements. Frequent change of position and abdominal muscular exercises facilitate drainage from the uterus and vagina and so promote healing. These movements entail the discarding of the abdominal binder which should be reserved for special cases and at the most for a day or two after labour. It merely splints the abdominal muscles and lessens their physiological activity.

The Restoration of Muscular Tone.

Some women, especially those of an over-sensitive and introspective type, after resuming their household duties complain of backache and " bearing down "—doubtless due to weakness in the supporting structures —though little can be discovered in explanation of their symptoms. Usually these symptoms are aggravated by fatigue and especially by standing about, but it is difficult to persuade these patients to take the outdoor exercise that is essential to a restoration of their muscular tone. In some of them the uterus may be retroverted and bulky, showing laxity of its supports and subinvolution, or the outlet may be lax and bulge or gape on straining. Replacement of the uterus and a ring pessary for a few weeks with continuance of the exercises will help to give them confidence to take out-door exercise and, so long as the pessary is not worn for more than three months or so, will do no harm.

In conclusion, the points to be emphasised in the prevention of prolapse are first to secure normal function and avoid complications in labour, especially those from malpresentations and misfits, and to prevent infection. Next a rational management of the puerperium, in which the restoration of function in the muscular supporting structures is the chief objective. Finally, on the return of the woman to her ordinary occupations, care should be taken to relieve symptoms indicating weakness of the supporting structures by efforts directed towards improvement of the general physique.

JOHN S. FAIRBAIRN, F.R.C.S. Eng.,
Obstetric Physician, St. Thomas's Hospital.

Special Articles.

MEDICINE AND THE PRESS.

DISCUSSION AT A MEETING OF THE HUNTERIAN SOCIETY.

AT a meeting of the Hunterian Society held on NOV. 15th at the Cutlers Hall, London, E.C., Mr. MORTIMER WOOLF, the President, presided over a large gathering of men and women.

Lord RIDDELL opened a discussion of this subject. He read the warning notice on advertising issued in June, 1923, by the General Medical Council, whose functions he outlined. He then read the manifesto published by the British Medical Association in July, 1925, in which the Association stated its position in relation to the practice of advertising and claimed to have influenced the G.M.C. to issue this warning notice. He deduced from these pronouncements that a doctor who wrote for the press under his own name took his professional life in his hands, and that a word of editorial praise might bring him under the ban of the G.M.C. The action of the G.M.C., a purely judicial body, in issuing a warning notice at the instigation of the B.M.A., without a test case, was he thought, probably illegal. The duty of the Council was to try cases of alleged infamous conduct, not to lay down rules. He was a strong trades-unionist, but could not approve of a trades-union, such as the B.M.A., exercising judicial functions, especially as it did not represent the whole profession. Moreover, the law, as laid down in the Court of Appeal, defined infamous conduct as that which would be reasonably regarded as disgraceful or dishonourable by his professional brethren of good repute and competency, and this conduct did not include the writing of articles to the press, so long as they did not exalt the writer or run down another practitioner. Lord Riddell suggested that, although bulletins served a useful purpose in informing the public of the progress made by an important man suffering from illness, the medical men who signed them might run the risk of being accused of advertising. Again, he asked why it should be improper to write a newspaper article and laudable to write a five-shilling book. It was open to any medical man to write a book, have it well reviewed, and print laudatory excerpts on the front page of THE LANCET where it would be much read by hypochondriacal laymen. Nobody wanted a race of advertising doctors, but he suggested that if medical authors were given absolute freedom the public demand for them would speedily end.

Sir HUMPHRY ROLLESTON expressed his agreement with much of what had been laid down by Sir Thomas Horder at a previous discussion on this subject. It was important to remove the impression shown by comments in the press that the medical profession was obstructive or adverse to health propaganda. Education of the public in the "laws of physiological righteousness" was an essential factor in the campaign against disease. The press was a great educator and its power for good or evil was unrivalled. Some public instruction in preventive medicine should undoubtedly be carried out in the lay press, but the public should be told much about preserving a healthy condition of body and little about the actual details of disease—in fact, only the early symptoms of grave conditions formed really valuable information. There was an essential difference between works on professional subjects and writing in the lay papers for an audience of possible patients. The less healthy people knew about disease the better for them. A periodic overhaul by a doctor would effectually relieve anxiety. The main question on which the lay press and medical opinion differed was whether or not articles in the lay press should be signed by medical men in practice, since the writers were inevitably advertised thereby and probably estranged their silent brethren. Unsigned medical articles were said to be poor copy for the press, but leading articles on other subjects formed and guided opinion. It seemed inconsistent that the press had unanimously condemned Sir Thomas Horder's suggestion of an advisory board of medical authorities who should guarantee the efficiency of the writer of an unsigned article. No doubt certain articles signed by eminent names had done great good, but if everyone were to write the door was opened to self-glorification and advertisement, and how was a line to be drawn? The press naturally wanted news, but what was new was not necessarily true and the public might well be led astray by honest enthusiasts. It was unlikely that the press would consent to publish only articles on general hygiene. On the whole, it was undesirable that men in practice should write signed articles for the lay press.

The idea that an eminent man could do things that a lesser man would not be allowed to do with impunity was widespread, but he had known of no instance that justified this impression; many persons at the top of the tree had been called upon to give account of themselves. Nor had he ever heard of anyone being hauled up for "conduct infamous in a professional respect" on account of a bulletin.

Mr. W. J. EVANS, disclaiming any knowledge of the difference between the G.M.C. and the B.M.A., said that the newspapers, especially the working journalists, had a distinct grievance; the journalists had been blacklegged as long as he could remember by members of all other professions, who demanded much more for their articles than the journalists obtained. The newspaper was the playground of the journalist and he was the only man who had the right to write therein. He would say for the doctors that they did usually write their own articles when they signed them. Not a newspaper in the world would be likely to publish an article on a "new cure" because no member of the profession would tell them anything about it. It was this extreme unwillingness to tell the facts that was responsible for half the trouble between the medical profession and the newspapers. He did not see what harm there could be in signed articles telling people what they all knew before. Medical news was at one moment a boom and after a boom came a slump; if medical journalism ceased for three months there would be no more demand for it. He suggested that the unfortunate word "advertisement" should be changed to "propaganda." The only possible harm followed articles which extended to regions where there was no fair measure of agreement, while much of the distrust of medical men arose from the fact that they so rarely said the same things.

Dr. E. GRAHAM LITTLE said that it was the intrinsic worthlessness of these contributions to the lay press that was troubling the medical profession; the difficulties of contributing information worth giving were almost insuperable. How far it was possible to convey serious information through the lay press should be the subject of consideration; he did not think that the columns of the lay press were the best place; even if the press would accept such serious articles the public would not believe them. Reports in the lay press usually extracted the frivolous part of a lecture and ignored its real purpose. The medical papers might be used, at least initially, for the exposition of medical advice to the public. It would be to the advantage of medical writers to learn to express themselves simply and to have the wise censorship of a trained staff of medical journalists. The committee of lay and medical representatives proposed by Sir Thomas Horder as a board of reference would be too cumbrous. There was more serious danger than was realised in giving premature publication to unsubstantiated scientific knowledge, and medical communications might come to be offered first of all to lay papers instead of being submitted to the cross-fire of medical criticism. Payment by results should not be applied to research work and the workers

themselves would much rather confirm their work before publication. The less reputable organs of the press were apt to regard medical subjects as so many opportunities for stunts. Another disadvantage of articles in the lay press was the focusing of individual readers on their own symptoms leading to a huge consumption of patent medicines. A healthy instinct was, he thought, a much better guide to such things as diet than any amount of advice in the papers.

Dr. J. M. BULLOCH expressed the opinion that if a medical man really wished to advertise, neither the B.M.A. nor the G.M.C. nor any number of associations would stop him. The name of a persistent contributor to small specialised journals was bound to filter through the "liaison journals"—as he termed THE LANCET and the *British Medical Journal*—to the daily press. The question of medical advertising in the press had arisen with the change that had taken place in the attitude of newspapers during the last 40 years. Whereas a paper used to be the servant of the public and news, now it printed news to support its own views, when it was interesting, and it might be impossible to stop papers dealing with a subject as interesting to the public as medicine. A paper could not afford to retain even medical students on its staff and had to try to deal with individual experts. It had once been considered indecent for a man or woman to mention personal ill-health, but now the subject was frankly discussed, and the present publicity given to illness was not the fault of the papers, which were meeting a public demand. Anonymous articles had gone by the board, and it was natural to require names for publication. The only influence that would check advertising was the good spirit of the profession itself. Medical men who wrote much fell in the estimation of their fellows.

Dr. LEONARD WILLIAMS said that the public no less than the profession had got into a state of militant hysteria on this subject. There never had been and never could be any such thing as a rule or law prohibiting medical men as such from writing under their own names in the lay press. The warning notice said that if members of the profession must write for the lay press they should remember that they were gentlemen and members of a gentlemanly profession; that was the gist of the whole matter. No one had ever been reproved or reproached by the General Medical Council for writing for the lay press. He had, however, two objections to the warning notice. One was that it went into the matter of the motives of the people who were supposed to have offended—a very difficult matter. Secondly, it was sent out to anybody who had written an article at the instance of anybody who notified the Registrar. So the machinery of the General Medical Council could be employed for private ends. Writing in the lay press under a name was not calculated to fill a consulting-room, in his experience. The British Medical Association was not the only Association that could act as "common informer" to the G.M.C.—there were the defence associations; but if the medical profession were dissatisfied with any of these bodies the remedy lay in electing to their government persons in whom they had more trust. The press, in many instances, was just as capable of judging when an article was objectionable to the public as was any ethical committee. He held that it was the duty of those of the profession who could write to educate the public. The elementary laws of health and personal hygiene had never been taught to anybody, and the result of "a silent profession" in the past was that the war revealed us as a C 3 nation. By remaining silent the profession laid itself open to the disgusting imputation that it pursued the policy in order that people might remain ill to benefit the pocket of the doctor.

Dr. T. HYSLOP said that this question would find its own level. We had heard much of it, expressed in language both temperate and intemperate. There was not much fear for the profession, as men who advertised would always fall in their fellows' esteem, but there was cause to fear for the sake of the public. If one column in a newspaper gave legitimate information on health matters, others talked the most contemptible nonsense. It was time a truce was called in what was becoming a tedious controversy; enough had been said to make every medical man realise the gravity of the situation.

Lord RIDDELL briefly replied, reiterating the view that the G.M.C. had exceeded its functions in the matter of the first warning notice.

IRELAND.

(FROM OUR OWN CORRESPONDENT.)

Dublin University Biological Association.

ON Nov. 13th, in Trinity College, Mr. R. Atkinson Stoney, President of the Dublin University Biological Association, read an inaugural address on cancer. He covered the entire field of cancer research in a clear way, and discussed the various methods of treatment in vogue, concluding with the opinion that surgery, practised early, still offered the best prospect of cure or alleviation. Mr. Stoney went on to say that at the Royal City of Dublin Hospital they had started a special department for the treatment and investigation of cancer. They had taken over a deep X ray installation from the Coombe Hospital, and were enlarging the hospital and setting aside special wards for cancer patients. It was hoped before long to enlarge the scope of the hospital to embrace investigation of other methods of treatment.

A vote of thanks was moved by Mr. A. Fullerton, President of the Royal College of Surgeons in Ireland, who recounted several cases illustrative of the various problems which arose in regard to cancer. Prof. T. G. Moorhead followed, and made a plea for the education of the public in regard to the early symptoms of malignant disease. This plea was enforced further by Mr. W. Doolin, and Mr. K. L. G. Gunn discussed some broader questions arising out of the consideration of cancer.

A Research Institute for Cancer.

In Mr. Stoney's address to the Dublin University Biological Association he announced the establishment of a Research Institute for Cancer in connexion with the Royal City of Dublin Hospital. It is understood that the directors of the hospital, with the aid of a grant from the British Red Cross Society and of some subscriptions from private sources, have taken a house neighbouring to the hospital, and have fitted it with beds for patients suffering from cancer. Research will be carried on under expert guidance. A scientific committee has been formed, on which the various scientific bodies in Dublin, and the several medical schools will be represented. It is probable that a public announcement of the scope and intentions of the institute will shortly be made.

Physical and Mental Disorder.

In his presidential address to the Ulster Medical Society on Nov. 4th Dr. M. J. Nolan drew attention to the relationship between bodily disease and mental disorder. The normal mind he imagined as a team of physical and psychical factors working in unison, failure in which resulted in dissociation and loss of control. The transmission of the tendency to this failure constituted the so-called insane heredity, which, though not necessarily expressed, rendered the individual liable to breakdown under adverse circumstances. The failure might be of any degree—from idiocy to transient psychical disturbance. Discussing the physiogenic and psychogenic factors called for in official returns, Dr. Nolan suggested that the official factors were too restricted and that to "sexual excess" should be added "sexual deprivation, voluntary and involuntary," and that diseases of the endocrine and lymphatic systems should be included. He laid stress on the evil consequences of contraception as tending to excess. Alluding to the difficulties that faced general practitioners in regard to

certification, Dr. Nolan said that for all practical purposes Mercier's formula, "Insanity is a disorder of the process of adaptation to self," was the safest guide. The same basic instincts and emotions were in operation in all varieties of insanity, but combined in groupings different in kind and degree. The psychological types of character determined the particular form of insanity in each individual, and each individual must be regarded as an entity. In the majority of cases the onset of functional or organic disease could be definitely fixed as the starting-point of the obvious mental disturbance. The symptomatology of insanity, said Dr. Nolan in conclusion, necessitated segregation and treatment by specialists in mental disease, working with a medical staff dealing with general, medical, and surgical work, including pathology and research. The present system could not deal with so-called insanity as efficiently as it might be dealt with, and a more and intimate knowledge of the subject should be gained by students and practitioners.

NOTES FROM INDIA.

(FROM OUR OWN CORRESPONDENTS.)

Tuberculosis in India.

BEFORE leaving for England recently Dr. C. Muthu gave an interesting address on tuberculosis and its treatment in relation to conditions in India. Dr. Muthu has been doing a considerable amount of propaganda work in this country and has helped to create public interest. He has opened a free tuberculosis dispensary in Madras and a home in Pallavaram (Madras Presidency) for the treatment of the disease, and Government has provided land at Thambram for a sanatorium and garden colony which Dr. Muthu hopes to develop soon after his return from England. During his 27 years' campaign against tuberculosis, he said, he had found no specific remedy to cure the disease. All serums and vaccines for tuberculosis had been more or less failures in the long run, and the indiscriminate injection of tuberculin by qualified and unqualified men in India had done immense harm by rousing latent disease, thus killing more people than it had cured. Tuberculosis, he pointed out, was a constitutional disease, taking many years to develop, and there was no royal road to its arrest. The only cure was Nature's cure—the only treatment was to raise the patient's powers of resistance by fresh air, good food, better housing, and more healthy environment. Food, in Dr. Muthu's opinion, was more important than freedom. Tuberculosis was a poverty and filth disease, and it was the duty of Indian reformers and leaders to give attention to improving the health and efficiency of the people. Then, and then only, would a disease like tuberculosis gradually die out as it had done in other countries. Next to food in raising the vitality of the people was the care of women and children. In this connexion he strongly recommended that school hours for boys and girls should be changed to 7 A.M. to noon or 8 A.M. to 1 P.M., including a short interval; children could not take in any knowledge in the hot hours of the day, and the heat imposed a great strain on their growing brains. There was a demand now for tuberculosis sanatoriums all over the country, and this demand would become more insistent as time went on. Sanatoriums alone, however, would not get rid of tuberculosis, though their establishment was undoubtedly the first step, and a very important one. Its good effects would be seen in a few years in the education of the public in all matters of hygiene, sanitation, and right living, the after-care of patients being, of course, as important as sanatorium treatment. In combating tuberculosis, said Dr. Muthu in conclusion, there must be a combined and well-organised scheme to deal with all phases of treatment. This was the reason why a sanatorium and a garden colony met the needs better than a sanatorium alone.

Epidemic Diseases in Madras Presidency.

The annual report of the administration states that cholera was very severe during the year 1924-25 compared with the two previous years. In Trichinopoly, where 1511 deaths from this disease were reported, the outbreak is said to have been due to the failure of the protected water-supply owing to the bursting of the main at the time of the Cauvery floods. Mortality from small-pox fell from 2353 to 1623, and of this total Rajahmundry alone was responsible for 579, or more than a third of the total deaths. There was considerable improvement in the vaccination work, the number of successful cases rising from 92,880 to 133,491—i.e., from 37·1 to 53·3 per 1000 of the population. In addition, 35,352 cases were successfully revaccinated. Plague was responsible for 1955 deaths, as compared with 1331 in the previous year. Of this total 1165 deaths occurred in Salem alone, while Periykulam reported 256, Dharapuram 205, and Pollachi 204. Influenza was practically absent throughout the year.

Indigenous Medical Systems.

A month or two ago the Government of the United Provinces established a Board of Indian Medicine to advise the Government on all questions connected with the ancient systems of medicine. This Board, over which a layman presides, will prescribe courses of study, appoint examiners, confer diplomas and degrees, register practitioners, and distribute Government grants. The Government has also accepted a recommendation that the Ayurvedic College of Benares and the King's (Unani) Hospital at Lucknow be raised to the status of State-aided colleges. Discussing the work of the new Board, the *Pioneer* points out that although before the reforms the encouragement of indigenous medical systems was frequently discussed, it never got anything more than sympathy from the Government, and certainly such systems would never have been officially recognised. Yet, says the writer, whatever their abstract merits, the Ayurvedic and Unani systems inspire a certain amount of confidence in the people at large and it would be foolish to disregard the knowledge acquired and handed down through many generations. A more convincing argument, perhaps, is that the facilities for European medical treatment in rural districts are still meagre, and there is scope for Indian practitioners to do what they can in providing relief in these areas. Wherever the various systems are in competition they may safely be relied on to show their respective merits as time elapses. In Madras Presidency there are 13 Ayurvedic dispensaries and one Unani dispensary maintained by municipalities, and an application recently came before the Bombay Corporation for funds to maintain a local dispensary at which, it is stated, there is a large and increasing attendance.

Elimination of Malaria.

Some time ago Major H. W. Acton, director of the Calcutta School of Tropical Medicine, issued an appeal for funds to establish a chair of malarial research. His appeal is associated with the name of Sir Ronald Ross, who is shortly to pay a visit to India, and the chair would be set up in the hope that methods could be devised for eradicating the disease in the various districts of India, each of which presents its own problems. Commenting on the proposal, the *Times of India* says that "a memorial scholarship named after Sir Ronald Ross would be an excellent thing; but so long as what we are pleased to call the First City in India is 'reeking with malaria' such a memorial would be a gibe instead of a grateful tribute." A clean and healthy Bombay would be a more proper monument. For practical purposes, it is suggested, enough is already known of the habits of the mosquito, and what is wanted is an army of inspectors trained to deal with the breeding-places of anopheles. Such work should be undertaken and financed by the municipality, but owners of property where mosquitoes breed should be made to feel their responsibility, as in other parts of the world. A permanent advisory

committee will probably be set up to coördinate measures against malaria in Bombay, but will not be given executive power as the military, the G.I.P. railway, and the Port Trust authorities have their own staffs engaged in this work. The Corporation, it is stated, has ample powers for the reclamation of low-lying land.

Flannel Shirts.

The shirts of the army in India have hitherto been made exclusively of flannel, and no other material has been recognised by the Regulations; they have been issued impartially to all troops, whether suffering from heat or from cold. A new Army Order permits both British and Indian troops to maintain a couple of cotton shirts in place of the flannel. Too sudden and violent a reform, however, is guarded against by the provision that the Ordnance shall not issue cotton shirts and that their use cannot be allowed on service. The official reluctance to dispense with universal flannel is, of course, an expression of belief in woollen garments as a protection against chill, and is consistent with the use of body-belts in the tropics. A young soldier, free to wear cotton clothes, may be less careful to keep warm at sundown than the more experienced resident.

An Antirabic Centre.

During the year ending Feb. 28th, 1926, 572 patients were treated at the Pasteur Institute of Southern India, Coonoor. In addition 4644 patients received antirabic treatment at local centres. The report of the director, Lieut.-Colonel J. W. Cornwall, states that statistics collected over a number of years show that on the average 1 out of every 36 persons bitten by rabid animals dies of rabies after treatment with serum, whereas the death-rate amongst those untreated is 1 in 16. It is calculated that during the 12 years 1913–24 at least 60,000 people in the Madras Presidency were bitten by rabid animals, and that about one-sixth of them received treatment. At the end of February last the virus at the Institute was in its 973rd passage.

Medical Relief in the Punjab.

A scheme of medical relief formulated by the Punjab Government last year arranges for the opening of 375 dispensaries as soon as possible. One dispensary is to be furnished either for each 30,000 of population or for each 100 square miles of territory, as may be best adapted to local conditions. Besides rural dispensaries it is intended to have a hospital of 12 beds for each tahsil (corresponding roughly to a rural area) and a first-class hospital at the headquarters of each district (county). These hospitals will be centres to which the more serious medical and surgical cases can be sent from village dispensaries of the surrounding area.

An Indian Nursing Service.

A Nursing Service for Indian Troops' Hospital has been constituted as from Oct. 1st. This service will be formed of lady nurses recruited within Indian limits for employment in hospitals for Indian troops. The nurses will supervise, train, and instruct the nursing section of the Indian Hospital Corps.

A Bill for the registration of medical men in Delhi and the Frontier Provinces has been published. The Punjab Medical Council will control registration in these two areas, which will be represented on the Council by three members.

In accordance with the recommendations of the Cattle Committee appointed last year it has been decided to establish breeding herds at Patna and Cuttack, where there is a large demand for milk. At the Patna farm plant for pasteurisation will be provided.

Army contractors have submitted a petition against the proposed creation of a branch of the Navy, Army, and Air Force Institute in India to replace the Army Canteen Board which is being abolished.

Two prominent Parsis have made an offer of 32 lakhs of rupees (nearly £250,000) to build a medical hospital adjoining the King Edward Memorial Hospital so that this institution may be reserved entirely for surgical cases.

During 1925 over 642,000 rats, alive or dead, were sent by the Bombay municipality to the Haffkine Institute to be examined for plague. Up to the end of the year the Institute had supplied nearly 26,000,000 doses of plague vaccine, for which, it is stated, there is an increasing demand.

It is reported that about 500 prisoners in the Hyderabad (Sind) central jail have contracted scurvy.

The Lady Chelmsford All-India League for Maternity and Child Welfare is arranging a conference to be held at Delhi in February.

The annual report of the Madras Medical College notes an increased percentage of failures in medicine, surgery, and midwifery which is partly attributed by the principal to the change in character of the examination, greater importance now being attached by examiners to the clinical and practical sides of each subject.

BUCHAREST.

(FROM OUR OWN CORRESPONDENT.)

Competition against Doctors.

THE majority of Rumanian practitioners are having a hard struggle for existence. Some superficial observers believe that the cause of this is an undue increase of the number of physicians, and that we are approaching the so-called mental proletariat. Certainly this has something to do with it, but it is not the origin of the trouble. According to Dr. E. Spirt, who gave a lecture on this subject at a recent meeting of the Rumanian Medical Association, the real cause is the all-round illegal competition which the profession has to put up with. First of all there is the competition of medical students; some 80 per cent. of the students who have attended two sessions and learnt to give an injection and to use surgical dressings begin to practise at once, instead of attending the university lectures, and they freely advertise themselves in the papers. There is hardly a single family in Bucharest which has not a relative who is a medical student and whom they recommend to their friends, thus distracting a great number of patients from the qualified doctor. Dr. Spirt mentioned, for instance, the case of a fourth-year student who has at his home a gynæcological table and a regularly equipped consulting-room, and, of course, as such students do not pay taxes and have no family, they are able to treat patients at greatly reduced fees. Another anomaly is the attitude of midwives, who openly advertise that they receive and board female patients and obstetric cases. It would be difficult to find any midwife who does not practise not only gynæcology, but also general medicine—let alone the procuring of abortions, which is a side industry. It is strange that even the chemists, whose interests are allied to those of the medical profession—since doctors do not dispense their own medicines—do great harm as competitors. Most dangerous amongst them are those who have the degree of "doctor." Seeing this word on their boards, the public think that they are medical doctors, and this source of error is often exploited. Lately a case came before the County Court, where a pharmacist who kept a profitable consulting room in the outlying part of the city was sued for unskilful treatment, and fined by the Court. There is also a class of patients who never consult a medical man, but go straight to the chemist's shop, where, perhaps, they get medical advice from some junior apprentice and buy from him the most expensive medicines. Druggists, who are forbidden to sell compound medicines, do great harm to the doctors by selling specialties to patients without medical prescription, and by supplying them even with

opiates, morphine, cocaine, and ether, not to speak of corrosive sublimate, aspirin and pyramidon, which are sold wholesale as regular household remedies. Not less harmful is the competition of barbers and other quacks. Some of them affix the title of "Chirurg" (surgeon) to their name-plate, and perform minor operations, extract teeth, give injections, and apply surgical dressings. Recently a barber sued a "patient" for unpaid fees, and proudly alluded to a whole series of persons whose gonorrhœa, gonorrhœal rheumatism, and ulcers he had cured. The difficulties of the doctors are also greatly increased by the innumerable so-called Mutual Aid Societies against Death and Sickness; it is no exaggeration to state that in Bucharest alone there are 80 of these societies. Every one of them registers at least three or four thousand members, mostly families, and each employs two or three physicians, generally paying them 3,000 to 5,000 lei (£3 to £5) a year—less than the wages of a butler. By exploiting medical work at salaries which should rather be called tips, the societies manage to accumulate large fortunes. The Medical Association appreciates the importance of speedy action, and has appointed a commission to devise legislation for the remedy of this deplorable state of affairs.

Campaign against Venereal Disease.

In the post-war years the amount of venereal disease increased very considerably in Rumania. The increase is most noticeable in the small towns and villages, where the population—the clean, rustic folk—was more or less exempt from venereal disease before the war. The Rumanian Government realised at once that the best weapon against this evil is the enlightenment of the public, and accordingly organised several expeditions, in which skilled medical staff travel on caravan motor-cars from village to village, giving explanatory lectures on the importance of early medical treatment and on the prevention of these diseases. The motor-car is equipped with a small laboratory for treatment, and for taking specimens of blood. Explanatory leaflets are distributed among teachers, priests, and other intelligent men, instructing them how to carry on and continue the work thus begun. In large towns free dispensaries have been set up, where venereal cases get free treatment. The Chamber of Deputies passed a law obliging doctors to notify all fresh cases of venereal infection—omitting the names of the patients—and the data thus collected have shown a decided diminution in the number of fresh infections in recent years as compared with those just after the war. Notification has also revealed the fact that the institution of licensed houses does not in any way contribute to the decrease of venereal infection; it even shows that venereal disease is chiefly distributed by the brothels, where the resistance of men is considerably influenced by the action of alcohol. This has induced the Government to consider the abolition of licensed houses; from the end of this year the system will be discontinued in certain cities, and if the results are satisfactory the change will be made universal throughout the country.

VIENNA.

(FROM OUR OWN CORRESPONDENT.)

A Congress of Urology.

THE Seventh Congress of the German Society for Urology was held in Vienna during the first week of October under the presidency of Prof. Viktor Blum (Vienna). The attendance was large, and besides representatives from the German-speaking countries, a number of surgeons came from France, the United States, Italy, Switzerland, Russia, Turkey, and Czecho-Slovakia. More than 150 papers were read dealing with three main subjects—the pathology and treatment of anuria, the pathology and treatment of malignant growths of the bladder, and the significance and treatment of pain in urological practice. The last of these was discussed on the first day. Prof. P. Albrecht (Vienna) reporting on his experiments with general anæsthetics in urology, stated he had come to the conclusion that chloroform should not be employed in this work and advocated the use of dichloren, a comparatively new but useful and harmless anæsthetic.[1] Dr. O. S. Lowsley (New York) expressed himself as strongly in favour of local anæsthesia, and showed excellent photographs and films to illustrate his method of regional infiltration in urological operations. Dr. G. Illyés (Budapest) also recommended purely local anæsthesia, on the strength of experience in 700 operations on the kidney, besides work on the ureter and bladder. In the discussion the majority of the surgeons were in favour of the local method, and, in summing up, the president pointed out that the large majority of urological operations can now be done under local anæsthesia, which is, of course, especially useful where the condition of the patient makes general anæsthesia risky. Each case must necessarily be judged on its merits, for both methods have their advantages and disadvantages.

The opening paper on anuria was read by Prof. Theodor Fahr (Hamburg), who discussed the morbid anatomy of the condition, showed the atrophic state of the kidney-tissue, and the microscopical features of acute anuria, and emphasised the need for clinical observer and morbid anatomist to join forces so as to clear up the many problems which the condition still presents. Dr. Paul Jungmann (Berlin) pointed out that anuria can be produced by factors in the kidney itself (inflammation destruction of tissue) or by external factors such as a fall of blood pressure, or a loss of body fluids, or the action of toxins. The treatment of anuria—especially of the so-called reflex anuria—was discussed by Dr. Hans Rubritius (Vienna), who said that when there was no mechanical obstruction, decapsulation might be useful. On the whole, it must be admitted, the discussion did not bring out any very novel views of the development or treatment of the condition—except, possibly, a contribution by Dr. Lichtenstern (Vienna), stating that reflex anuria can only occur in the presence of an already damaged kidney.

Dr. L. Casper (Berlin) reviewed the methods of making the upper urinary tract visible by the use of liquids relatively impermeable to X rays. The problems of the physiology of the ureter and its occlusion were freely discussed and experiments were reported on production of cystic dilatation in the lowest part of the ureter and on denervation of the ureter, which causes, it is asserted, a dilatation of the renal pelvis.

The last day was devoted to considering malignant disease of the bladder. In spite of decided progress, the pathology and treatment of vesical tumours is still somewhat obscure. In the present state of knowledge the treatment should be radically surgical, but often it is ineffective, particularly as neither patient nor surgeon is willing to sacrifice the whole bladder where only a small carcinoma is present. No operation other than total extirpation of the bladder can, however, be expected to give satisfactory results in malignant disease, even where the lesion is of slight extent. In the discussion it was pointed out repeatedly that it is better not to remove a cancer of the bladder at all than to perform non-radical operation, for insufficient removal of the tumour is likely to cause rapid propagation of the disease. Ulceration and hæmorrhage can be controlled by intravesical methods such as fulguration or thermo- and chemo-coagulation, and the chief complaints can be soothed in this way. An interesting paper was contributed by Dr. Karl Scheele and Dr. Oppenheimer (Frankfort) on the Appearance of Vesical Tumours in Labourers Handling Aniline. They consider the formation of tumours in these workers to be due to chemical irritation by aniline and to its disintegration or splitting; the handling of end-products does not cause the lesions. Dr. Bauer (Vienna) has produced

[1] THE LANCET, 1926, i., 154.

vesical tumours by repeated painting with tar; these new growths, however, differ in their histology from all other known vesical tumours. Dr. F. Oehlecker (Hamburg) described the advantages of blood transfusion both before and after operation, and Dr. Salib (Constantinople) showed an interesting case in which there was a double penis and other malformations of the urogenital system.

Death of Prof. Ehrmann.

The name of Prof. S. Ehrmann, who died unexpectedly a few days ago, was well known beyond the narrow frontiers of our small Republic. Born in a Bohemian village in 1854, he took up medicine in Vienna and soon became celebrated amongst the students and professors for his gift for drawing. Prof. Brücke made him assistant in the Physiologic Institute, and there Ehrmann undertook his first important contribution to science—an investigation of the formation of pigments in the skin and the cause of the different colours of the various human races. Definitely turning to dermatology, he studied under Kaposi and Neumann. As long ago as 1887 he was investigating the course of syphilitic infection in the human body, and was working at the histology and physiology of the skin, thus laying foundations of our knowledge of the relations between skin diseases and metabolic changes. He was the first to show the presence of spirochætes in the nervous substance in tabes and general paralysis of the insane, and his excellent illustrations—all painted by himself—of skin conditions in health and disease, as published in his "Diagnostic Atlas of Dermatology," are remarkable in their technique. The fight against venereal diseases was part of his life work and he stood foremost in this campaign. He also attained an enormous private practice, owing to the knowledge and skill that he possessed. A very short, disproportionately built person, he had wonderful artistic feeling and knowledge, and got together a fine collection of treasures, besides assisting many artists and painters. In spite of severe handicaps through his religion—he was a Jew—he managed to attract a large number of students to his private laboratory and hospital wards, and his pupils have attained high standing all over the world.

SOUTH AFRICA.

(FROM OUR OWN CORRESPONDENT.)

Medical Congresses at Pretoria.

A SERIES of medical congresses were held at Pretoria in October—the most important being the South African Medical Congress. The decision to form a Federation of the British Medical Association in South Africa and the South African Medical Association was the subject of congratulation by Lord Athlone, who addressed the delegates at a banquet held in their honour. He added that the Great War had opened our eyes to the number of persons who were unfit from preventable causes, and that there was now a widespread belief that the human wastage caused from ill-health could be very much reduced. It was to the medical profession that they looked for the guidance of the nation's aspirations towards better health, which were often confused and ill-directed, into proper channels. The child welfare conference was held on Oct. 12th. One of the most interesting papers contributed was read by Dr. J. J. Boyd, medical officer of health, Pretoria, on "Maternal Mortality and Morbidity." Dr. Boyd recommended that a post-graduate course for medical practitioners, trained nurses and midwives should be provided at several of the larger towns of the Union; also the establishment of antenatal clinics in larger towns. He advocated the control of midwives by the local health authorities, and a Government subsidy for qualified midwives in rural districts.

Dr. J. A. Mitchell, Secretary for Public Health, congratulated Dr. Boyd on his paper, and said that the Government Health Department felt the need for more statistical data. More and better trained midwives were wanted in South Africa, for unqualified, ignorant, and dirty midwives were taking a heavy toll of both mother and infant. Dr. Mitchell advocated a state-subsidised medical service for the rural areas. A paper on Birth Control, read by the Rev. J. B. Watson, was followed by a lively discussion. Mr. Watson, dealing with the need of a better race and with the tendency to over-population, considered that it would not be unreasonable to ask that the mating of the diseased, unfit, defective and degenerate should be prevented. There should be prohibition, he submitted, of early marriages. In one year in the Transvaal 700 girls under 17 contracted marriage. Dr. Jane Ruthven held, on the other hand, that the hindrances to marriage should be curtailed. and Mrs. Miriam Walsh (Capetown) and others pointed out the paramount value of white children to South Africa.

On Oct. 14th Dr. George Campbell, the new President of the Child Welfare Congress, proposed:

"That the necessity be urged for sterilisation of the mentally deficient, both white and coloured, where such incurability is an active menace to the patients themselves or to the welfare of future generations, or, alternatively, segregation in colonies, preferably farm colonies."

Sterilisation, he said, was an extremely simple operation which did not interfere with the life of those operated upon, and it was the duty of those who were fit to prevent the bearing of children who would be incapable of facing the world. It was often said that it was cruel to interfere with Nature, but in his opinion the unrestricted effects of Nature were more cruel still. The resolution was seconded by Dr. Shadick Higgins, who favoured segregation of the mentally deficient. Mr. A. A. Stanford, the Johannesburg children's magistrate, speaking of propagation by people of low mentality, said that one Johannesburg family had directly cost the State £2000. Dr. Campbell's resolution was passed with only six dissentient votes. After long discussion of a resolution favouring the teaching of contraceptive methods no decision was reached and the whole question of birth control was referred to the National Council of Child Welfare for investigation.

Massage and Medical Gymnastics.

The second annual meeting of the Central Governing Board of the South African Society of Massage and Medical Gymnastics was held at Johannesburg from Sept. 27th to 30th last. Delegates from the Cape Province, Natal and the Transvaal were present. The agenda included: (1) certificates to be recognised by the Society; (2) the proposal to establish a training school for physiotherapy at the University of the Witwatersrand; (3) action to be taken by the Society in regard to the position of members under the Medical, Dental and Pharmacy Bill; (4) a register of masseuses seeking employment to be kept at the Head Office, and by branch secretaries; (5) appointment of a Headquarters Committee in Capetown. Mrs. Dircks, the president, in the opening address, referred to the growth and wider recognition of the Society since its formal inauguration in December, 1924, and outlined the work that had been accomplished during the past year.

Plague Menace.

The grave warning issued by the Union Government Public Health Department to local authorities in regard to the menace of plague in connexion with seasonal increase of rodents has been followed by a big campaign against rats throughout the Union. In the plague outbreak of 1925-26 no less than 50 lives were lost before the danger was suppressed. It is again pointed out by the Public Health Department that the seasonal increase in the activity of rodents and fleas may be expected to occur within the next few weeks.

The Late Dr. Howell Davies.

Dr. Howell Davies, who has died at Pretoria, Transvaal, was born at Carmarthen in 1871, and received his medical education at St. Bartholomew's Hospital. At the outbreak of the Boer War Dr.

Davies went out to South Africa as a civil surgeon, and gained special recognition for services in connexion with the reorganisation of the large camp at Irene. After the close of hostilities Dr. Davies settled in practice at Pretoria. He was at various times president of the Pretoria Branch of the British Medical Association, and at the recent amalgamation of the B.M.A. with the South African Medical Association was elected Chairman of the Pretoria branch of the dual association. He acted as Government district surgeon for Pretoria, and for 15 years was honorary surgeon of the Pretoria General Hospital. Just before his death he was elected President of the 21st annual South African Medical Congress, held at Pretoria recently.

MEDICINE AND THE LAW.

Dangerous Drugs: "Direct Personal Supervision."

A MOST important decision of the High Court, given on Nov. 11th, explains the liability of a medical practitioner in the matter of keeping a register or day-book under the Dangerous Drugs Act Regulations of 1921, and places a common-sense interpretation upon the words "administration of the drugs by or under the direct personal supervision of a duly qualified medical practitioner" in the proviso to Regulation 4. It will be remembered that Dr. G. C. Kingsbury was fined £25 by the Lord Mayor a little while ago for having supplied morphine to a patient without entering in a register the particulars required by Schedule 1 of the Regulations, including the name and address of the person supplied. No suggestion was made which reflected on Dr. Kingsbury's character; the offence was regarded as entirely technical. The proved or admitted facts were that Dr. Kingsbury became a barrister in 1902 and practised law from that date, but occasionally gave medical treatment to old friends and patients without fee. Two of the latter sought his help to cure them of morphine addiction. The first of these was cured before the end of 1924; the other was treated by the method of gradual reduction, the daily dose being brought down to one-fiftieth of that taken by the patient originally. Dr. Kingsbury saw this patient every other day, even during his own holidays; at each visit he left the dose for the day and the succeeding day with instructions as to the time and method of taking it. He did not actually see the patient take the dose, but he was satisfied that he would have known if the patient was getting morphine from other doctors. Was this an "administration of drugs by or under the direct personal supervision" of a qualified practitioner? If so, Dr. Kingsbury was protected by the proviso to Regulation 4, which states that such administration is not to be deemed a supplying of the drug for the purpose of the Regulation which requires the keeping of a register or day-book. During the argument on appeal, the prosecution said that the words "direct personal supervision" were the strongest possible; it was emphasised that the patient might have taken his two days' supply in a few hours. Lord Hewart asked a pertinent question: "Suppose a doctor personally administers a dose of medicine to a patient at 11 A.M. and says, 'If his temperature rises a degree, give another dose to-night; otherwise wait till I see him again at 11 A.M. to-morrow'—would that be 'direct personal supervision'?" Mr. H. D. Roome, for the Director of Public Prosecutions, answered frankly in the affirmative, saying it would be oppressive to hold otherwise. This was really the crux of the case. It was true that another Regulation provided for cases of emergency, and counsel suggested that the idea might be imported into the proviso to Regulation 4 so that the doctor should only be protected under the proviso if the drug was taken in his actual presence or if it was a case of emergency. As the Lord Chief Justice observed, this was not what Regulation 4 said. He considered there had been direct personal supervision and, without discussing the amendment of the Regulations, he announced that the appeal must succeed and the decision of the Lord Mayor must be upset. The appellant had also argued that the Regulation was ultra vires, because the general words of the Act related to the manufacture, sale, distribution, and possession of drugs and not to the prescribing and dispensing of drugs by medical practitioners. The object of the Act was to stop improper drug traffic, not to interfere with the confidential relations between doctor and patient; the power in Section 10 of the Act, for instance, enabling constables to enter and inspect books, could hardly be taken to justify a policeman in entering a doctor's surgery and demanding to see the names and addresses of patients. The Court, having given its decision on another ground, did not require to deal with the ultra vires point, which may, however, be put forward again shortly in another appeal.

Milk Deficient in Fat: Unsuccessful Prosecution.

Once again the prosecution of a farmer for selling milk deficient in fat has failed. A charge at Walsingham Petty Sessions on Nov. 1st alleged that the sample contained only 2·61 per cent. of fat instead of the 3 per cent. which is the prima facie minimum prescribed by the Sale of Milk Regulations of 1901. Once again the defence seems to have been unable to rebut the analysis put forward by the prosecution, but once again the defendant escaped by calling evidence that the milk had not been tampered with. The farmer, who had otherwise an unblemished record in the matter of milk purity, explained that the milk roundsman had run short of milk and had come back for another two gallons. These were obtained from the milk of two cows which had recently calved. As is clear from the evidence at previous prosecutions the forepart of the milk drawn from a cow which has recently calved is deficient in milk-fat—a fact of which farmers are presumably aware. Thus it happens that, while the milk they sell is genuine and undiluted milk, the purchaser gets something below the prescribed standard and has no warning of the fact. The purchaser is safeguarded in the selling of certain other kinds of milk; the Condensed Milk Regulations, for instance, insist that condensed machine-skimmed or condensed skimmed milk (sweetened or unsweetened) is to be labelled "Unfit for babies." The same warning must be given on the sale of dried machine-skimmed or dried skimmed milk under the Dried Milk Regulations, which also provide that dried partly-skimmed milk (containing not less than 8 per cent. but less than 26 per cent. of milk-fat) shall bear the words, "should not be used for babies except under medical advice." The whole trend and purpose of the Sale of Food and Drugs Acts is to ensure that the purchaser gets an article of standard quality. Farmers will have only themselves to thank if public opinion demands legislation compelling them to declare by some means to the purchaser the fact that the milk sold is, or from the circumstances of the milking may be, below the standard of 3 per cent. of milk-fat. It is a matter in which the National Milk Conference may well give a lead.

The Kynaston Case.

Lieut.-Colonel John Kynaston, R.A.M.C. (retired), was fined £10 at the Central Criminal Court on Nov. 15th for aiding and abetting the obtaining of a dangerous drug (medicinal opium) contrary to a regulation made under the Dangerous Drugs Act of 1920. His name had been removed from the medical register in 1922, but he had continued to practise as a doctor, and on Aug. 25th he gave a prescription containing powdered opium to a patient suffering from nasal catarrh. The prescription was signed "Lieut.-Colonel John Kynaston, R.A.M.C. (retired), M.R.C.S., and L.R.C.P. (London)." The Dangerous Drugs Act and Regulations prohibit the possession of forbidden drugs except under licence or on the prescription of a "duly qualified medical practitioner." The prosecution said these latter words had only one meaning—namely, a practitioner whose name is on the medical register. The defendant said

"duly qualified" did not necessarily mean "registered." The jury's verdict was "guilty," and the Common Serjeant inflicted a nominal fine, taking into account the defendant's bona fides. Lieut.-Colonel Kynaston intimated that he would probably appeal, and, indeed, if there is any doubt as to the law, that doubt had better be promptly removed. It is, perhaps, remarkable that the various Dangerous Drugs enactments use so many different expressions to describe the doctor. The Act of 1920 talks merely of "medical practitioners" (in Section 7); the Act of 1923, in a passage dealing with poisons rather than dangerous drugs, speaks of the "registered medical practitioner"; and the Regulations of 1920 use the expression "duly qualified medical practitioner," coupling it with "registered dentist" and "registered veterinary surgeon."

The actual legal point before the Central Criminal Court was a narrow one. The defendant, as appears from his evidence, sought to enlarge the case by bringing in questions of the justice or injustice of the removal of his name from the register in 1922 for advertisement. These questions were irrelevant. If he claims that he did not advertise or that his advertisement was not improper, the Central Criminal Court is not a tribunal of appeal from the Medical Council. If he contends that the Medical Council acted with bias or that the Colleges had no legal right to deprive him of his diplomas, then his legal remedy lies elsewhere. As an offence against the Dangerous Drugs Act his offence was trivial, but the wider issues he raises are serious. What would be thought of a solicitor who, having been struck off the rolls, continued to call himself an admitted solicitor? Or of a barrister who, having been disbarred, claimed still to describe himself as a barrister-at-law? The more publicity Lieut.-Colonel Kynaston's case receives the more clearly appears the following truth, which the public has not always fully appreciated. Neither the absence of medical diplomas nor the absence of his name from the pages of the medical register prevents a man from practising as a doctor.

POLIOMYELITIS AT BROADSTAIRS.

THE following letters, referred to in our editorial columns, were issued to the parents of each child in a group of schools in the Isle of Thanet in connexion with the recent outbreak of poliomyelitis.

(I.) Oct. 20th, 1926.

Epidemic poliomyelitis (infantile paralysis) is unfortunately prevalent in certain districts in England.

The majority of the cases are mild and leave no permanent disability. On the other hand, a few of the cases are serious either on account of their severity or because some vital part of the nervous system happens to be attacked.

The disease is somewhat prevalent in the Isle of Thanet, and with a view to its prevention we are giving the following responsible opinions and advice in the interests of certain schools at Broadstairs.

The disease has an incubation period of not exceeding seven days, and is conveyed from person to person.

Its infectivity is greatest at the onset and often before the patient has shown any symptoms, but the infectivity declines rapidly when the disease is established.

A number of cases are so mild as to produce no appreciable feeling of illness and the individuals thus lightly attacked, though themselves escaping, are liable to infect their comrades.

Our advice is that all boarding schools in the district, whether they have cases or no, should isolate themselves from outside human contact, and for the time being become self-contained communities. If there are day scholars at any school they should for the time being cease their attendance.

We advise that each school as a self-contained community should continue its work and its play subject to certain modifications. Close assemblages should, as far as possible, be avoided or shortened, for instance, chapel services should be curtailed. Ventilation and open air which are prevalent customs in all schools should be given additional prominence.

The pupils of each school should wash the mouth and throat three times in the 24 hours under medical direction, together with other measures advised.

If these means are pursued parents may be assured that their children will be better protected than if the schools are broken up and for these reasons:—(1) A self-contained community like a school can be independent of the outside world, and, therefore, protected from infection; (2) the ordered life of work and play enhances resisting power.

In addition to the ordinary care of health pupils can be kept under skilled observation, and, therefore, the disease would be detected in its earliest stages, for it must be remembered that the symptoms may be so slight as to easily pass unnoticed not only by relatives, but even by a doctor, unless his knowledge of the prevalence of the disease would prompt him as a matter of routine to apply the special tests in investigating the case. Further, no instance has been recorded of a patient spreading this disease while under treatment in hospital.

During the period of quarantine, during which no boy or girl should leave the ground of his or her school, it is important that circumspection should be practised with regard to the visits of parents to the schools.

It may be added that Sir George Newman, the Chief Medical Officer, Ministry of Health, is taking such action in the general community in the Isle of Thanet as is practicable.

(II.) Nov. 5th, 1926.

We think it might be of assistance to parents if we were to issue a further statement concerning the epidemic of poliomyelitis at Broadstairs.

1. The measures taken have been successful. No fresh cases of the illness have occurred in the whole district since Friday, Oct. 29th.

Since the incubation of the disease is usually not more than three days, and never more than seven, it will be seen that the position is satisfactory.

To make the position, however, still more secure it has been decided to continue the quarantine in the schools for a period of three weeks from the last cases; thus, if the present favourable position continues, the quarantine of the schools will end on Friday, Nov. 19th.

2. In our opinion it will be quite safe for parents to pay their "half term" visits to their children on or after Nov. 12th. To ensure absolute security we advise on such "half term" visits parents should either stay in the schools or should take their sons or daughters by car to some place like Sandwich Bay where it is known no case of the disease has occurred.

3. As regards the return to school for scholars who have been removed by their parents on account of the epidemic, such scholars may be sent back to school 14 days after the occurrence of the last case in Broadstairs, that is, as at present advised, on or after Nov. 12th.

It will be necessary that such scholars should be isolated in or about their homes (that is avoiding all visits outside) for four clear days before their return to school.

The last part of their journey should be by car from Margate direct to the school. On their return they will be isolated at school for a further period of three days.

4. Anxieties have been expressed by some parents as to whether Broadstairs will in future be an infected area.

Such an idea is in exact opposition to the facts. The infection does not exist in *places*. Broadstairs, as a place, has never been infected.

The infection resides in certain people, and is conveyed from one person to another.

When this epidemic is over, as it promises very soon to be, Broadstairs will be *more* secure from this disease than the rest of the country, because those susceptible will have had it and immunity will have been established.

The letters were signed by Lord Dawson, Dr. James Collier, and Dr. E. G. Moon.

A CORRECTION.—We regret that the word "tabloids" was twice employed in our last issue (THE LANCET, Nov. 13th, p. 1027), instead of the word "tablets." "Tabloid" and "tabloids" are, of course, registered trade marks and can only be used to describe the special products of Messrs. Burroughs Wellcome. The error occurred in a communication from our Berlin correspondent.

LONDON STREET ACCIDENTS.—In the Metropolitan police district in the three months ending on Sept. 30th, there were 269 fatal and 26,727 non-fatal accidents, which is at the rate of more than 1000 fatal accidents and 107,000 non-fatal ones per annum. The largest number of misadventures was caused by private motor-cars, followed at a long distance, by commercial motors. Pedal cycles, which come next, were slightly more dangerous than motor cycles.

Public Health Services.

SCHOOL MEDICAL SERVICE.

THE following are statistics taken from the reports for 1925 of school medical officers in two districts.

Name of district.	No. on roll.	Av. elem. school attendance.	No. of routine children examined.	No. of special examinations and re-inspections.	Percentage of children found on routine examination requiring treatment.*
Warrington C.B. ..	13,180	—†	4,013	4,491	17·16
Nuneaton ..	7,789	6,667	1,133	8,308	13·3

* Excluding uncleanliness and dental defects. † Not given.

Warrington.

Dr. G. W. N. Joseph, in his thirteenth report on school hygiene, makes some interesting observations on the planning of new schools, and refers to the use of special glass which allows the passage of ultra-violet rays through the classroom windows. It is noted that, although verminous heads and impetigo have become much less common during the past six years, there has not been the corresponding decrease of enlarged cervical glands that might have been expected. The percentage of children showing very defective nutrition has grown from 0·9 in 1924 to 1·3 in 1925. An epidemic of measles started about the middle of June and went on till the end of the year. The number of cases was greater than in any other year of the Warrington records. In May, 1921, arrangements were made for treatment to be given twice weekly in every school in the borough, and results have been very gratifying. The nurses are said to be unanimous that this work at the schools is doing more good than the work previously done at the clinics. It will be seen that in 1925 only 18,553 school attendances were lost in consequence of minor ailments, compared with 104,453 in 1918—a saving of 85,900 attendances. Any extra cost involved by the larger staff of nurses can thus be practically defrayed by the large saving of grant. Children with enlarged tonsils and adenoids are operated on at the infirmary at or about 11 A.M. on Friday mornings, and remain there until 4.30 P.M. At this time the Health Department Ambulance removes them to their own homes. After the operation the child attends from time to time at the school clinic, where nasal douching, etc., is done if necessary. A leaflet on breathing exercises for the child is given to the mother, and a notice is sent to the head teacher of the school stating that the operation has been done, and asking that the child shall be corrected for mouth-breathing.

There are no open-air schools (day or residential) in Warrington. The account given of the Warrington occupation centre is interesting and valuable. An inquiry was made at the end of 1925 to see to what extent children needing spectacles continued to wear them after leaving school. A questionnaire was prepared, and the nurses filled in certain particulars in the course of their usual visits to the home. Altogether 163 children (83 boys and 80 girls) had left school during that time wearing glasses for the correction of defects that rendered the vision worse than 6/12 in at least one eye. Of these 163 children, 106 (56 boys and 50 girls), or 65 per cent., had discontinued wearing glasses after leaving school. This discontinuance appeared to be quite irrespective of the amount of visual defect present at the last examination. The report of the inquiry gives in detail the various reasons for which the children ceased to wear their glasses, and it offers so much food for thought as to be well worth reading in full.

Nuneaton.

Dr. P. G. Horsburgh points out that the number of routine inspections during the year was very low. This was due to epidemic of small-pox and to the change of school medical officers in July of the year. Small-pox, he remarks, is a disease of choice, but it is also an expensive disease, and lays a burden on the rates. Medical inspection revealed the very significant fact that only 9·2 per cent. of the children were vaccinated. Malnutrition and dietetic errors are commented on in an illuminating way. Dr. Horsburgh says that he has found that often the pre-tuberculous (non-infective) child is better attending school than if he is excluded from it for long periods. Often these children are kept at home and allowed to sit indoors over the kitchen fire most of the day, so that they do not get as much fresh air as they would if they remained in school.

A special clinic for the treatment of crippling defects is run in coöperation with the Royal Orthopædic Hospital, Birmingham. Cases requiring hospital treatment are sent into Birmingham, and the maintenance of each case is arranged for by the committee according to the home circumstances. In discussing the coöperation of parents, it is pointed out that those who refuse any form of treatment—fortunately few in number—are more often fathers than mothers.

INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED NOV. 6TH, 1926.

Notifications.—The following cases of infectious disease were notified during the week: Small-pox 302 (last week 131), scarlet fever 1873, diphtheria 1108, enteric fever 43, pneumonia 1095, puerperal fever 60, puerperal pyrexia 169, cerebro-spinal fever 5, acute poliomyelitis 36, acute polio-encephalitis 4, encephalitis lethargica 49, dysentery 20, ophthalmia neonatorum 127. There were no cases of cholera, plague, or typhus fever notified during the week. The increased incidence of small-pox is explained by the report of 263 new cases from the county of Durham. Only 15 of these were notified fron the county boroughs of Gateshead and South Shields; 153 from 8 boroughs and urban districts (Brandon-and-Byshottles reporting 98 cases); and 95 from 6 rural districts (Lanchester reporting 49 cases).

Deaths.—In the aggregate of great towns, including London, there was no death from small-pox, 1 (0) from enteric fever, 11 (1) from measles, 8 (0) from scarlet fever, 18 (3) from whooping-cough, 40 (12) from diphtheria, 101 (24) from diarrhœa and enteritis under 2 years, and 88 (14) from influenza. The figures in parentheses are those for London itself.

THE LATE PROF. F. M. CAIRD.

THE following appreciation of Prof. Caird has reached us from an old pupil: "Your obituary notice recalls many of Prof. Caird's great qualities, but omits one of his greatest. All through his career he was distinguished for his wonderful and unfailing kindness to his juniors at all ages. To him went students with their surgical troubles and from his kindness and help there arose many a lifelong friendship. One student remembers with gratitude his first winter in Edinburgh when laid up with a damaged knee. Mr. Caird, as he was then, came daily for six weeks across the meadows to cheer up a rather lonely youth and to keep him well supplied with books—no small expenditure of time and trouble for a busy man on one who at first was a complete stranger—a stage quickly passed and merged into a friendship that lasted to the end. Dozens of men must remember that little room at the top of his house furnished partly with treasured chairs from the old Infirmary . . . . Here all were welcome and here everything on earth was discussed and thither one took one's joys for congratulation and one's sorrows for comfort, and always came away better."

A DUNLOP CHILDREN'S BED.—Through the Dunlop Hospital and Benevolent Fund the employees of the Dunlop Rubber Co. have endowed a cot in the Birmingham Children's Hospital at a cost of £1000. Between two and three years were occupied in raising the money, and it is hoped gradually to endow other beds in the hospitals of the city.

"Audi alteram partem."

HALOGEN ERUPTIONS WITH LESIONS ON THE TONGUE.

To the Editor of THE LANCET.

SIR,—It is pleasant to find that my short note on Halogen Eruptions in THE LANCET of Nov. 6th (p. 952) has called forth so interesting and informative a response from Dr. Parkes Weber. There is one point in the wording of his letter which, perhaps, I may be allowed to make more clear. His opening sentences might give the impression to anyone who had not read my paper that I had overlooked the case published by him in 1923, in which, as in mine, there was a lesion on the tongue. That, of course, is not the case, and I am sure that he had no intention of conveying such a meaning, because my words, which he quotes in full, were taken from an article published in 1906—that is, 17 years previously to the publication of his case. At the time that they were written, so far as could be ascertained from the then current literature, they were correct. No similar case in which the tongue was involved had been then recorded.

It is interesting to note that Dr. Weber looks upon defective renal elimination as playing a part in causing these fulminating outbreaks of iododermia after small doses of the drug. That, as I said in my note, was, for a long time my opinion, and it seems reasonable. Whether it does play any part or not it is evident from Dr. Semon's case that such a part is not essential, at least if defective elimination is to be estimated by the presence of albuminuria. Dr. Weber's concluding sentence raises a point of some historical interest. It is quite true, as he points out, that these rarer halogen eruptions have sometimes been diagnosed as syphilitic, and when this happened fuel in the form of further doses of iodide of potassium was promptly and hopefully added to the flames. This was, as he says, before the days of the Wassermann test. Perhaps it is hardly realised by the younger generation what changes this test has brought about.

Before its advent one of the most delicate and important functions which the specialist in dermatology was asked to perform, was to settle whether a given sore or rash was or was not of syphilitic nature. Some few dermatologists became extremely expert at this. They were quite as realiable in their decisions as are the most experienced connoisseurs in various branches of art, but like these they were occasionally deceived by clever imitations which was rather a serious thing to happen. The discovery of the spirochæte and the use of the Wassermann test have removed the supreme court of appeal for syphilis from the dermatologist's consulting-room to the laboratory of the pathologist, and in so doing have widened its sphere of influence in that cases can now be submitted for judgment not only where there is direct evidence on the skin or mucous membranes, but also where it is only indirect, as in lesions of the internal organs.

Science has here replaced art to the advantage of medicine. I am, Sir, yours faithfully,

Sheffield, Nov. 13th, 1926. ARTHUR J. HALL.

ASTRONOMY AND LETTERS.

To the Editor of THE LANCET.

SIR,—The review of Dr. J. H. Bridges's work and life, which appeared in your issue of Nov. 13th, emboldens me to draw attention to the curious inability of even scholars and well-educated writers to realise simple facts in astronomy. Bridges was a great social reformer, a scholar, and an eminently intelligent person, and yet I find that, besides making the slips which your reviewer pointed out, he made an extraordinary error as regards a star. On p. 140 of Mrs. Liveing's book I find a letter to his wife dated June, 1876, in which he speaks of a star to be chosen as especially hers.

"What shall it be? Not the red Arcturus which lifts itself up for a short space above the southern horizon at midnight and will be seen no more till summer comes again."

Bridges should have remembered his Hesiod, Works and Days, ll. 564–567.

Εὖτ' ἂν δ ἑξήκοντα μετὰ τροπὰς ἠελίοιο
Χειμέρι' ἐκτελέσῃ Ζεὺς ἤματα, δὴ ῥα τότ' ἀστὴρ
Ἀρκτοῦρος προλιπὼν ἱερὸν ῥοὸν Ὠκεανοῖο
Πρῶτον παμφαίνων ἐπιτέλλεται ἀκρονέφαιος.

And apart from that Arcturus can be seen both to rise and set about the middle of November. But the average writer seems to think that a star or especially the moon can be in any part of the heavens at any time of day or night, and at any season in the year which suits the convenience of the writer. The *locus classicus*, of course, is the passage in the first edition of "King Solomon's Mines," where Rider Haggard made an eclipse of the sun last for over two hours and that, too, on the day of the full moon. Another eminent and well-read living writer makes the full moon to be "just rising in the east" at a quarter before midnight in October in the south of England. As a variant on this another novelist has a fine descriptive passage

"Near the horizon line in the west the sun . . . . plunged precipitously downward. . . . . In the east a slender crescent shewed the moon at her birth!"

This, however, was on the west coast of Africa, where anything may happen and perhaps that is the reason why the author put a "!" after his statement. In future, however, we may hope that novelists and others will take pains to be more accurate, for one of the ablest novelists of to-day, Miss Rose Macaulay, has, with that devilish insight into human frailty which is so marked a characteristic of her work, said in "Crewe Train" p. 143, "Never mind, practically all novelists slip up now and then over the moon: it would be rather priggish and pedantic not to. The literary moon doesn't really matter." But after all, as an eminent analytical chemist and one whose life was spent on insisting on the value of essential accuracy, by name Sherlock Holmes, said, "What difference does it make to me or my work, whether the sun goes round the earth or the earth goes round the sun?"—I am, Sir, yours faithfully,

Nov. 15th, 1926. HIPPARCHUS JR.

GERMAN MEDICAL WOMEN.

To the Editor of THE LANCET.

SIR,—In last week's issue of THE LANCET your Berlin correspondent gives some figures regarding German medical women which appear to be based on insufficient knowledge or some misreading of the statistics. He states that there are 31 medical women in Munich, 15 in Frankfort, and *a total of* 327 *in all Germany*. For the correct figures and a very interesting analysis of them, I should like to refer him to an article entitled "Die deutsche Aerztin" in the last issue of the "Vierteljahrschrift deutscher Aerztinnen," the organ of the German Association of German Women Doctors which has already 626 members although it has not been in existence two years.

The real figures, based on the "Aerztliche Handbuch," would appear to be:

Large towns	943
Medium towns	279
Smaller towns and country	173
Total	1395

In Berlin alone there are 400, in Munich 84, and in Frankfort 31. The whole question of the irregular distribution throughout the provinces is an interesting one. Baden has the highest percentage of women doctors as compared with the population, and Upper Westphalia the lowest.

I am, Sir, yours faithfully,

L. MARTINDALE,
Hon. Sec., Medical Women's International Association.
Weymouth-street, London, W., Nov. 12th, 1926.

THE CLOSING OF UPPINGHAM SCHOOL.

To the Editor of THE LANCET.

SIR,—The notice taken—and very naturally—in the general press of the closing of Uppingham School prompts a direct communication to the medical profession.

We have not had any cases of infantile paralysis in the Uppingham district, but an outbreak has occurred in Leicester and a few cases were reported on the other side of that county earlier in the autumn. It is within my knowledge that a considerable number of these cases have been treated in general and private hospitals without special precautions, and I am informed that no direct infections have been traced. Two cases have occurred in Uppingham School.

CASE 1.—The boy was attending school on Friday, Nov. 5th, reported "seedy" that evening, was removed to the sanatorium on Saturday morning with no definite symptoms—he did not feel really ill, and was, indeed, keenly interested in an inter-school football match. But on Sunday at midday it was evident that the attack was severe, by 10 P.M. respiration was seriously interfered with, and death took place about 6 o'clock Monday morning.

Our helplessness in this case impressed my colleagues, Drs. F. H. Wallace and A. R. Beaumont, as much as myself, and we resolved that in event of another case occurring we would employ mercurochrome as a remedy against the acute hæmic infection.

CASE 2.—The second boy was in morning and second school on Friday, Nov. 12th, returned to his house about 11 A.M., and was seen by me at 11.30, when he looked very ill, temperature 102·8° F., pulse 140, respirations 50. He was removed to the sanatorium, all the symptoms pointing to the general invasion stage of infantile paralysis—and a severe invasion it was. An intravenous injection of mercurochrome, calculated on the body-weight, was given; the patient was encouraged to drink large quantities of water and home-made lemonade. Within a few hours there was obvious improvement, pulse and respirations slowed down, and what had looked a really bad attack has not since given rise to grave anxiety.

To-day (16th) the boy is convalescent—no paralysis yet appeared; his knee-jerks are very dull—at one period they were absent; a very considerable experience of Kernig's sign during a cerebro-spinal epidemic in war-time did not impress me with its value in diagnosis.

Although I am not convinced of the patient-to-patient infection theory, on our Case 1 appearing the boy's house was isolated, arrangements were made forthwith for the *entire* servants, master, and school population to gargle and sniff a pot. permanganate solution. Now with reference to the closing of the school for 16 days we have been criticised. That is not unexpected particularly in a disease where the pathology is so vague that most conclusions are in the nature of guesses.

A circular letter was sent to parents by the headmaster after the first case. There was no panic amongst them and only four boys went home from the isolated house, though the parents urged that, as the boys were not working, their quarantine might well be spent at home. It was evident from some of the letters that in event of another case parents would demand the return of their boys in many instances.

There are 13 boarding-houses connected with Uppingham School and they are widely scattered. Some of them are in the High-street and open directly on to the street—the town is permeated by the school. Isolation of the school would be impossible; the conditions existing at Uppingham have no relation to any that might occur either in a preparatory school or in great schools where the school is itself a unit. I, am, Sir, yours faithfully,

W. DUNN, M.B.,
Nov. 16th, 1926. M.O., Uppingham School.

PS.—The letter sent by the headmaster to the parents was as follows:—

School House, Uppingham, Nov. 12th, 1926.

DEAR SIR,—A second case of infantile paralysis has occurred, and I have therefore decided to disband the school for a fortnight and two days. The incubation period is from 4 to 14 days, and although there is small risk that your boy has the infection upon him, he ought to be carefully observed until the period is over. Unless you hear to the contrary, the school will reassemble on Monday, Nov. 29th, and the term will end on Thursday, Dec. 23rd. I much regret any inconvenience to which this may put you. It is requested by the Minstry of Health that the medical officer of health of your district be informed of the reason of your boy's return from school. Yours sincerely,

R. H. OWEN.

PROF. CÉSAR ROUX'S RETIREMENT.

AFTER 39 years of active service as director of the Surgical Clinic and professor of surgery at the University of Lausanne, Dr. César Roux has retired. Born in 1857, Roux retained until his seventieth year the vigour and energy of youth, the Canton of Vaud raising the age-limit expressly on his behalf. Roux was the first pupil of Theodor Kocher, when the latter was appointed very young to the chair of surgery at Berne. The pair have been called the "old masters" of Swiss surgery, each being endowed with the qualities suited to the part of Switzerland, German or French speaking, in which he worked. Roux came from Orbe, a little village lying among vineyards on the slopes of the Jura, and was a true son of his beloved Pays de Vaud. During his strenuous life he instructed several generations of surgeons, and his pupils are now scattered over the whole country. The number of patients on whom he operated each year averaged something over 1500, and there is no Vaudois village between Vallorbe and Aigle which does not contain citizens, young or old, who owe their lives to him. His fame spilt over into surrounding countries, and few surgeons have had such an international clientèle. A Swiss correspondent writes: "Visitors to Roux's clinic, and they were many, were amazed at his ceaseless energy. From the moment he began to lecture at 8 A.M., until he finished operating at 1.30 P.M., he never ceased to talk or to be the driving power of the whole machine. Courteous, imperturbable, stimulating to his colleagues and students, and almost worshipped by the townspeople, he was fond of recalling the difficulties of his early boyhood, when his peasant parents lived and worked in the sunny front room of the hillside chalet, the children living as best they could in the cold, dark, airless room facing the hill behind. But there were always the warm cows to sleep with." When the surgeons of to-day were boys at school Roux was already one of the giants of surgery, a man whose name will live beside those of Lister and Kocher.

Medical News.

UNIVERSITY OF CAMBRIDGE.—Sir Humphry Rolleston, Regius Professor of Physic, has been elected as the representative of the University on the General Council of Medical Education for five years, in place of Dr. W. L. H. Duckworth, resigned.

At a congregation held on Nov. 13th, the following degree was conferred:—

M.B.—F. R. Sandford.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—At an ordinary meeting of the Council, held on Nov. 11th, the President, Sir Berkeley Moynihan, stated that the vacancy on the Board of Examiners in Dental Surgery, occasioned by the death of Mr. Douglas Gabell, would be filled at the ordinary meeting of Council in December; that the vacancy on the Court of Examiners, occasioned by the resignation of Mr. Herbert S. Pendlebury, would be filled at the same time, and that two additional members of the Court would also be elected.—Alterations in Sections IV., VIII., XX., XXV., and XXVI. of the by-laws were approved. and the solicitor to the College was instructed to submit the new by-laws to the proper authorities for sanction and ratification.—A letter was read from Sir W. Morris Carter, offering to the College, in accordance with the instructions left by will, a portrait by Mr. W. W. Ouless, R.A., of the late Sir Henry Morris, Bart., past-President of the College. The portrait was gratefully accepted.—Diplomas of M.R.C.S. were conferred upon 179 candidates (155 men and 24 women)

who have passed the final examinations of the Conjoint Board. Their names have already been published in THE LANCET (Nov. 6th, p. 981).

The Secretary reported the death, on Nov. 4th, at the age of 69, of Mr. James Ernest Lane, past member of the Council and of the Court of Examiners. The following vote of condolence was passed: "The Council hereby express their deep regret at the death of Mr. James Ernest Lane and their sincere sympathy with his widow and relatives in their bereavement. Mr. Lane's services to the College as an examiner and as a member of the Council are remembered with appreciation, and since his retirement, his long illness, borne with patience and fortitude, has been a matter of sympathetic concern to his friends and former colleagues on the Council."

AMERICAN COLLEGE OF SURGEONS.—At the end of the clinical congress on Oct. 29th honorary Fellowships of the College were bestowed on Prof. Archibald Young, Sir Ewen Maclean, Prof. John Fraser, and Prof. David Wilkie.

ROYAL SOCIETY OF TROPICAL MEDICINE AND HYGIENE.—At a dinner to be held at the Hotel Victoria on Monday, Nov. 22nd, at 7.30 for 8 P.M., Lord Balfour will be the principal guest, and Dr. Andrew Balfour, President of the Society, will take the chair.

NO. 14 STATIONARY HOSPITAL, B.E.F.—The annual dinner of this hospital will be held on Friday, Dec. 10th, at the Trocadero Restaurant. Any members of the mess who have not received a notice and desire to attend should communicate with Major H. L. Tidy, 39, Devonshire-place, London, W.1.

BRITISH LEGION: BRITISH SERBIAN BRANCH.—The annual re-union dinner will be held on Saturday, Dec. 4th, at 7.15 for 7.30 P.M., at the Victoria Mansions Restaurant, 24, Victoria-street, Westminster, with Sir James Berry, the President, in the chair. All who served in Serbia are invited, together with their friends. Tickets may be had from Miss Marx, the honorary secretary, 24, Melcombe-court, Dorset-square, London, N.W.1.

THE LATE DR. SMITH WYNNE.—Dr. Graham Smith Wynne, whose death was announced recently, was born at Norwich of an old Norfolk family and was educated at St. Bartholomew's Hospital He qualified as M.R.C.S., L.R.C.P. in 1901, and after holding a house appointment at the Huntingdon County Hospital, settled in Amersham where he became medical officer to the Penn and Coleshill district. Dr. Wynne was a keen yachtsman and was 50 years of age. He leaves a widow.

NEW BRUNSWICK AND THE MEDICAL REGISTER.—On Nov. 5th the King in Council directed that "Whereas the Province of New Brunswick no longer affords to the registered medical practitioners of the United Kingdom such privileges of practising in the said Province as to His Majesty seem just," the Province shall no longer be deemed a separate British possession to which the Second Part of the Medical Act of 1886 shall apply. Practitioners registered in New Brunswick thus lose the right to enter their names on the British Register. Any persons, however, whose names have already been entered will not be affected by the change.

THE LATE DR. T. D. PATMORE.—Dr. Tennyson Deighton Patmore, who died recently at the age of 76, was the son of Coventry Patmore, the poet, and of his first wife, Emily Augusta Andrews—"The Angel in the House"—who died in 1862, leaving six children. Dr. Patmore went to University College Hospital and qualified as M.R.C.S. in 1875, later taking the L.R.C.P. Lond. and D.P.H. Camb. For many years he was medical officer to Wormwood Scrubbs Prison and assistant surgeon to Woking Male Convict prison. Later he acted as medical officer at the head office of the Ocean Accident and Guarantee Corporation. Besides numerous yearly prison reports, Dr. Patmore wrote on Malingering and Feigned Diseases for medical dictionaries, and various articles in medical journals.

ROYAL SUSSEX COUNTY HOSPITAL.—In June, 1928, this hospital at Brighton will celebrate its centenary. To mark the event the governors have decided to extend the nurses' home, to provide new accommodation for the domestic staff, to carry out urgently needed structural alterations to the existing main buildings, and to provide accommodation for an additional 50 or 60 in-patients. The cost is estimated at £102,000, and in response to an appeal launched by Lord Leconfield, President of the hospital, on Oct. 27, some large donations have already been received. The increased size of the hospital will involve increased expenditure, and it is hoped also to secure an additional £10,000 a year to meet it. Annual subscriptions at present amount to only £4,300, which leaves about £25,000 a year to be found from payments by patients, by donations and by other voluntary efforts.

PRESENTATION TO A MEDICAL MAN.—The Committee and friends of Yeovil and District Hospital have presented Dr. C. J. Marsh, who has been its honorary surgeon since 1880, with a bust of himself, by Mrs Mitchell, A.R.B.A.

UNIVERSITY OF BIRMINGHAM.—Dr. T. L. Hardy has been appointed assistant to the chair of medicine, and Dr. C. C. W. Maguire hon. demonstrator in the department of anatomy. The Council has decided to ask the Court to confer the title of Emeritus Professor upon Prof. O. J. Kauffmann, joint professor of medicine in the University from 1913 to 1926.

ROYAL SOCIETY.—The King has approved awards by the President and Council of Royal Medals to Sir William Hardy, F.R.S., for his work on colloidal chemistry and the theory of lubrication, and to Prof. A. V. Hill, F.R.S., for his work on the physical and chemical aspects of muscular contraction. The President and Council have awarded the Copley Medal to Sir Frederick Gowland Hopkins, F.R.S., for his work in biochemistry.

PRINCE OF WALES'S HOSPITAL.—The annual dinner of the Reunion Association will be held at the Trocadero Restaurant, London, on Friday, Nov. 26th, at 8 for 8.15 P.M. Mr. J. B. Banister will take the chair. The price of the dinner will be 12*s.* 6*d.* (exclusive of wines) for members and their guests. The secretaries are Dr. Browning Alexander, 143, Harley-street, W. 1, and Dr. S. O. Rashbrook, 7, Wellesley-road, Chiswick, W. 4.

THE LATE DR. WILLIAM HOSEGOOD.—Dr. Hosegood, who died on Oct. 25th at the age of 65, was medical officer of health for the Cannock Rural District, where he had spent nearly 45 years. He was an Edinburgh man and graduated at Edinburgh University in 1881. For a time he served as medical officer of health at Amersham in Buckinghamshire, and then, going to Cannock, built up a large practice in the Cheslyn Hay district. Dr. Hosegood took a warm interest in local affairs and was a keen cricketer. He leaves a widow and several children.

VICTORIA BUSH NURSING ASSOCIATION.—The report of the Bush Nursing Association of the State of Victoria shows that at the end of June last there were 52 nursing and hospital centres at work. The centres are all run on the coöperative basis which experience has proved to be the best method of administering a Bush Nursing Centre. A householder pays an annual subscription varying from £1 to £3 10*s.*—the usual amount is 30*s.*—and for that sum obtains nursing for himself, his wife, and children up to the age of 18. The most important part of the work is midwifery and the care of infants and children.

BRIGHTON AND SUSSEX MEDICO-CHIRURGICAL SOCIETY.—At a meeting of this Society, with Dr. E. Rivaz Hunt, the President, in the chair, Mr. H. N. Fletcher showed specimens of pancreatic tumour and an enlarged mesenteric cyst, also microscopical slides, after which Dr. L. A. Parry gave an address on Some Well-known Medical Criminals less widely known than Palmer, Pritchard, and Lamson. His first example was a local one, that of Dr. Warder, of Brighton, who in 1866 poisoned his wife by means of aconite, and then, when suspicion was aroused, himself took prussic acid. Two previous wives had died under suspicious circumstances, and there is very little doubt that he also poisoned these. The Brighton case aroused very considerable interest at the time. Dr. Alfred Swayne Taylor, who analysed the viscera, said he was unable to find any poison at all, although he had carefully tested for all the well-known alkaloids, including morphia, strychnia, and aconitine, and that injections from the organs into a rabbit had had no harmful effect. Yet after hearing the medical evidence of the deceased's doctor, he was of opinion that aconite poisoning was the cause of death. The jury returned a verdict to that effect. Dr. Warder had been a lecturer on forensic medicine at the Grosvenor-place School, adjoining St. George's Hospital, and had come forward to give evidence in favour of Palmer. Among medical men who had been charged with high treason he alluded to Dr. Watson, acquitted for complicity in the Cato Street conspiracy; Dr. Bateman, hanged by Judge Jeffreys after the Battle of Sedgemoor, and in particular to Dr. Archibald Cameron, who took part in the Jacobite Rebellion of 1745, as medical officer in charge of troops. After the Battle of Culloden Cameron escaped to France, and when most of those who had taken part in the rising were pardoned, an Act of Attainder was passed, excluding certain persons from this indemnity, and Cameron, who was actively instrumental in the escape of Prince Charles, was among those named; when eight years later he returned to his native land, he was arrested and hanged as a traitor.

Parliamentary Intelligence.

HOUSE OF LORDS.

THURSDAY, NOV. 11TH.

Lead Paint Poisoning Bill.

Lord DESBOROUGH, in moving the second reading of the Lead Paint (Protection Against Poisoning) Bill, said that it dealt with a matter which had long exercised those who were interested in the welfare of persons engaged in this industry. Owing to the poisonous effect of the lead paint there was no doubt that it had to a certain extent damaged those who had had to use it. It was not denied that there was a very large number of cases which required amelioration, and that made the Government all the more determined, if possible, to pass this Bill into law as soon as they could. The opposition to the measure came from those who criticised it because the Geneva Convention had not been ratified. But he would point out that in any case, even if the Geneva Convention were ratified, the men would still require the protection which they hoped would be afforded them by these regulations. The Government did not intend to postpone indefinitely the other and bigger question, but in their view it would be impossible, owing to the state of public business and the very large opposition which existed in many quarters, to pass before Christmas a Prohibition Bill. Since the discussion took place at Geneva new methods, such as the use of waterproof sandpapers, had been devised, which enabled wet-rubbing to be done instead of dry-rubbing, and that would make the work much safer than it was at present.

Lord ARNOLD said that he regarded it as a very serious thing that the British Government should have broken the agreement come to at Geneva. It was not correct to say that the Government could not pass a Prohibition Bill. The Government had a majority of 200 in the House of Commons, and of about 70 in their lordships' House, and moreover the Opposition in the Commons would have supported a Bill which ratified the Geneva Convention. When other countries who signed the Convention found out that we had gone back on our word, they might also refuse to carry out their bargain, and this would make it more difficult to pass a Prohibition Bill in the future. He was informed that the process of wet-rubbing would do little or nothing to mitigate the evil.

Viscount HALDANE said that the Bill as far as it went would make things better, and he assumed that it represented what the Government considered to be the minimum required for safety. Women were not to be allowed to work at the industry, even on the new footing on which the Bill proposed to put it. He would be glad if the Government would give them a little more information on the question why women were supposed to be more susceptible to plumbism than men. He had read, of course, the statements made in the House of Commons by the chief medical officer and others, but those were very general statements, and were very vague. Nothing had impressed him more for a long time than the danger of accepting perfectly general medical statements of this kind without reasons which had been investigated being given. He confessed that he was sceptical on the subject, and he would like to know the scientific grounds on which statements to this effect were supported. He thought the Government ought to refer a question of this kind to the Committee of Civil Research, or some other body.

Lord BALFOUR of BURLEIGH said he was glad to hear what had fallen from Lord Haldane, because he was going to state his intention of moving an amendment in Committee that the exclusion of women should be omitted from the Bill. He knew that there were certain medical reasons which had become almost a dogma in the medical profession that women were more susceptible than men, but he would like to reinforce what Lord Haldane had said, and ask on what authority the statement was made. The exclusion of women meant that women's labour was forced to remain unorganised, and women were prevented from attaining in industry a position which both from the point of view of men and women it would be much better that they should occupy.

The Bill was read a second time.

HOUSE OF COMMONS.

WEDNESDAY, NOV. 10TH.

Naphtha and Safety of Dock Workers.

Colonel DAY asked the Home Secretary if his attention had been drawn to the dangers incurred by dockers engaged in unloading foreign coal owing to the presence of naphtha in such cargoes; and whether any action had been taken, or was contemplated, with a view to the safety of worker so employed.—Sir W. JOYNSON-HICKS replied: Special inquiry has been made, but no evidence of such danger is forthcoming.

THURSDAY, NOV. 11TH.

Coroners and Deaths by Burning.

Dr. HADEN GUEST asked the Home Secretary whether his attention had been directed to the verdict of the coroner's jury on the deaths by burning of Mr. and Mrs. Rook and their infant child at a fire at No. 6, Borough-road, on Oct. 2nd this year; and whether he would consider the advisability of amending the Coroners' Bill by making the provisions of the City of London Fire Inquest Act applicable to the whole country, with a view to the adoption of methods of more efficient fire protection.—Sir WILLIAM JOYNSON-HICKS replied: The answer to the first part of the question is in the affirmative. The second part of the question appears not to arise, for it is already the duty of coroners everywhere in England and Wales to hold inquests on bodies of persons killed by fires.

Lead Poisoning in the Potteries.

Mr. RHYS DAVIES asked the Home Secretary whether his attention had been called to three serious cases of lead poisoning in one factory in the potteries during 1926 affecting young women aged 19, 23, and 24 respectively, one proving fatal; and what steps he proposed taking with regard to the use of lead in this factory in future.—Sir WILLIAM JOYNSON-HICKS replied: The three cases referred to occurred in a factory in which until this year no case of lead poisoning had been reported since 1913, about which time the factory was reconstructed; but it appears that recently the system of exhaust ventilation has not been maintained in an efficient state, and the matter has been actively taken up by my Department.

Housing Statistics.

Mr. TREVELYAN THOMSON asked the Minister of Health how many houses had been completed to date under the various Housing Acts, and how many were at present under construction, giving separate figures for municipal and private enterprise.—Sir KINGSLEY WOOD (Parliamentary Secretary to the Ministry of Health) replied: Up to the 1st ultimo the latest date for which figures are available, the number of houses which had been completed in England and Wales with State assistance under the various Housing Acts were 270,406 by local authorities, and 196,465 by private enterprise. The numbers under construction under the housing Acts on Oct. 1st were 58,294 and 45,217 respectively.

Infantile Paralysis.

Captain FAIRFAX asked the Minister of Health if he had any further statement to make on the progress recorded in dealing with the recent outbreaks of infantile paralysis in this country.—Sir KINGSLEY WOOD replied: My right hon. friend is glad to say that the number of cases of infantile paralysis notified in Broadstairs and Leicester during the past two weeks was only 15, as compared with 54 in the previous fortnight. There were no fresh cases in Broadstairs last week. He would like to take this opportunity of stating that infantile paralysis is a disease which has been prevalent in this country for many years. It is one of a group of epidemic nervous diseases of which our knowledge is still very imperfect, but research is being prosecuted and it is hoped that means will be discovered which will lead to the exercise of more effective control over its spread. His Department has closely watched the outbreaks, and a specially skilled member of his staff has visited the areas most affected to assist the local authority in providing for the supervision and control of the outbreaks.

Mr. EVERARD asked the Minister of Health the number of cases of infantile paralysis that have occurred each month since May last; and whether he had any further information regarding the cause of the disease.—Sir KINGSLEY WOOD replied: The number of cases of infantile paralysis (acute poliomyelitis and acute polio-encephalitis) notified in England and Wales each month since May last is as follows:

Notifications of Acute Poliomyelitis and Acute Polio-Encephalitis.

	A.Pm.	A.Pe.		A.Pm.	A.Pe.
May	18	3	August	148	16
June	29	3	September	215	7
July	56	7	October	319	54

Miners' Dependents and Relief.

Sir ALFRED KNOX asked the Minister of Health the average weekly relief paid by Poor-law guardians to the wives and children of miners during the coal stoppage and how these amounts compared with the relief granted in former trade disputes.—Sir KINGSLEY WOOD replied: The exact figures sought by my hon. friend are not available but it is estimated that in areas directly affected by the dispute in the coal-mining industry the expenditure on outdoor relief increased from May to October by an amount

equal to an average weekly expenditure of £223,000. In the same areas during the dispute of 1921 the average additional weekly expenditure is estimated to have been £65,400.

Approved Societies and Dental Benefit.

Mr. RHYS DAVIES asked the Minister of Health whether his attention had been called to the increased charges on the surplus funds of approved societies consequent upon the new agreement covering dental benefit; whether he was aware that a number of approved societies declined to operate the agreement because of those increased charges; and whether he would take steps with a view to removing the present impasse.—Sir KINGSLEY WOOD replied: The new agreement as to the scale of charges and conditions of service for the dental treatment of members of approved societies was arrived at by direct negotiation between representatives of the societies and of the dental profession with a view to securing a thoroughly satisfactory service. The new scale does involve some increased charge on the surplus funds of societies above that which would have arisen under the scale previously in operation, but the great majority of societies take the view that the additional advantages to be secured under the new arrangement justify the extra cost. My right hon. friend is aware that a few societies, representing a very small fraction of the total insured population, have not yet decided to adopt the new scale, but he does not think that the position calls for any special action on his part at the present time.

Replying to a further question by Mr. Rhys Davies, Sir KINGSLEY WOOD said: I have no reason to apprehend for a moment that the other societies which represent, I think, about 87 per cent. of the people insured, are likely to alter the existing arrangement to which their representatives agreed.

Mr. BLUNDELL: May I ask whether the hon. gentleman is aware that dentists are following in the footsteps of the doctors, and that unless some steps are taken, they may in very many cases obtain a rate of remuneration out of proportion to the services rendered?

Sir KINGSLEY WOOD: I have noticed it argued that both approved societies and members of the dental profession think that they have made a bad bargain. In these circumstances I am rather inclined to think that the arrangement is a fair one.

Deposit Contributors to Health Insurance.

Mr. NEIL MACLEAN asked the Minister of Health the number of Post Office contributors there were to the National Health Insurance; whether there were any surplus funds; and whether any special benefits were being provided to the contributors.—Sir KINGSLEY WOOD replied: The number of deposit contributors in England, Scotland, and Wales at the present time is about 271,000. The Deposit Contributors' Fund is made up of the sums standing to the credit of the individual deposit contributors, and there are, therefore, no surplus moneys in the Fund. The benefits to which a deposit contributor is entitled are the ordinary benefits under the National Health Insurance Acts so far as the balance to the credit of the contributor is sufficient to cover the cost of the provision of such benefits.

Producers and the Milk and Dairies Order.

Brigadier-General CLIFTON BROWN asked the Minister of Health whether he was aware that the Milk and Dairies Order, 1926, was causing many small milk producers in country villages expense which they could not afford, and that they must close down businesses which in some cases they had carried on without any complaint from sanitary authority for 30 years; and whether he would empower the local authorities in such cases to pay some compensation or grant an extension of time in which they must comply with the new orders.—Sir KINGSLEY WOOD replied: My right hon. friend has not heard of any such complaints, and he thinks that the producers to whom my hon. and gallant friend refers must be under some misapprehension as to the terms of the Order. Article 1 of the Order allows a considerable period of time to elapse before any of the provisions which involve any financial outlay become operative.

Dumping Refuse in Lower Thames Area.

Mr. LOOKER asked the Minister of Health whether he proposed to take any action to put an end to the practice of dumping refuse in the Lower Thames area, particularly as regards the dumps now existing at Purfleet and Tilbury and the new dump at Purfleet now in course of construction.—Sir KINGSLEY WOOD replied: As I have informed my hon. friend, these dumps have recently been inspected, and the inspection did not disclose that they are a menace to health. At the same time I may say that the general question of the collection and disposal of London refuse and the practicability of making improvements is the subject of detailed investigation at the present time, and in connexion with the investigation the dumps referred to are being kept under observation.

Out-relief to Miners' Dependants in Scotland.

Mr. JOHNSTON asked the Secretary of State for Scotland in what districts the payment of out-relief to miners' wives and children had been stopped; whether he was aware that there was serious privation in many districts; and whether he would take immediate steps to communicate with the authorities in those areas which had ceased to pay out-relief, with a view to a resumption of such payments.—Sir JOHN GILMOUR replied: I am sending the hon. Member a list of twenty-seven parish councils that have, according to the information in the possession of the Board of Health, passed resolutions to stop relief. Notwithstanding these resolutions, many of these parish councils have instructed the Inspector of Poor to give relief, where necessary, to prevent injury to health through destitution, while, in the remaining parishes in the list, the Board have advised the Inspector of Poor as to his duty to prevent injury to health. So far as the Board are aware, the Inspectors of Poor are acting on this advice, and the parish councils concerned are acquiescing. The Board are in close touch with the whole situation, and inquiries are made forthwith into any cases of hardship brought forward. No acute destitution is believed by the Board to exist, but any specific instances which the hon. Member cares to submit will be investigated.

MONDAY, NOV. 15TH.

Disability Pensions for Encephalitis Lethargica.

Mr. ROBERT MORRISON asked the Minister of Pensions whether any disability pensions were being paid in respect of encephalitis lethargica (sleepy sickness) due to war service.—Lieut.-Colonel G. F. STANLEY (Parliamentary Secretary to the Ministry of Pensions) replied: The reply is in the affirmative. I regret, however, that the statistical records of the Ministry do not enable me to state the precise number of cases.

Steel Houses in England.

Sir FRANK MEYER asked the Minister of Health the number of steel houses of different types that have been erected in England, and the number at present inhabited.—Sir KINGSLEY WOOD replied: The number of external steel or cast iron houses, the erection of which has been authorised in England and Wales, is 993, excluding those erected for demonstration purposes. Information is not available as to the number of these houses actually erected or inhabited.

Government and Lunacy Commission's Report.

Sir WILLIAM DAVISON asked the Prime Minister whether the Government proposed to introduce legislation to give effect to the findings of the recent report of the Royal Commission on Lunacy.—Mr. NEVILLE CHAMBERLAIN replied: The report of the Royal Commission is receiving careful consideration, and, until the recommendations have been examined in all their bearings, it is not possible to indicate the nature and extent of any legislation which the Government may be able to introduce.

Nursing Homes Committee's Report.

Mr. GERALD HURST asked the Minister of Health whether he had considered the report of the Select Committee on Nursing Homes; and if he intended to initiate legislation next session with a view to adopting its recommendations.—Mr. NEVILLE CHAMBERLAIN replied: The report is now under consideration, but I am not yet in a position to make any statement in regard to legislation to give effect to the Select Committee's recommendations.

TUESDAY, NOV. 16TH.

Distress in the Mining Districts.

The House went into Committee of Supply on a supplementary estimate of £3,250,000 for relief arising out of unemployment. Mr. J. F. HOPE, Chairman of Committees, was in the chair.

Sir KINGSLEY WOOD (Parliamentary Secretary to the Ministry of Health), in introducing the vote, said that statements had been freely made that starvation existed in certain areas of the country. While a dispute such as that which had been in progress in the mining industry involved, of necessity, discomfort and hardship, the officers of the Ministry of Health, who had throughout been instructed to keep in close touch with the situation, had been unable to find cases in which the guardians or their officers had failed to relieve destitution. The general effect of their information, so far as children were concerned, was that they were better off and healthier than when their fathers were at work.

Viscountess ASTOR said that when the mining dispute began she went all over Wales to see whether the children were starving. She had not found a single case of starvation. Harm was done by mis-statement of the case for the miners and their dependants. The truth was that many of the children under 5 years of age were being under-nourished and that was a tragic thing. Nearly 50 per cent. of the children under 5 years in Monmouthshire were under-nourished. Another real hardship was the children's lack

of boots and clothes. She hoped that when the strike was over there would be a non-party movement by the women of England to help the children to get boots and shoes.

Miss LAWRENCE moved to reduce the vote by £100.

Miss WILKINSON said that the statement that in the mining areas the children were better fed than when their parents were at work was an extraordinary falsehood with a veneer of truth. There was this modicum of truth in it, that where there were Labour boards of guardians, the proportion which was to be spent in food was higher than when the fathers were at work. But none of the other expenses of the household were being paid. There was nothing for clothes, boots, or any of the other necessaries of life.

Mr. BUCHANAN, referring to Lady Astor's remark that there was no privation or starvation among children, said that his brother, who practised as a doctor in a neighbouring division of Glasgow, said—and this would be borne out by other medical men there—that the housing conditions were scandalous and required radical and desperate treatment. Worse than the housing conditions, at present, was the underfeeding and actual privation that were prevalent in Glasgow. The Scottish Board of Health had issued a circular, as a result of which the parish councils had discontinued the payment of the extra 4s. which they had been giving. The parish council doctors found, when they went into the homes of the poor and examined the children, that they did not require medicine, but that they were in need of food. He personally knew of cases of starvation in his own division.

Viscountess ASTOR asked for the names and addresses of the people said to be starving.

Mr. BUCHANAN said that if Lady Astor would go to his division he would show her scores of people who were starving.

Viscountess ASTOR said that Mr. Buchanan had no right to make such assertions unless he could prove them.

Sir J. GILMOUR (Secretary of State for Scotland) said that it had been represented to him that there had been cases of starvation in Scotland. He had asked repeatedly for the names and addresses of any individuals in such a condition and had ordered investigations to be made by the staff of the Scottish Board of Health. He was satisfied that, apart from any question as to whether individuals were getting a sufficient amount of certain constituents in their food, so far as actual starvation was concerned no such cases had been substantiated. It had been represented to him that medical men had found, when called in to attend certain children, that what was required was not medicine, but nourishment. It was within the province of medical men to give a prescription for nourishment. If failure to do that had taken place, and it was within the knowledge of any Member, he asked that the cases should be brought to the notice of the Scottish Board of Health. Throughout the whole of the dispute in the coal industry the one object of the Scottish Office had been to see that food and other relief was provided where needed, and particularly for children. As a matter of fact, in spite of the dispute, there had been an improvement in the health of Scottish children. The allegation of starvation was utterly unfounded.

Mr. MAXTON said that probably there was no starvation in the highly technical sense of the word, as used in the State departments. But that there was serious hardship among Scottish children, arising from lack of food and clothes, and from malnutrition and physical deterioration, was beyond all doubt.

Mr. NEVILLE CHAMBERLAIN (Minister of Health), replying to the debate, said that on the whole the boards of guardians deserved the highest possible credit for the way they had handled a difficult situation. It had been surprising to read in the newspapers suggestions that the Ministry had been responsible for a policy of starvation, for it might not unfairly be said that the coal strike had been financed by the boards of guardians. Taking the 78 unions, in which 80 per cent. of the miners were comprised, the average weekly domiciliary relief given during the 1921 strike was £94,000. In the same unions, during the present stoppage, the weekly total was £312,000. How, then, was it possible to say that the policy of the Ministry was to cut down relief? It was a fact that there had been no evidence of malnutrition and there had been repeated reports that the children were actually better fed than they were when their fathers were at work. There must necessarily be hardship and suffering when one of the basic industries of the country had ceased to work. While there were administrative difficulties in the way of boards of guardians providing boots for necessitous children, he had told a deputation that he was sympathetic, and that he would be prepared to consider applications from boards of guardians to make some provision, to a limited extent, to voluntary organisations, where they existed, for providing boots for children. It was not a possible solution of the problem of necessitous areas to finance guardians by way of grants, as had been suggested by Labour speakers. By a system of block grants, when it was possible to allocate them on a fair and prope basis, taking into account not merely population, but als capacity to pay, as measured by rateable value, it might b possible to devise a scheme which would bring relief t necessitous areas without doing injustice to any othe part of the country. That was the policy to which he looke forward for a permanent solution of the problem. He wa only awaiting an opportunity to put that policy into effect

The motion to reduce the vote was defeated by 215 vote to 81, and the vote was agreed to.

Disease among British Troops in India.

Mr. DAY asked the Secretary of State for War the personne of the committee recently appointed by the Army headquarter at Simla to investigate the steps to be taken to comba disease among British troops in India.—Earl WINTERTO replied: A committee was assembled in Simla in Octobe last to consider whether any modification in policy in com bating venereal disease among British troops was desirabl in the light of experience during recent years. The com mittee was composed of officers commanding the 2n Battalion Lancashire Fusiliers and the 2nd Battalio Lincolnshire Regiment, the chaplain to Metropolitan, consulting dermatologist at Army headquarters; the deputy director, personal services, at Army headquarters; and th deputy-assistant adjutant-general at Army headquarters The report of the committee is now under the considera tion of the Commander-in-Chief.

Encephalitis Lethargica.

Captain FAIRFAX asked the Minister of Health if he woul give the latest available figures for the cases of and deaths fron encephalitis lethargica, and state what progress had bee made in arresting this disease or investigating its causes.— Sir KINGSLEY WOOD replied: The total number of case of encephalitis lethargica notified in England and Wale during the present year up to Nov. 6th was 1946, and th approximate number of deaths up to the end of Augus was 935. As regards the second part of the question my hon. friend understands that the Medical Researc Council will shortly publish a report on this disease con taining a statement of the progress which has been made i the search for its cause. Until this has been discovered and means have been devised for controlling the develop ment and spread of the disease, it is necessary to rely o those methods which have proved efficacious in dealing wit other infectious diseases.

Infantile Paralysis in Leicester and Broadstairs.

Captain FAIRFAX asked the Minister of Health how man deaths had resulted from the outbreaks of infantile paralysi in Leicester and Broadstairs.—Sir KINGSLEY WOOD replied I would refer my hon. and gallant friend to the reply which I gave on this subject on Oct. 25th last. There have been no further deaths from infantile paralysis in Leicester since that date, but three more deaths have occurred as a result of the Broadstairs outbreak.

New Officials in the Ministry of Health.

Lieut.-Colonel HORLICK asked the Minister of Healt how many new officials had been appointed by his depart ment since Jan. 1st, 1926, how many were established and what would be the total salaries payable for the present financial year as compared with 1920.—Mr. NEVILLE CHAMBERLAIN replied: 491 new officials have been appointed in my department since Jan. 1st, 1926, of whom 423 are established. The total amount provided for salaries in the estimates for my department for the current financia year is £1,466,214, as compared with an expenditure o £1,915,547 for the financial year 1920–21.

DONATIONS AND BEQUESTS.—Mr. Thomas Martin, Pollokshields, Glasgow, left £2000 to the Royal Hospital for Sick Children, Glasgow, to endow a "Margaret Inglis Sim" cot and £100 to name a cot the "Thomas Martin" cot, £1000 to the Glasgow Royal Cancer Hospital, to be used especially for research work, £1000 to Biggart Hospital Home, Prestwick, to endow and name the "Margaret Inglis Sim" cot, £500 to the Glasgow Poor Children's Fresh Air Fortnight, and Cripple Children's League, £1000 (or such sum as may be required) to the West Highland Cottage Hospital to name the "Margaret Inglis Sim" bed, and the residue of the property, subject to other legacies and certain annuities, in equal shares to the East Park Homes, Glasgow, the Maternity Hospital, Glasgow, and the Samaritan Hospital, Glasgow.—Mr. Samuel Murphy, Colinton, Edinburgh, solicitor, left £1000 each to Chalmers Hospital, Banff, Edinburgh Royal Infirmary, Edinburgh Hospital for Sick Children, the Hospital at Newington House, Edinburgh, for Blinded Sailors and Soldiers, and the Edinburgh Blind Asylum.

The Services.

ROYAL NAVAL MEDICAL SERVICE.

Surg. Comdrs.—G. G. Vickery to *President*, addl., for three months' post-graduate course; F. G. Hitch to *Marshal Soult*; A. E. P. Cheesman to *President*, addl., for course; A. C. Paterson to *Victory*, addl., for Haslar Hospl., temp.; and M. W. Haydon to *Tiger*, on recommg.

Surg. Lt.-Comdr.—B. S. Collings to *Marshal Soult* and to *Canterbury*.

Surg. Lts.—H. Gow to *Marshal Soult*; P. J. Maguire to *Tiger*; and J. L. Lean to *Victory*, for R.N. Hospital, Haslar.

ROYAL NAVAL VOLUNTEER RESERVE.

Prob. Surg. Lt. (D) L. A. T. McLean is confirmed in his rank.

Prob. Surg. Sub-Lt. D. R. W. Burbury to be Surg. Sub-Lt.

ROYAL ARMY MEDICAL CORPS.

Capts. to be Majs.: D. McKelvey, C. H. K. Smith, C. Wilson, H. N. Stafford (Prov.), and J. B. Fotheringham.

TERRITORIAL ARMY.

General List.—Maj. H. W. Symons to be Lt.-Col. and to comd. the 49th (2nd Northern) Casualty Clearing Station, vice Lt.-Col. (Bt. Col.) F. Darlow vacated.

Capt. F. W. Martin resigns his commn. and retains his rank.

Capt. J. A. L. Loudon resigns his commn. and is granted the rank of Lt.

Lt.-Col. C. Helm, Res. of Off., to be Capt.

Capt. T. L. Clark, late R.A.M.C., to be Capt.

Capt. D. Crellin, R.A.M.C., to be Div. Adjt., 46th (N. Midland) Div., vice Maj. E. A. P. Brock, R.A.M.C., vacated.

Capt. M. C. Paterson, R.A.M.C., to be Div. Adjt., 50th (Northumbrian) Div., vice Maj. J. M. Mackenzie vacated.

General Hospitals.—Lts. R. Riley and G. B. W. Walker resign their commns.

RESERVE OF OFFICERS.

Capt. (Bt. Maj.) J. B. Orr, from the Active List, to be Capt. (Bt. Maj.).

SUPPLEMENTARY RESERVE OF OFFICERS.

Capt. A. D. Gorman, late R.A.M.C. Spec. Res., to be Lt., and relinquishes the rank of Capt.

ROYAL AIR FORCE.

Temp. Capt. E. A. Wheeler, General List (Army), Dental Surgeon, is granted a temporary commission as a Flight Lt. on attachment to the R.A.F.

Flight Lt. J. J. Boyle (Capt., Army Dental Corps), relinquishes his temporary commission on return to Army duty.

INDIAN MEDICAL SERVICE.

Lt. W. Lawrie to be Capt. (prov.).

Sat Chit Anand, J. T. Fernandez, Lachhman Das Sarronwala, and Henry Brij Nath Swift to be Temp. Lts.

The King has approved the retirement of Maj.-Gen. Sir R. Charles Macwatt, C.I.E., K.H.S.

HONORARY SURGEON TO THE KING.

His Majesty has approved of the appointment of Maj.-Gen. J. S. Gallie, C.M.G., D.S.O., late Royal Army Medical Corps, to be honorary surgeon to the King, in succession to Maj.-Gen. D. J. Collins, C.B., C.M.G., late Royal Army Medical Corps, who has retired.

Medical Diary.

Information to be included in this column should reach us in proper form on Tuesday, and cannot appear if it reaches us later than the first post on Wednesday morning.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

MONDAY, Nov. 22nd.—8 P.M., ODONTOLOGY. Dr. E. W. Fish will read Further Notes on the Lymph Supply of Enamel and Dentine to open the discussion on his Original paper read before the Section on April 26th.

TUESDAY.—5 P.M., MEDICINE. Discussion on The Diagnosis and Treatment of Colitis. Dr. A. F. Hurst and other speakers.

WEDNESDAY.—5 P.M., COMPARATIVE MEDICINE. Dr. H. H. Scott: Tuberculosis in Captive Wild Animals as Compared and Contrasted with the Disease in Man.

THURSDAY.—5.30 P.M., BALNEOLOGY AND CLIMATOLOGY. Dr. R. Ackerley: The Spa Doctor's Contribution to the Improvement of National Health. The annual dinner of the Section will be held at the Café Royal at 7.30 the same evening. 8.30 P.M., UROLOGY. Clinical Pathological Meeting. Specimens will be on view from the afternoon of Wednesday, Nov. 24th.

FRIDAY.—5 P.M., STUDY OF DISEASE IN CHILDREN. (Cases at 4.30 P.M.) Cases: Dr. Rolleston: Case of Striæ Patellares following Typhoid Fever. Dr. Cautley: (1) Hemiparesis of Sudden Onset; (2) Intra-Pulmonary Cyst? Mr. Twistington Higgins: Case of Winged Scapula. 8 P.M., EPIDEMIOLOGY AND STATE MEDICINE. Paper: Dr. G. F. Buchan (M.O.H. Willesden): The Hospital in Relation to the Public Health.

MEDICAL SOCIETY OF LONDON, 11, Chandos-street, Cavendish-square, W.

MONDAY, Nov. 22nd.—8.30 P.M., Discussion on Recent Advances in the Treatment and Diagnosis of Bronchiectasis, to be introduced by Dr. Clive Riviere, followed by Mr. J. E. H. Roberts.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, W.

MONDAY, Nov. 22nd, to SATURDAY, Nov. 27th.—FELLOWSHIP OF MEDICINE. Special lecture at the Medical Society of London, 11, Chandos-street, Cavendish-square, W. Thurs., 5 P.M., Mr. Harold Chapple: The Emergencies of Pregnancy and Parturition. Free to members of the medical profession.—ST. MARK'S HOSPITAL, City-road. Tues., 11 A.M., Mr. B. Leggett: Radiological Investigation of the Colon and Rectum. Free to members of the medical profession.—ROYAL LONDON OPHTHALMIC HOSPITAL, City-road. Wed., 12 noon, Clinical Demonstration. Free to members of the medical profession.—ROYAL WATERLOO HOSPITAL, Waterloo-road, S.E. Special course in Medicine, Surgery, and Gynæcology.—ST. JOHN'S HOSPITAL, Leicester-square, W.C. Special course in Dermatology. Practical demonstrations in pathology if desired.—ST. MARK'S HOSPITAL, City-road. Week's comprehensive course.—WEST END HOSPITAL FOR NERVOUS DISEASES, 73, Welbeck-street. Late afternoon course (5 P.M.), demonstrations upon selected cases. Further information from the Secretary.

UNIVERSITY COLLEGE, Gower-street, W.C.

WEDNESDAY, Nov. 17th.—5 P.M., Dr. C. H. Best: Insulin. (Third of four advanced lectures in Physiology.)

POST-GRADUATE HOSTEL, Imperial Hotel, Russell-square, W.C.

MONDAY, Nov. 22nd.—9 P.M., H. J. Patterson: Gastro-enterostomy.

THURSDAY.—9 P.M., Symposium: Cerebral Localisation in the Clinical Subject. The following will take part: Dr. M. Gordon Holmes (Chairman), Dr. W. J. Adie, Mr. Donald Armour, Mr. A. P. Bertwistle, Dr. Carmichael, Dr. Macdonald Critchley, Mr. L. Bathe Rawling, Dr. F. M. R. Walshe.

HOSPITAL FOR SICK CHILDREN, Great Ormond-street.

THURSDAY, Nov. 25th.—4 P.M., Mr. Fairbank: Coxa Vara.

CENTRAL LONDON THROAT, NOSE AND EAR HOSPITAL, Gray's Inn-road, W.C.

FRIDAY, Nov. 26th.—4 P.M., Mr. Gill Carey: Diagnosis of Sinus Disease.

NATIONAL HOSPITAL, Queen-square, Bloomsbury, W.C.

MONDAY, Nov. 22nd.—2 P.M., Dr. Hinds Howell: Out-patient Clinic. 3.30 P.M., Mr. Elmquist: Demonstration of Re-educative Methods in Exercise Room.

TUESDAY.—2 P.M., Dr. Walshe: Out-patient Clinic. 3.30 P.M., Mr. Armour: Cranio-cerebral Topography.

THURSDAY.—2 P.M., Dr. Kinnier Wilson: Out-patient Clinic. 3.30 P.M., Dr. Gordon Holmes: Cerebral Disturbances of Vision.

FRIDAY.—2 P.M., Dr. Adie: Out-patient Clinic. 3.30 P.M., Mr. Elmquist: Demonstration of Re-educative Methods in Exercise Room.

WEST LONDON POST-GRADUATE COLLEGE, West London Hospital, Hammersmith, W.

MONDAY, Nov. 22nd.—10 A.M., Mr. MacDonald: Genito-Urinary Operations. 12 noon, Mr. Simmonds: Fractures and Applied Anatomy. 2 P.M., Mr. Donald Armour: Operations.

TUESDAY.—10 A.M., Medical Registrar: Clinical Methods. 12 noon, Dr. Burrell: Chest Cases. 2 P.M., Mr. Sinclair: Surgical Out-patients.

WEDNESDAY.—12.15 P.M., Dr. Burnford: Medical Pathology. 2 P.M., Mr. Tyrrell Gray: Operations. 2 P.M., Dr. Owen: Medical Out-patients.

THURSDAY.—10 A.M., Dr. Grainger Stewart: Neurological Department. 2 P.M., Mr. Bishop Harman: Eye Department. 3 P.M., Sir Henry Simson: Gynæcological Wards.

FRIDAY.—10.30 A.M., Dr. Dowling: Skin Dept. 11 A.M., Dr. Pritchard: Modern Methods in Medicine. 2 P.M., Mr. Vlasto: Throat, Nose and Ear Dept.

SATURDAY.—9.30 A.M., Dr. Burnford: Bacterial Therapy. 10 A.M., Mr. Banks-Davies: Operations on Throat, Nose, and Ear.

Daily, 10 A.M. to 5 P.M., Operations, Medical, Surgical, and Special Out-patient Departments, Saturdays, 10 A.M. to 1 P.M.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.
MONDAY, Nov. 22nd.—10 A.M. Surgical Clinic. 2 P.M., Medical Cases in the Wards. 2.30 P.M. to 5 P.M., Medical, Surgical, and Gynæcological Clinics. Operations.
TUESDAY.—2.30 P.M. to 5 P.M., Medical, Surgical, Throat, Nose, and Ear Clinics. Operations.
WEDNESDAY.—2.30 P.M. to 5 P.M., Medical Skin and Eye Clinics. Operations.
THURSDAY.—11.30 A.M., Dental Clinic. 2.30 P.M. to 5 P.M., Medical, Surgical, and Ear, Nose, and Throat Clinics. Operations.
FRIDAY.—10.30 A.M., Throat, Nose, and Ear Clinics. 2.30 P.M. to 5 P.M., Surgical, Medical, and Children's Diseases Clinics. Operations.
On Wednesday, Nov. 24th, and Friday, Nov. 26th, at 2.30 P.M., there will be special demonstrations of Eye and Medical Cases by Mr. N. B. B. Fleming and Dr. F. G. Crookshank respectively.

LONDON SCHOOL OF DERMATOLOGY, St. John's Hospital, 49, Leicester-square, W.C.
TUESDAY, Nov. 23rd.—5 P.M., Dr. A. Whitfield: Diseases Due to Fungi (2).
THURSDAY.—5 P.M., Dr. J. H. Sequeira: Tuberculosis Cutis (1).

ST. JOHN'S HOSPITAL DERMATOLOGICAL SOCIETY (Incorporating the London Dermatological Society), 49, Leicester-square, W.C.
WEDNESDAY, Nov. 24th.—4.15 P.M., Clinical Cases will be shown.

ST. MARGARET'S HOSPITAL FOR WOMEN, Acomb-street, Whitworth Park, Manchester.
WEDNESDAY, Nov. 24th.—4 P.M., Mr. A. C. Magian: Electrotherapeutics and X Rays in Gynæcology.

UNIVERSITY OF SHEFFIELD POST-GRADUATE CLINICS.
FRIDAY, Nov. 26th.—3.30 P.M., at the Royal Infirmary: Mr. Mouat: Septic Infections of the Hand.

ANCOATS HOSPITAL POST-GRADUATE COURSE.
THURSDAY, Nov. 25th.—4.15 P.M., Mr. F. Holt Diggle: Tonsillectomy.

JAMES MACKENZIE INSTITUTE FOR CLINICAL RESEARCH, St. Andrews.
TUESDAY, Nov. 23rd.—4 P.M., Prof. Adam Patrick: Diabetic Coma. Discussion to be opened by Dr. A. Hynd.

MANCHESTER ROYAL INFIRMARY POST-GRADUATE COURSE.
TUESDAY, Nov. 23rd.—4.15 P.M., Dr. A. E. Barclay: Radiology in Relation to Medicine, Particularly to Compensation Work.
FRIDAY.—4.15 P.M., Dr. G. R. Murray: Adaptability in Disease.

ROYAL INSTITUTE OF PUBLIC HEALTH, 37, Russell-square, W.C.
WEDNESDAY, Nov. 24th.—4 P.M., Dr. C. W. Saleeby: From Heliotherapy to Heliohygiene.

CHADWICK PUBLIC LECTURES.
MONDAY, Nov. 22nd.—7.30 P.M. (in the Lecture Hall of the University of Sheffield). Mr. H. E. Stilgoe: Water-Supply in its Relation to Public Health.

Appointments.

FAIRER, J. A., M.D. Manch., D.P.H., has been appointed County Medical Officer of Health for Leicestershire.
JAGO, J. W., M.B., Ch.B. Sheff., Certifying Surgeon under the Factory and Workshop Acts for the Eyam District of the County of Derby.
SAVAGE, J. J., M.B., B.Ch. Oxf., F.R.C.S. Eng., Resident Medical Officer of the Freemasons Hospital and Nursing Home.
SMITH, A. GORDON, M.B., Ch.B. Edin., F.R.C.S. Eng., Professor of Anatomy in the Medical College, Ceylon.
St. Paul's Hospital, Endell-street, W.C.: MUTCH, N., M.A., M.D. Camb., F.R.C.P. Lond., Honorary Physician; O'DONOVAN, W. J., M.D. Lond., M.R.C.P. Lond. Honorary Physician in Charge of Skin Department; COOK, F., M.B. Lond., F.R.C.S. Eng., Honorary Gynæcologist.
University of Manchester: SUSMAN, W., M.D. Ontario, Lecturer in Morbid Anatomy and Histology; POLSON, C. J., M.B., Ch.B. Birm., Assistant Lecturer in Chemical Pathology; DOWNIE, A. W., M.B., Ch.B. Aberd., Assistant Lecturer in Bacteriology.

Vacancies.

For further information refer to the advertisements columns.

Brighton, Royal Sussex County Hospital.—Cas H.S. £120.
Brighton, Sussex Maternity and Women's Hospital.—Second Res. H.S. £100.
Bristol General Hospital.—Hon. Clin. Assts.
Cambridge, Addenbrooke's Hospital.—H.S. At rate of £130.
Cancer Hospital, Fulham-road, S.W.—Pathologist. £1000. Also H.S. At rate of £100.
Cancer Hospital, Fulham-road, S.W.—Jun. Radiologist. £500.
Canterbury, Kent and Canterbury Hospital.—Two Res. M.O.'s. At rate of £125.
Carlisle, Cumberland Infirmary.—Hon. Surg.
Central London, Throat, Nose and Ear Hospital, Gray's Inn-road, W.C.—Out-patient Registrar. £30. Also Asst. Out-patient Registrars.
Charing Cross Hospital, W.C.—Res. M.O. £400. Res. Anæsthetist. At rate of £100. Also Asst. P.
Chelsea Hospital for Women, Arthur-street, S.W.—Jun. H.S. At rate of £100.
East African Medical Service.—Two Asst. Bacteriologists. £600.
Eastern Dispensary, Leman-street, E.—Gynæcologist.
Evelina Hospital for Children, Southwark, S.E.—H.S. £120.
Great Yarmouth General Hospital.—H.S. £150.
Hammersmith School, Treatment Centre.—Surg. for Ear, Nose and Throat Dept.
Hampstead General and North-West London Hospital, Haverstock-hill, N.W.—H.S. Also Cas. Surg. O. to Out-patient Dept. Each at rate of £100.
Hospital for Sick Children, Great Ormond-street, W.C.—H.P. and H.S. Each at rate of £50.
Hull Royal Infirmary.—Asst. H.P. At rate of £130.
Ipswich, Heathfield Infirmary, &c.—Asst. Res. M.O. £250.
Italian Hospital, Queen-square, W.C.—H.S. At rate of £80.
Kirkcaldy Hospital.—Res. M.O. At rate of £125.
Lincoln County Hospital.—Jun. H.S. £150.
London Temperance Hospital, Hampstead-road, N.W.—Hon. P.
Lucknow University.—Prof. of Anatomy. Rs.1450 per mensem.
Manchester Northern Hospital for Women and Children.—Sen H.S. and Jun. H.S. £130 and £100 respectively.
Manchester Royal Infirmary.—Res. M.O. £200.
Margate, Royal Sea-Bathing Hospital for Surgical Tuberculosis.—Two H.S.'s. At rate of £200.
Metropolitan Ear, Nose and Throat Hospital, Fitzroy-square. Anæsthetist.
Miller General Hospital for South-East London, Greenwich-road S.E.—Asst. P. and two Asst. S.'s.
National Hospital, Queen-square, W.C.—Res. M.O. £200.
Nordrach-upon-Mendip Sanatorium, Blagdon, near Bristol.—Asst. M.O.
Norwich, Norfolk and Norwich Hospital.—Cas. O. and H.S. £120.
Oxford, Wingfield Orthopædic Hospital.—Res. Surg. O. and H.S. At rate of £200 and £150 respectively.
Prince of Wales's General Hospital, N.—Hon. Clin. Assts.
Queen Mary's Hospital for the East-End, Stratford, E.—Res. M.O H.S.'s., H.P.'s., &c.
Royal College of Physicians, Pall Mall East.—Milroy Lecturer for 1928.
Royal Free Hospital, Gray's Inn-road, W.C.—Surg. Reg. £200 Med. and Gynæcological Regs. Each £100. Also H.S.'s. H.P., &c. £100 each.
St. John's Hospital, Lewisham, S.E.—Cas. O. At rate of £100.
St. Marylebone General Dispensary, 30, Marylebone-lane, W.—Hon. Asst. in Ultra-Violet Radiation Dept.
St. Thomas's Hospital.—Surgical Registrar.
Salford Royal Hospital.—Two Hon. Asst. S.'s.
Shanghai Municipal Council, Public Health Dept.—Asst. Pathologist. Tls.600 per mensem.
South Uist Parish and Northern Division.—M.O. and Pub. Vaccinator. £620.
Southwark Hospital, East Dulwich-grove, S.E.—Radiologist. 150 guineas.
Stockport Infirmary.—Three Visiting Anæsthetists.
University College Hospital, Gower-street, W.C.—Two Clin. Assts. to X Ray Dept.
Windsor, King Edward VII. Hospital.—Jun. H.S. At rate of £100.

The Chief Inspector of Factories announces the following vacant appointments for Certifying Factory Surgeons: Cannock (Staffs), Woolpit (Suffolk), Littleborough (Lancs), and Clacton-on-Sea (Essex).

Births, Marriages, and Deaths.

MARRIAGES.

ANDREAE—BROWN.—On Oct. 16th, at Mussoorie, India, Eric Burn Andreae, M.R.C.S., L.R.C.P., to Edith Muriel Brown younger daughter of the late Rev. Alexander Brown and of Mrs. Brown, Trevail, Grampound.
DICKINSON—CLARKE.—On Nov. 15th, at St. Mary Abbot's, Kensington, C. R. Dickinson to Gladys Maud Clarke L.R.C.P., M.R.C.S.
MURRAY—LAING.—On Nov. 10th, at Queen-street Congregational Church, Arbroath, John Murray, *M.C.*, M.B., Ch.B Manch., to Agnes Ferguson, elder daughter of David Laing, T.D., M.D., and Mrs. Laing, Arbroath.

DEATHS.

FRY.—On Nov. 9th, Walter Ernest Fry, M.R.C.S., L.R.C.P. D.P.H., of West Kensington-gardens, W.
PALMER.—On Nov. 12th, at Stoke House, Gosport, Hants Charles John Linton Palmer, M.R.C.S., L.R.C.P., aged 54 years.
RANDLE.—On Nov. 14th, suddenly, Horace Andrews Randle M.D., of Pendleton, Lancashire, and Birkbeck-road Acton, W., aged 71.
REYNOLDS.—On Nov. 12th, 1926, at 730, Fulham-road, S.W. Joseph Henry, M.B., C.M. Edin., the dearly beloved husband of Blanche Reynolds, and son of James Reynolds, Esq. of Gloucester, aged 56.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Comments, and Abstracts.

GARAGE ACCIDENTS.

WITH the growth of motoring has grown also the tale of motor accidents, and an inconspicuous but none the less an important and interesting class of these take place in the garage. A few garage accidents are caused by the mishandling of electric current or by starting the engine with the gear in, but the majority are due to poisoning by exhaust gases. Although motoring is thirty years old, and the first warning against the danger of running an engine in a confined space was published twenty years ago, a very small number even of professional drivers are aware of the deadliness of exhaust fumes. The reason for this ignorance is possibly that carbon monoxide, the lethal constituent of these fumes, kills without leaving any obvious trace, and many garage deaths are wrongly ascribed to apoplexy. The presence near the body of gastric contents is likely to mislead the police or local practitioner into suspecting an alcoholic condition, and the symptoms, if observed, support the mistake. In other cases epilepsy and petrol poisoning are wrongly suggested as causes of death. The gases are the product of the imperfect combustion of hydrocarbons, and the worse the combustion the greater will be the output of CO, which with CO_2 constitutes the bulk of the fumes. A dangerous concentration—according to some experiments 1 in 1500—may easily be reached in narrow lanes, corners, and roofed spaces. When an engine is run in a small closed shed it produces a high concentration at once, especially if the carburetter air vent is closed or nearly so. As much as 14 per cent. is reached in a few minutes, but before this occurs the driver, if he has been imprudent enough to shut himself in with the car, is dead. Even coal gas, at its worst, contains no more than 5 to 10 per cent. of CO, and no one would stay in a kitchen with unlighted gas streaming from the oven jets, but he would be safe there compared with the car owner working on a running engine in a small garage. CO is the deadlier for being odourless and colourless. A concentration of 1 in 1000 or 1 in 2000 will saturate the blood in an hour or less to the 60 per cent. or so at which death occurs. Even as minute a trace in the atmosphere as 1 in 5000 will produce headache, malaise, and unsteadiness of the legs in two to three hours. As might be expected, therefore, 3 per cent. will produce symptoms of acute poisoning in a quarter of an hour, and less if the subject is working hard. The safety limit in American mines is held to be 1 in 5000. Besides poisoning the air, a running engine quickly uses up the oxygen. The concentration is heaviest at first just at the end of the exhaust pipe, and the owner moving to and fro stirs the mixture. He notices nothing for a time, but then suddenly, especially if he happens to take a deep breath of an extra strong concentration, he feels a violent headache, a loss of balance, and a deadly weakness at the knees. His efforts to breathe make matters worse, and, sinking to the floor where the fumes are heaviest, he soon succumbs. Many professional drivers are familiar with the beginning of this syndrome, but few treat it with the importance it deserves.

Dr. J. Dettling[1], of the Medico-Legal Institute of Zürich University, has been studying the question from the point of view of public security, and has suggested certain precautions which should, if given the status of law, minimise what is undoubtedly a growing public danger. He proposes that every place where cars are stored should have permanent and ample communication with the outside air, such as large unclosable ventilators. This will excite the wrath of owners by forcing them to empty their radiators every night in winter, but that cannot be helped. Further, the running of an engine in a small garage should, he suggests, be absolutely forbidden, as poisoning can occur even with open doors and windows. It should be obligatory to post an official warning in all garages. Real and lasting prophylaxis, however, can only be undertaken by physician, sanitary official, architect, motorist, and chemist working in coöperation.

SANOCRYSIN IN PULMONARY TUBERCULOSIS.

A PAPER on the immediate results of treating pulmonary tuberculosis with sanocrysin appears in the *Semana Medica* of Oct. 7th. The authors, Dr. E. M. F. Rey, Dr. F. E. Soneo, and Dr. Priam, give the results of treatment in fifty cases which had not been benefited by previous care in a sanatorium. They are not very enthusiastic about the results, which, they say, were "not so favourable as they could have wished." Of the 50 treated, 33 improved, those state without sanocrysin might have remained stationary or got worse; 12 remained the same, 3 died, and 2 were worse. On their face value these figures appear satisfactory, and justify the authors' opinion that sanocrysin, with other gold preparations, should be considered as a weapon in the antituberculous armoury, pending further improvements in their preparation and use. They mention a case of acute miliary tuberculosis in which "unexpected results" followed treatment, but they give no details, and unfortunately do not include a description of it in their list.

PRACTICAL JOKES WITH COMPRESSED AIR.

WITH the ever-increasing use of high-pressure air for drills, riveters and industrial cleaning, more and more men are being brought in to first-aid stations with rupture of the bowel. Considering the amount of compressed air that is used in this country it is rather surprising that clinical accounts of these accidents all seem to appear in foreign publications. The disaster is generally due to the misguided humour of a fellow worker who has thought that it would be an excellent joke to inflate his unsuspecting companion per rectum. The first case, mentioned by Dr. G. W. Stone, of London, is the only one on record in which the nozzle of the hose was believed actually to have been inserted in the anus. Drs. F. B. Block and M. I. Weissman described a typical case, in the Journal of the American Medical Association for May 22nd, in which the patient had a tear an inch long at the junction of the rectum and sigmoid. The column of air had forced itself through several layers of clothing and the two sphincters although the nozzle was held an inch or more away from the body. Dr. A. W. Andrews[1] gave a reasonable explanation by pointing out that air at a pressure of 100 lb. or over forms a solid column several inches long in front of the nozzle, while the floor of the pelvis, owing to its peculiar construction, constitutes a funnel with the anus at its apex. The involuntary contraction of the levator and sphincter narrows and deepens the funnel, assisting the air to enter the bowel. Moreover, it only requires a pressure of 7 to 12½ lb. to rupture the intestinal wall. The most recent review of the subject appears in the same journal[1] for October last, where Dr. George L. Hays records 32 cases culled from medical literature. No doubt there are many observations which are never reported. Dr. Hays also mentions a report by Petrin[2] of a fatal accident which was caused by a workman trying to shut off pressure by kinking the hose and then holding the end between his teeth. He slipped and relaxed his hold, and the air stream ruptured his œsophagus. The condition of rupture of the bowel is not hard to diagnose, as the abdomen is enormously distended and is tympanitic all over, and the history will reveal the connexion with high-pressure air. It ought to be possible to prevent all but a very few of these accidents by the systematic publication of oral and printed warnings, in which attention is called to the fact that the nozzle of the apparatus need not actually be in contact with the body to produce serious injury. The most effective treatment is emergency puncture and early laparotomy. The sigmoid is usually the site of the rupture, for the anus and rectum escape injury because of their outside support.

COLDS AND CHILL.

SOME years ago Mr. Alexander Francis[3] said that in nine cases out of ten a chill is the exciting cause of an infective catarrh, and suggested that what usually lies behind the chill is an unstable vasomotor system. With such instability, he said, a draught or sudden change of temperature produces a localised vaso-constriction, with a compensatory vaso-dilatation elsewhere. If this area of dilatation happens to be in the mucous membrane of the naso-pharynx or bronchial tubes "it provides, as it were, an incubator for the organisms lurking there, which suddenly bursts into activity and a catarrh results." A similar suggestion has now been put forward in France by Dr. Jean Tarneaud,[4] who, while accepting the infective origin of colds, believes that the causal factor in the vast majority of cases is a shock to the vegetative nervous system caused by a sudden change in temperature. This shock, he considers, causes a reflex vasomotor disturbance of the nasal mucous membrane, which disturbance "allows the infective element to come into play." The arguments put forward in support of his contentions are the general liability to colds at times of sudden change in the weather, the special liability of certain persons to them after any exposure to cold, and the fact that a congestion of the nasal mucous membrane is the invariable first sign of an attack. Dr. Tarneaud claims that the only effective prophylactic treatment is that which aims at lessening the sensitiveness of the nervous system to shock and of the nasal mucosa to vascular disturbances—i.e., general hygiene aiming at desensitisation to cold—and

the local use of the galvano-cautery. The only drugs which are useful, he thinks, are those which affect the vegetative nervous system, such as adrenalin, aconite, and belladonna.

These suggestions are interesting, but it has to be remembered that the local vascular dilatation which these observers believe to be so harmful in favouring the growth and penetration of pathogenic germs is the natural response throughout the body to microbic infection. From this it might be assumed to be a defence rather than a source of weakness, and, in fact, we are taught that the increased secretion helps to wash away germs while the increased blood-supply dilutes the toxins and increases the phagocytic defences. And yet it must be admitted that chronic, as opposed to acute, congestion does favour microbic invasion as the beneficial results of removing such congestion by various local operations testify. Probably there are many different types of cold, from the undoubtedly infectious ones which occur in epidemics to the transient rhinorrhœa which afflicts sensitive people after the slightest chilling. It is the first of these on which emphasis is laid, for example, in Prosser White's monograph on Catarrhal Fevers, whilst the second seems to be the type which has chiefly come under the notice of Dr. Tarneaud.

CONTRACEPTION BY SPERMATOXIN.

Dr. S. S. Rosenfeld, adjunct gynæcologist and obstetrician at the Lebanon Hospital, New York, has carried out some interesting experiments on the production of a spermatoxin in human beings immunised with injections of living spermatozoa. The preliminary report appears in the *American Journal of Obstetrics and Gynecology* (vol. xii., No. 3). Three women received repeated injections of human semen, but in no case was a spermatoxic reaction subsequently demonstrable in the serum. Negative results were obtained after the use of both living and dead spermatozoa. It has, of course, been claimed that women who have been injected with semen can avert pregnancy for about 20 months, the temporary sterility being due to the production in their blood of a spermatoxic antibody. If this is correct a new contraceptive method would become available for women in whom pregnancy is contra-indicated. Dr. Rosenfeld's results appear, however, to throw doubt on these statements. At any rate in the light of his experience many injections of semen would appear to be necessary in order to obtain a temporary sterility, so that as a practical contraceptive method immunisation with injections of semen need not be considered very seriously.

AN INSURANCE COMPANY'S NURSING SERVICE.

IN 1924 the Mutual Property Insurance Company, Ltd., of London, instituted a free nursing service for the benefit of its sickness and accident policy-holders. These people, who are mainly of the industrial classes, received attention and advice at the hands of a nursing sister, who visited her patients by car. As more and more patients began to take advantage of the service, it was found impossible for a single visiting nurse to carry on the work. In April, therefore, the service was reorganised, and the policy-holders, instead of receiving visits from the Company's nurse, are now attended by members of 96 district nursing associations with which the Company has become affiliated. The cost of the visits is entirely defrayed by the Company, and the policy-holders naturally receive more prompt attention than was formerly possible.

Since this nursing service was started in 1924, nearly 9000 visits have been made; the fact that 1100 of these were made during September last shows that the scheme is growing in its scope. In connexion with this welfare work, the Mutual Property Insurance Company has distributed over 300,000 folders and leaflets dealing with personal health.

COÖPERATIVE BABY CARE.

THE little book, "To Wives and Mothers," published by the National League for Health, Maternity, and Child Welfare, has long been recognised as a useful guide in the daily task of caring for children and in facing the common difficulties which arise in most homes where there is a young family. The eighth edition has just been published under the new title "To Mothers and Fathers."[1] As the new chapter on a Father's Duty only occupies two and a half pages, it is evidently intended that the father, equally with the mother, should acquaint himself with the earlier chapters; he is indeed specially recommended to study the section on the expectant mother, to make sure that all proper precautions are being taken and preparations made for the safeguarding of his wife and the coming child. His responsibility in giving the baby the best chance, by keeping the rules of the game, is also emphasised, as in the sentence: "Regular feeding will only be possible if you help; if you are out with your wife you must make it your duty to bring her home in time for baby's feed."

The preface expressly states that the booklet is not designed to replace medical and other expert advice available at a welfare centre, but it contains in its 79 pages a remarkable amount of homely counsel on the well-being of the expectant and nursing mother, on many aspects of child-care up to the age of 5, and on home management, as well as sound hints on the nursing of various illnesses, and the avoidance of spreading infection. The table on p. 64, setting out the period of incubation, of quarantine, and the time when the patient may be regarded as free from infection after the commonest infectious diseases, is especially useful. The few misprints scarcely mar a well-balanced and carefully compiled pamphlet.

WEIGHTS AND MEASURES.

To the Editor of THE LANCET.

SIR,—Old table books tell us that apothecaries mix their medicines by apothecaries' weight, but buy and sell their drugs by avoirdupois weight. The apothecaries' *drachm* is 60 grains, and the avoirdupois *dram* 27½ grains; the apothecaries' ounce 480 grains (precisely the weight of 5*s.* 6*d.* in silver); the avoirdupois ounce 437½ grains (practically the weight of 5*s.* in silver). If a scruple is asked for, it is distinctly 20 grains (practically the weight of a 3*d.* bit); but if a drachm or dram (the sound is the same) or an ounce is demanded, what is supplied over the counter, retail or wholesale? If the demand is in writing, and the apothecaries' symbol for drachm or ounce prefixed, I presume that 60 or 480 grains are supplied, and if dr. or oz. is prefixed, 27½ or 437½ grains are supplied. But where ambiguity arises, is it left to the discretion of the server how many grains to supply? I have been told that the British Pharmacopœia of 1864 changed the weights and measures from apothecaries' to imperial, and that the apothecaries' symbols were then applied wrongfully to avoirdupois weights and measures.

I am, Sir, yours faithfully,

London, Nov. 5th, 1926. PERTINAX.

A DOUBTFUL COMPLIMENT.

A PHYSICIAN attached to an important hospital sends us the following letter recently received from a patient:—

DEAR SIR,—Please excuse my writing to you, but could you tell me which hospital I could see you at, or the lowest fee you accept. My poor brother came to see you but it cost him £2 2*s.* I could not possibly pay that as I do not possess it. I am suffering something awful with my head particularly when the menses are on. I am a married woman with three children. My husband is a carpenter. I have already undergone an operation for gall-stones, and I pray to God to be able to see you. If only you could tell me this dizziness is due to my liver it would put a new lease on my life. I don't want to see anyone but yourself. After what you said of my brother, I have faith in your very name. I have a bald patch on the left side of my head and it seems as if my head is always in a vice, and it affects my eyes. Four years ago next month, my brother came to see you on a Monday, and died on Friday 6 o'clock in the same week. Hoping and praying you will see me. Thanking you in anticipation. I remain, yours faithfully,

A. B.

PUBLIC HEALTH IN SEYCHELLES.

Mr. J. L. Devaux, Administrator, reports that the population of the colony on Dec. 31st, 1924, was estimated at 25,847, an increase of 1324 since the census of 1921. There were 178 marriages during the year, or 70 more than in 1923. The births number 723, corresponding to a rate of 29·97 per 1000. The deaths totalled 378, or 14·62 per 1000. The estimated number of square miles comprised in the Seychelles islands and dependencies is 156¼. Mahé is the largest and most populous island and is distant from Mauritius 934, from Madagascar 600, and from Zanzibar 970 miles. It is mountainous, fertile, and has an area of about 55 square miles. The climate is quite healthy, and, owing to the absence of the anopheline mosquito, malaria does not occur. The maximum shade temperature rarely exceeds 86°, but even at night the temperature seldom falls below 74°. The rainfall averages about 90 inches, although in some years it has reached 115 inches.

Corrigendum.—In the discussion on the Management of Contracted Pelvis at the Harveian Society (THE LANCET, Nov. 13th, p. 1010), Dr. G. de Bec Turtle should have been reported as saying that Walcher's position was of some value in increasing the size of the *inlet* in cases of flat pelvis, and that in the high forceps operation it was best to remove the instruments after bringing the head down *into the pelvic cavity.*

THE

Lloyd Roberts Memorial Lecture

ON

RACIAL DEGENERATION.

Delivered before the Royal College of Physicians of London on Nov. 19th, 1926,

BY THE VERY REV. W. R. INGE, C.V.O., D.D.,
DEAN OF ST. PAUL'S.

THIS is the second time in one year that I have been honoured by being appointed to give a lecture to the medical profession and their friends. I have accepted, because those who invited me must know my limitations, and will not expect from me what I am obviously incompetent to give. In my Fison lecture at Guy's, a few months ago, I spoke of the philosophy of science, of the relation of philosophy, particularly the philosophy of religion, to science. Though my treatment of the subject was necessarily cursory, I could not give a second address on the same topic, especially as my lecture has been published; and so I have decided to take as my subject to-day one aspect of a branch of science in which I have been keenly interested for many years, ever since, as a near neighbour of Sir Francis Galton in Rutland Gate, I learned from that fine old man to feel some of his own enthusiasm about the possible improvement of the human stock. For me it has, of course, been a hobby rather than a rigorous study, and I should not dream of supposing that any utterances of mine on these abstruse and difficult studies can have any value as contributions to knowledge. They will deal rather with the borderland between strict science and practical social hygiene. Politics ought to be a branch of social hygiene, though at present social hygiene is hardly even a branch of politics. *Salus populi suprema lex*, as the proverb says; and we may give *salus* its commonest meaning of bodily and mental health. *Sanitas sanitatum, omnia sanitas*, is Disraeli's parody of Ecclesiastes. The subject of racial decadence is one of supreme public interest; and though I wish I were better equipped with technical knowledge, I hope I may be able to state the problem in such a way as to interest some of you.

NEGATIVE EUGENICS.

I have taken the negative side of eugenics rather than the positive, racial degeneration rather than race improvement, not because I have any natural tendency to dwell on the dark side of the changes which are always going on in the human race, but because at present negative eugenics is far more important than positive. We have to consider whether we can counteract the dysgenic effects of a highly artificial civilisation. Natural selection, in a humane and highly civilised country like our own, has almost ceased to operate; if we do not provide some rational substitute for it, Nature will punish us for interfering with her methods of social hygiene without providing anything to take their place. But I hope to give some striking examples of the inheritance of good as well as of bad characteristics.

"To understand what has happened, and even what will happen," said Buffon, "it is only necessary to examine what is happening." But when *ce qui arrive* is what we want to know, that which has happened is our best guide. All science is based on the belief that in natural laws "there is neither variableness nor shadow of turning." This does not exclude what Bergson calls creative evolution, Lloyd Morgan "emergent evolution," and chemists creative synthesis, though in this process there is an unexplained mystery. Biological progress means increasing complexity of structure and function, increasing specialisation and coöperation of parts; and what we call human progress is no more than this. Specialisation always means limitation in some directions. We cannot have both wings and arms (until we become angels); if our limbs are good for running we cannot swim like a fish. Highly differentiated organisms are fit only for certain conditions; when these are changed the organism must perish or return to a less differentiated type. It is only the least differentiated organisms, like the germ-cells, which are potentially immortal.

So there are different paths which evolution may take. In our species we may say that there have been three stages—greater complexity of bodily structure, greater intelligence, and greater social organisation; and it is broadly true that when a new stage begins, the earlier stage becomes less active. If we judge from other living organisms on the earth, stability seems to be the rule, change the exception; though De Vries thinks that periods of mutation and of stability alternate with each other. It is probable that the four ice-ages, divided by long inter-glacial periods, have had a great deal to do with the evolution of humanity. Perhaps Nature has expended nearly all her ingenuity; there have been no new classes since the appearance of mammals and birds in very early times.

Even social evolution seems to have come to an end with the bees and ants. State-socialism can no further go than in these suffragette utopias, governed and run by maiden aunts. These societies are an awful warning; perfect coöperation has sacrificed the individual completely. Fortunately, there are physiological limits to specialisation; men consisting almost entirely of swelled heads, like H. G. Wells's "Grand Lunar," could not live.

Man has been a distinct species for probably more than a million years, but anything like civilisation is a matter of the last ten thousand years or so. This is a very short time for him to adapt himself to revolutionary changes in his habits; we need not wonder that what Metchnikoff calls maladaptations or disharmonies, bodily as well as mental, exist to plague us in our health and conduct. I suppose that pathology is mainly concerned with such disharmonies; it is instructive to observe how very small a part disease plays in the lives of wild animals, which are completely adjusted to their environment.

It is sometimes said that evolution is rapid to start with, when some climatic or other change sets it going, and that it then slows down till it stops. But it seems doubtful whether physical changes are not now going on in our bodily structure as rapidly as ever; only unfortunately they seem to be mainly degenerative. H. F. Osborn enumerates the decreasing size of the little toe, increase in the size of the great toe; decrease in the size and strength of the teeth, and probably a gradual lowering of the perfection of the sense-organs. Dentists, I believe, agree that our jaws are becoming too small for our teeth; the sharp and narrow nose of the northern European may be a new feature, with some value as a protection against respiratory diseases; baldness in middle life is perhaps increasing; and something seems to be happening to that now useless organ the appendix. I believe additions might be made to this list. As regards the organs of sense, I cannot help thinking that our eyesight has deteriorated rapidly. Very few middle-aged men can read a closely written or printed mediæval book without glasses; though the ancient Greeks, a singularly long-lived race, went on reading and writing till extreme old age without mechanical aid.

Any physical changes other than degenerative are inhibited by the use of tools and other inventions. Digestion as well as mastication is made too easy; having clothes and weapons we need neither fur nor claws. And, as I shall show, nearly all the aptitudes which distinguish the handyman from the simpleton are now becoming superfluous. We may some day have a generation who can neither walk nor write; they will rely on the cycle or car for the first, and on the typewriter for the second. "You press the button; we do the rest." Nature will say, "Very

well, I will leave you just enough intelligence to press the button."

HAS HUMAN INTELLIGENCE ADVANCED?

It seems very doubtful whether human intelligence has advanced in the last five thousand years. Look at the Egyptians 3000 years before Christ. "Already," says Austin Freeman, "he is living in large and well-ordered communities with all the machinery of a complex civilisation. He has an established government, a system of jurisprudence, a complex religion, and a wealth of myths and traditions. Though unacquainted with iron, he is an expert metallurgist as to the less refractory metals, with the aid of which he works—and works magnificently—granite, porphyry, syenite, and other of the hardest stones. Not only can he smelt metal, he can work it in every way; draw it into wire, beat it into sheets, cast it, emboss, chase, engrave, and even inlay and enamel it. He has invented the lathe and the potter's wheel, and can make, glaze, and enamel beautiful earthenware. He is an expert woodworker, joiner, and carver. He is an admirable sculptor, draughtsman, and painter. He has developed a great architectural style, and his stone buildings are not only the greatest in size ever erected, but are of unsurpassed excellence of workmanship. He is a builder of sea-going ships of considerable burthen and is a capable coastwise navigator. He has invented the loom, and produces textiles of fine quality. He has a rich language, and has devised a system of written characters, the handsomest ever produced, with a convenient and practical cursive script. He makes excellent paper, and has an extensive, dignified, and beautiful literature. He has numerous musical instruments, including the harp, lute, viol, drum, sistrum, cithern, dulcimer, flute, recorder, trumpet. He has established something approaching a metal currency; has a number of weapons—sword, spear, bow and arrow, sling, boomerang; and has invented most of the hand-tools now in use. He has domesticated the ox, sheep, goat, horse, camel, dog, cat, pig, and various birds, and is an expert agriculturist. He makes furniture of unsurpassed excellence of design and workmanship, and can cut and polish precious stones and set them in beautiful jewellery—in short, he is already acquainted with the essentials of all the arts and crafts, and in many of them he is to this day unexcelled if not unequalled."

I will not go so far as Sir Francis Galton in estimating the comparative intelligence of the ancient Athenian and the modern European; but there can be little doubt that the Greek was our superior. All the great religions, and I think all the great philosophies too, were born in the thousand or twelve hundred years before the death of Mohammed.

Civilisation is mainly the result of accumulated knowledge and experience. Each generation stands on the shoulders of the last, and has the chance of climbing higher from that point. Most of our acquisitions are in the custody of a very few persons. Some of them are trade secrets; others can only be mastered by many years of application. This explains how civilisations occasionally die; it is also an argument for a widely diffused education. A great convulsion, like the breach of the dykes which protected the Græco-Roman world from the barbarians of the north and east, may break the tradition, and cause the total loss of the higher arts and sciences. It is well known that at the Renaissance it was necessary to go back to the fragments which had survived from classical antiquity. In medicine, for example, Celsus and Galen were far in advance of the superstitious and ignorant practice of the Dark Ages. It is unlikely, but not inconceivable, that such a disaster may occur again. In Russia the nation has been almost literally decapitated. When that nation recovers a civilised government, it will have to go to Germany and other countries for the arts and sciences which have been almost extinguished at home. A world-wide revolution of the same kind, such as might follow another great war, would be the end of our civilisation, and the beginning of a new Dark Age which might last for centuries. It might then be found that the present population of the world is less inventive and alert in intelligence than, for example, the Europeans of the Renaissance.

Analogy suggests that where the weight of sustaining civilisation is thrown upon tradition, other faculties, by which man slowly raised himself from savagery, are likely to become partially atrophied. Whether such atrophy can be inherited is, of course, a vexed question among biologists into which I, as an outsider, shall be wise not to enter. The problem is mainly about the manner of the changes conditioned by environment, for there is no doubt that a whale has lost its hind legs by living in the water. (Milton gives the whale gills and a trunk, but he was a poet.) But it cannot be disputed that those qualities which were once essential to progress have no longer the same survival value under civilisations of the modern type. An American eugenist, Holmes of California, sums up the differences between barbarism and civilisation as follows. Among primitive races, natural selection operates actively. Nomads are obliged to leave diseased and feeble members of the tribe behind on their long marches. Superstitious fear causes deformed children to be destroyed. Sexual selection frequently works for race improvement. The African chief, who monopolises half the women of the tribe and is the father of his people in the most literal sense, is usually a man of gigantic stature and strength, and of great vigour of character. Among the Chippewa Indians any one may challenge another to wrestle, and if he wins may carry off his wife as a prize. Savage war tends to an increase of the best stock, since the better fighter kills the worse. This I think is somewhat doubtful. "He who fights and runs away may live to fight another day." On the other hand, among civilised races, natural selection is reduced in some cases, and probably increased in others. In the upper and middle classes marriage is not universal, and though many of the best men and women unfortunately die childless, there is a certain selection against men who cannot make good as salary-earners, and against women who are not likely to make satisfactory mothers. But meanwhile, the State, and private charity, keep alive multitudes who by their misfortune or fault are life-long parasites on the community, and who in many cases are suffering from heritable defects. This dysgenic selection affects a much larger number than the slightly eugenic selection among the well-to-do. Civilised war, says Holmes, eliminates the best. *Immer der Krieg verschlingt die Besten.* This is true, in so far as the unfit are not called to the colours. Such evidence as is available goes to show that considerable injury has been done to the European racial stocks by the Great War. Lastly, in place of the greater fecundity of the barbarian chiefs, the socially successful in civilised countries do not keep up their numbers. Against this it may be said that Plutus is blind, and does not always enrich the best, and that the children and grandchildren of the nouveau riche are not always better specimens of humanity than their poorer neighbours. But on the whole there is no doubt at all that industrial civilisation under a democracy skims off the cream in each generation and then throws much of it away.

The bees and ants have proceeded by extreme differentiation of function. The group has superseded the individual. Is this a desirable ideal for humanity? In some societies a highly cultivated minority has flourished and produced achievements which are the wonder of posterity, but the remainder of the population has remained quite uncivilised and uncared for. There have been biologists who accept this type of state as the best. Herbert Spencer thought that the "beneficent working of the survival of the fittest" must condemn the unsuccessful to "abject misery" and death. "An opposite régime would be fatal to the species." Haeckel says: "The theory of selection teaches us in human life exactly as in animal and plant life, that at each space and

time only a small privileged minority can continue to exist and flourish; the great mass must starve and more or less prematurely perish in misery. We may mourn this tragic fact, but we cannot deny or alter it. Many are called but few are chosen. This selection, this picking out of the chosen, is necessarily combined with the languishing and perishing of the remaining majority." Benjamin Kidd thinks that cut-throat competition "results from deep-seated physiological causes, the operation of which we must always remain powerless to escape." He adds that it is the lofty function of religion to furnish non-rational sanctions for conduct which make for social as opposed to individual welfare.

These sentiments are not likely to commend either biology or religion to those who used to be called the suffering and toiling masses. They represent a path which a nation might take, but, as I believe, to its own undoing. There are several fatal objections to it. Unlimited competition exhausts the competitors, physically and mentally, and in practice, whether voluntarily or involuntarily, it sterilises them. So severe is competition in America that 1,750,000 policy-holders of an insurance company (industrial department) give an average life of 46 years to males and 52 to females. Further, they will either destroy each other or cease to compete. In all the higher human activities competition is not the chief motive force, and in a nation organised solely for big business these higher activities languish. They are squeezed out, as we see in some sections of American society. The millionaire is not the supreme product of human progress. Again, as the result of our industrial régime, there has come about a correlation between failure and fecundity which is an odd comment on Herbert Spencer's beneficent law of the survival of the fittest. Lastly, the most important unit in group competition is the nation, and a nation organised on Haeckel's lines would go to pieces under the first severe strain, as Russia did in the Great War. Or if a privileged military caste made conquests, Nature's law is that the ruling race rules itself out. In Western Europe there are no more wolves; but the sheep hold their own. In short, I do not think that those who wish to keep the masses in a servile state (if there are any such left) can appeal successfully to biology in support of their views. A society with well-marked castes may be very successful, partly because, while encouraging good traditions of skill and requiring a considerable amount of specialisation, it mitigates competition; but not if it includes an ignorant and wretched proletariat. No scheme of social hygiene can be satisfactory that does not include the whole population. The plan of developing to the utmost a small selected class has been tried several times, but it is not proved that equally good results might not have been obtained by other methods involving less injustice.

Social Science and Environment.

We have now to consider whether civilisation is working towards a degeneration of the national stock. We may ask first whether neglect of the known laws of heredity is producing this effect, and, secondly, whether our social arrangements are encouraging the tendency to parasitism, which is always ready to show itself where circumstances are favourable to it. We shall have to consider not only the parasitism of persons or classes on the community, but the new danger that human beings may become parasitic on the machines which they have made for their own use. This last is a source of racial decay which has only lately attracted attention. It is obviously a problem which belongs to the human race alone, since man is the only tool-maker.

It will be generally admitted that our social science has been too exclusively environmental. It is not necessary to minimise what can be done by external means, such as education, sanitation, and increased opportunities for leading a healthy life. Sometimes diseases which were supposed to be hereditary can be eliminated by scientific treatment, as the Swiss valleys have been almost freed from goitre, which was already prevalent there in the time of Juvenal, since that disease has been proved to be due to the absence of iodine; and the supposed congenital inferiority of the inhabitants of subtropical regions in America has been proved to be due to the parasite called the hookworm. It used to be supposed that Europeans were constitutionally unable to keep their health in a tropical climate. But it now seems that in the absence of tropical diseases, such as malaria and yellow fever, which are being brought under control by war against the parasites which cause them, even northern Europeans can live healthily in climates as hot as North Queensland. Still, when all has been said in favour of concentrating attention on the environment, the best authorities are unanimous that Nature is far more important than nurture. Prof. Punnett, for example, says that "permanent progress is a question of breeding rather than of pedagogics; a matter of gametes not of training. As our knowledge of heredity clears and the mists of superstition are dispelled, there grows upon us with an ever-increasing and relentless force the conviction that the creature is not made but born." It is surely significant that these judgments, which go beyond what the observation of life suggests to those who are not specialists in genetics, are maintained so strongly by those who have given their lives to this particular study. There is not much difference, I think, here between the Mendelians and the biometricians, who sometimes show a certain acerbity in criticising each other. Prof. Karl Pearson, the most prominent authority on the statistical study of genetics, comes to the conclusion that if we compare the relative importance of Nature and nurture in determining bodily and mental character, it is found that Nature is at least five times, and perhaps even ten times, more decisive than nurture.

It is true that the transmission of characters is now seen to be far more complex than was once supposed. It is usual now to speak of unit-factors, not of unit-characters. A character, such as marked ability in any direction, is probably due to the combination of several unit-factors, the absence of one of which may spoil the result. No one would claim that much is yet known for certain about the action of "genes" and the laws of their combined action. I could not think of offering any opinion on so abstruse a subject. But we may still learn much by collecting family histories, and observing what qualities tend to reappear in the second and succeeding generations, without even attempting to theorise on the causes of their transmission.

Pedigrees of able families are abundant, ever since Galton inaugurated this method of approach. I think, if I may venture on an opinion, that Galton hardly allowed sufficiently for the good start which the son of an able man has, the stimulating influence of the home circle in which he is brought up, the ambition of following in his father's footsteps, the opportunities of a good education which his father's success affords him, and in some professions, such as politics, the openings which the son of a Cabinet Minister may expect for entering public life, at an age when the member of a politically unknown family is still struggling on the lower rungs of the ladder. We shall also find, if we read the literature of the subject, that a small number of striking pedigrees, such as those of the Bachs, a family of able musicians, and of the Darwins in our own country, are repeated in almost every volume. We need a much larger number of pedigrees, including not only the five-talent but the two-talent men. There are, however, some characters, such as stature and longevity, in which adventitious advantages count for little. The inheritance of such characters is probably more instructive when we are investigating the incidence of heredity than the history of families of great distinction. There is much material of this kind in the valuable but unfortunately very expensive periodical, *Biometrika*. Davenport gives some striking examples of the inheritance of stature and longevity,

which indeed we must have all observed. Insurance companies, it is well known, ask particularly about the ages at which the applicant's four grandparents died. In one American family mentioned by Davenport, the father died at 91, the mother at 82. There were 17 children, of whom the shortest lived died at 67. The inheritance of high stature cannot have escaped our notice. It would be quite easy to breed a family with an average height of over six feet by selected matings.

Mendel's discoveries have perhaps affected Galton's law of "reversion to the mean." Such reversion usually takes place, but if matings were selected with a view to preserving some particular character, I see no reason why it should not be firmly established. There is no tendency to breed out a degenerative variation which has once appeared, unless it kills off its victims.

HEREDITARY ABILITY.

Are some kinds of ability more strongly inherited than others? I believe myself that no kind of ability is more strongly inherited than that which leads to academic distinction in "humane letters," but that mathematical talent is comparatively sporadic. In classical scholarship the record of such families as Butler, Kennedy, Sidgwick is very remarkable. I gave in one of my books the history of my own mother's family, the Churtons. The first scholar of the family, my great-grandfather, was something of a freak, since his father was one of the old yeoman farmers, cultivating his own land. But as usual, for better or worse, the freak was persistent. In four generations no male of the family who lived to grow up failed to win more or less distinction as a scholar or theologian or both. There are 13 names in the list. Such records give point to the question of St. Paul, "What hast thou that thou didst not receive? But if thou didst receive it, why dost thou glory as if thou hadst not received it?" It would be a great comfort if we could apply the same argument to our faults. There are some professional families much more distinguished than mine, such as the Wordsworths, Selwyns, and Pollocks, whose history would be well worth tracing in detail. In fact, I believe that if, say, a thousand professional families would draw up records of this kind, it would have a real scientific value. I have suggested to the Eugenics Society that they might announce their willingness to receive family histories.

A very important question, especially as bearing on the subject of this lecture, is whether the professional classes have really a much higher average of innate ability than what, without meaning any offence, we may still call the lower middle and lower social strata. Political prejudices ought not to be allowed to interfere with a purely scientific question. The best discussion of the subject that I know of is in McDougall's "National Welfare and Decay." McDougall, who is now professor of psychology at Harvard, has a reputation second to none as an authority on social psychology. He considers that for the British people at the present time the topic of racial deterioration "overshadows and dwarfs every other that any man of science could propose for its consideration." "Both these great nations" (Britain and America) "are threatened by an insidious danger which, if we cannot learn to cope with it, will bring our brightest hopes to nothingness, and render our ideals merely the fleeting visions of a golden age which is past." The Great War has taught us that civilisation and culture do not necessarily sap the energies of man; this is a most reassuring discovery. Our future is in our own hands to make or mar. History seems to show that in the rise and fall of peoples economic factors are of secondary importance; no advantages will save a people from decay when it loses its natural superiority. Nations do not grow old like individuals; that is a false analogy; but they do die of disease, when the burden of civilisation becomes too heavy for the shoulders which have to bear it. This is why the present situation is so serious. The higher races and classes are using the resources of scientific knowledge to reduce the death-rate of the inferior and the birth-rate of the superior. In the United States a competent investigator says, "All available data combine to prove that the Anglo-American population has not merely attained its maximum, but has begun to decline." Prof. Karl Pearson, whom no one will accuse of being a Tory, says:—

> The upper middle classes are the result of a severe selection of capacity, and later, of intermarrying, under conditions which seem no longer possible. . . . It is the realisation of these points, that not all, but the bulk of the abler and more capable stocks have drifted into the upper middle class, and that ability is inherited, which makes, in my opinion, the decreasing relative fertility of these classes a matter of the most serious national importance.

This was written as early as 1905. In view of the financial burdens heaped upon the professional class since the war, it is certain that the situation has become very much worse. If you will take the trouble to open "Who's Who" at random, and count the number of children in 50 or 100 consecutive entries you will find that they are slightly less than two to each entry; so that these families of moderately successful men are not keeping up their numbers.

But have we any direct evidence that the children of the upper middle class are better endowed by nature than the other strata which, as we have seen, are crowding them out of existence? I will give two quotations from McDougall's book:—

> "Some years before the war, one of my pupils at Oxford made a direct attack upon the problem, and the results are significant, though on a small scale. At Oxford are gathered as teachers many men from the whole British Empire, highly selected in virtue of intellectual distinction. Now it so happens that in a certain private school in Oxford a majority of the boys are sons of these men. We therefore set out to compare the intellectual capacity of the boys of this school with that of boys of a primary school. This primary school was an exceptionally good school of its kind, the teaching being in many respects better than in the other, the private school; the boys were from good homes, sons of good plain citizens—shopkeepers, skilled artisans, and so forth—and there was no question of their development having been retarded by physical privations. Without going into detail, I may say summarily that the result was to show a very marked superiority in the boys of the school frequented by the intellectual class. The result is all the more striking if you reflect on the following facts: first, every boy has two parents and inherits his qualities from both. Secondly, it has not been shown that university dons prefer clever wives, or that they are particularly clever in choosing clever wives. It is highly probable that if the wives were all as clever as their husbands, the superiority of their sons would have been even more marked."

My other quotation concerns America.

> "Mr. A. W. Kornhauser examined 1000 children, drawn from five schools of the city of Pittsburgh. Of these schools, A and B were attended chiefly by the children of the poorer classes, largely unskilled manual workers; C and D by children of a more prosperous class, largely skilled artisans and small shopkeepers; E by children of parents in very comfortable circumstances. He found that the groups from A and B show a very large proportion of retarded, with an almost negligible number of advanced; C and D have the most nearly normal proportion of retarded and advanced; the E group shows a very small proportion of retarded, with a comparatively large percentage of advanced pupils. If the several schools had had the same standard of grading, the superiority of intelligence in the children of E over the others would be revealed even more strikingly. The figures are—in A, retarded 45·2 per cent., normal 47·1 per cent., advanced 7·7 per cent. In E 12·7 per cent. retarded, 62·7 per cent. normal, 24·6 per cent. advanced."

McDougall considers it proved that "the social stratification which exists in modern industrial communities is positively correlated with a corresponding stratification of moral and intellectual quality, or in less technical language, the upper social strata as compared with the lower contain a larger proportion of persons of superior natural endowments." He goes on:—

> "Forms of organisation matter little, the all-important thing is the quality of the matter to be organised, the quality of the human beings that are the stuff of our nations and

societies. . . . Civilisations decay because they die off at the top, because they cease to produce in sufficient numbers, men and women of the moral and intellectual calibre needed for their support. . . . The number of such persons is becoming absolutely fewer with each generation; the evidence is overwhelming."

I should not myself be quite so dogmatic as this last sentence; the question is too difficult to answer confidently. But several modern tendencies are actively dysgenic. The relative sterility of the professional class is a new thing. The sharp decline in the infant mortality of the slums is a new thing; the educational system whereby in each generation the cream of working-class ability is skimmed off and drafted into the infertile black-coat professions, is new; the feminist movement, which according to some is the most dangerous of all, by making the most intellectual women disinclined to marriage and motherhood, is new. The extent of the evil may be and has been very variously estimated; but beyond all question the classes which are the best endowed intellectually (and, in this country, the best endowed physically as well) are passing into a relative and even an absolute decline. At Oxford, McDougall found that 142 dons had 261 children—284 parents, 261 children. Taking the country as a whole, though the figures are somewhat contradictory, the lowest birth-rates seem to be those of the medical profession, the teachers, and ministers of religion. My present audience will probably agree that no more desirable parents of the next generation can be found than the members of these three professions. It may also suggest food for reflection that these three professions are the chief denouncers of birth control. We have seen what our leading authorities on Mendelism and Biometrics think of the immense importance of preserving the best stocks and repressing the increase of the worst. There is therefore grave reason for apprehension at the course which our civilisation is taking.

Before leaving the subject of good heredity, and passing to the darker side of my theme, I should like to call your attention to one of the most remarkable examples of the way in which a country may be permanently enriched by a very small accession of picked immigrants. To judge from the claims of some prosperous Americans, one might suppose that the *Mayflower* was as large as the *Olympic*. In point of fact, it was a very small vessel, and the mortality among the Pilgrim Fathers was so great that only 33 of them founded families. Nearly half the great men of America are the authentic descendants of these 33 men. Here is the list, as furnished to the last Congress of Eugenics :—

John Adams, President; John Quincey Adams, President; C. F. Adams, Ambassador to Great Britain; H. Dearborn, Secretary for War; Garfield, President; Ulysses Grant, President; L. P. Morton, Vice-President; Elihu Root, Secretary of State; A. Taft, Attorney General; W. H. Taft, President; Zachary Taylor, President; E. B. Washburn, Secretary of State; Daniel Webster, Secretary of State; L. Wood, Governor of Cuba and the Philippines; Lord Lyndhurst, Lord Chancellor of England; M. W. Fuller, Judge of the Supreme Court; W. C. Bryant, Poet; W. Churchill, Novelist; R. W. Emerson, Philosopher; H. W. Longfellow, Poet; with many other names less well known on this side.

IMPAIRMENT OF THE NATIONAL STOCK.

I now come to the injury which is being done to the national stock by the unchecked propagation of inherently bad stocks. A combination of socialism in distribution with laissez faire in procreation is a policy only fit for Bedlam. The importance of prenatal infection is often exaggerated, partly for moral reasons. I once asked Sir Conan Doyle whether as a doctor he could justify the plot of his lurid story, "Unto the Fourth Generation," and he admitted that he could not. It seems very doubtful, in spite of the researches of my friend Dr. Mjoën, of Norway, whether alcohol injures the germ-plasm. Sir Archdall Reid even suggests that after a century or two of prohibition a nation would be in an admirable state for general alcohol poisoning; the effects of immunisation would by that time have worn off. The danger to the stock comes from those diseases which when they have once appeared in a family, Mendelise, and are never bred out of it, though the curious law of "antedating," which seems to be established in some cases, looks like an attempt of nature to cut off the tainted entail.

I will take first the case of mental defect. The feeble-minded are about 50 per cent. more prolific than the normal. The researches of Tredgold are decisive on this point. Where two feeble-minded persons marry, the children are all tainted. Pedigrees may be found in Tredgold, Whetham, Davenport, and many other writers. In one family tree, planted by two defectives, there are 14 names, none of them normal. Holmes says :—

"Out of 482 children recorded by Goddard as arising from unions between two feeble-minded persons, 477 were known to be defective. . . . In 41 such matings of the 'Kallikak' family, there were 222 feeble-minded and only 2 normal."

Where one parent is epileptic and the other feeble-minded, Davenport and Weeks found that in 15 matings, 28 out of 55 children were epileptic, 26 feeble-minded, and 1 insane.

Insanity is, of course, a word which covers many diseases, and I am not suggesting that all insanity is degenerative. But it is ominous that—

"in 13 years before 1903 the insane in institutions in the United States increased 100 per cent., and that since 1859 in England and Wales the insane have increased 230 per cent." (Holmes).

These figures do not include the mentally deficient, who have multiplied as we should expect.

It is not generally known that though the death-rate has declined rapidly and steadily till it must have almost touched bottom, the saving has been entirely in the earlier periods of life. The expectation of life at 60 is, I believe, no higher than it was 70 years ago. Some microbes seem to be in process of establishing a *modus vivendi* instead of a *modus moriendi* with their hosts, but cancer begins after 45 to levy a cruel toll upon both sexes, and now nearly equally, though it was formerly more fatal to women in the proportion of 5 to 2.

Some of the most striking instances of heredity in disease are in somewhat rare ailments, which have not very much racial importance. The incidence of albinism is so curious that it probably results from a combination of two or more factors. In one family there were 19 albinos out of 75 in four generations; but it seldom appears so frequently as this. Night-blindness and colour-blindness are both, it seems, inherited with a greater intensity than can be accounted for by Mendel's law. Two marriages between deaf mutes produced nine children, all deaf and dumb. A third marriage between two deaf mutes produced four children, all deaf and dumb; but one of them married another deaf mute, and had two normal children. Hæmophilia is usually supposed to be absolutely sex-linked; for which reason I should be interested to know why the Registrar-General passes, apparently without investigation, the attribution of a few deaths of females to this cause.

A more interesting question for most of us is whether the national physique is improving or deteriorating. A Danish savant proved at the last Eugenics Congress that the stature of Danes has risen very appreciably in 50 years, the figures being 165·42 cm. in 1852–56, and 169·11 cm. in 1904–05. The average height of the Dutch has risen from 165·5 cm. in 1866 to 168 in 1899. In France the average height of women is said to have risen 3 cm. in 80 years. The only English figures of the same kind that I know of are measurements at Marlborough College, which showed, in boys between 14 and 15, an increase from 61·4 inches in 1874–78, to 61·96 in 1899–1902.

It is difficult to reconcile these favourable statistics with an article published last year in the *English*

Review, giving very disquieting figures about our own country.

Grade A 1917–19.	Average.	Whole country 1883 (Anthropometric Committee of Brit. Assoc.).
Height, 66 in.	65·7	67·4
Chest, 34 ,, ...	32·5–33	36·4
Weight, 130 lb.	128·4	148·7

In boys of 18 the height is said to be less by 1·6 inches, the chest by 0·3, the weight by 11·6 lb. The same article states that in 1924 the Commissioners of Constabulary reported a general deterioration in the nation's physique. The chief constable is lucky if he finds five suitable men among a hundred applicants.

I should be much interested to know whether the facts in this article have been challenged. If they are true, they are, it seems to me, exceedingly serious, especially as our neighbours on the continent do not appear to be suffering in the same way. The decline is far too great to be attributed to malnutrition during the years of the war.

There is another way, besides dysgenic selection, in which the national stock may be impaired. Nature, we were told long ago, takes away organs which are not used. I suppose the statement is broadly true, whatever the method may be. The free-moving creature which becomes a parasite drops all its organs except those which enable it to hang on and suck. In one of the most interesting books of recent years, "Social Decay and Regeneration," by Austin Freeman, which I have already quoted, the thesis is maintained that the invention of the power-engine marked an epoch in the history of mankind. Ever since the growth of the machine age there has been a destruction of natural beauty, a reckless squandering of irreplaceable natural resources, and a progressive loss of all the exquisite works of skill wrought by the human hand. The old handicraftsman was in every way a superior and more civilised animal than the minder of machines. Machinery has transformed a skilled into an unskilled population. The modern workers are parasitic on the machine which has ousted them from natural human occupations; apart from the machine they would be helpless even in the presence of abundant material; a company of such men, left to themselves, would either perish or exist miserably as savages. Together with this disastrous change we see the growth of anti-social movements; we see hatred of civilisation itself; we see whole classes banded against society, and determining to be parasitic upon it; we see increasing multitudes accept permanently the position of pure parasites—dole-receivers; we see the industrious producers harassed and plundered more severely every year. This picture is filled in with a great wealth of detail. The indictment is very difficult to rebut; and the diagnosis is the more grave because the disease seems to be constitutional, the inevitable result of changes which could not be resisted. Society may become like the majestic sunfish—its scales covered with lice, its intestines one tangled mass of tapeworms, its eyes pierced by trematodes, no organ of its body free from swarming masses of parasites. And it may not be easy to recall the parasites to healthy social habits. *Facilis descensus Averni ... sed revocare gradum ... hoc opus, hic labor est.*

CONCLUSION.

Nevertheless, I am inclined to think that it is not too late to stop the mischief, which has not yet had time to go very far. We must hope that social antitoxins will somehow be generated, and that we shall not steer the ship upon the rocks with our eyes open. We are not yet a degenerate people; we are a race to which any man might be proud to belong. But we are not at present in a healthy condition, and unless we take the problem of racial decay in hand promptly it may be too late. I only wish I had more practical suggestions to offer. Mr. Austin Freeman attempts some at the end of his book, but they seem to me very impracticable. All we can do at present, I think, is to persuade our countrymen what the pressing problems really are. They are so very different to those in which our precious politicians interest themselves.

The great medical societies can do much, if they will speak out. I do not think they quite realise how glad the public would be to listen to them. The modern man may deny that he has a soul, and forget that he has a mind; but he is acutely conscious that he has a body, and therefore he has a great respect for the doctors. I wish they would testify, for I nearly always agree with them.

TWO PAPERS ON

BRONCHIECTASIS:

RECENT ADVANCES IN TREATMENT AND DIAGNOSIS.*

I.—FROM THE MEDICAL ASPECT.

BY CLIVE RIVIERE, M.D., F.R.C.P. LOND.,
PHYSICIAN, CITY OF LONDON HOSPITAL FOR DISEASES OF THE HEART AND LUNGS AND EAST LONDON HOSPITAL FOR CHILDREN.

BRONCHIECTASIS, if we may call it a disease, is certainly a very protean one; as varied, indeed, in its clinical manifestations and therapeutic demands as is pulmonary tuberculosis itself. This is understandable when one recognises that its essential quality—bronchial dilatation—is the end-product of a multitude of disease processes; that it may attack many or few bronchi, and these of various sizes; that it may be unilateral, or affect both sides of the chest; that the surrounding lung may be healthy, inflamed, or fibrosed; and also that the dilated tubes themselves may remain comparatively healthy, be subject only to catarrh, or may be the seat of a severe suppurative process. It is this last condition, bronchiectasis with suppuration, which I think we must have especially in mind in our discussion to-night, since it is here that diagnosis and treatment are in most urgent demand, and here, consequently, that new methods have arisen and demand our consideration.

For our present purpose, I think, cases of clinical bronchiectasis may be said to fall into two main groups: 1. The slighter cases, especially seen in childhood, mostly involving small bronchi or bronchioles, and with mild or intermittent symptoms. 2. The more serious cases, mostly found in adults, though frequently originating in childhood, where symptoms are continuous and severe (though often with intermissions at first), and where the condition finally amounts to a suppuration within the dilated and thickened tubes. A third place might be given, perhaps, to certain cases of lung suppuration where bronchiectasis is an accompaniment of abscess formation, the result, in most cases, of aspiration of a foreign body, generally broken tooth, wool plugs, or septic materials, during a tonsillectomy or tooth extraction. These cases of "bronchiectatic lung abscess," as they have been called, are so important in practice that they may well be included in our present discussion, since bronchiectasis is one of their features.

Now before I turn to the serious cases of bronchiectasis with suppuration, which I take to be our main thesis, I should like, if I may, to say a few words about the cases of slighter disease. As a physician attached to a children's hospital I am brought in contact with numbers of these cases, and my first interest in bronchiectasis was aroused by them to the extent of collecting and publishing a paper on 40 cases as long ago as 1905. Their importance lies in the fact that they are potentially serious, that their recognition and study may give the clue to adult chest disease, and that they help us to understand how bronchiectasis is brought into being. Often it is possible to detect dilatation of bronchioles

* Opening a discussion on Nov. 22nd before the Medical Society of London.

after an attack of broncho-pneumonia, and to watch the child through subsequent attacks into a condition where a permanent fibrosis and bronchiectasis is left at the lung bases, generally more marked on one side than the other. The symptoms of these cases, and the severe catarrhal attacks to which they are subject often, I think, where the structural changes are moderate, abate with growth, and hence a proportion of these cases drop out of view, and only the more serious ones carry their disability visibly into adult life. This accounts, I think, for the fact that these cases if looked for are observed more commonly in the first decade than at any subsequent period, though presenting for the most part much less serious symptoms. The slighter of them are mainly of importance in that their physical signs may form the basis for a mistaken diagnosis, and that they may appear in adult life, the childhood condition being forgotten, under such guises as basal bronchitis, purulent bronchitis, and broncho-pneumonia in the adult, or with such unexpected symptoms as blood-stained sputum, or even a frank hæmoptysis. This condition of "damaged lung" is generally basal in the broncho-pneumonic areas, but it may, rarely, follow an upper lobe pneumonia, generally on the right side, and is then very apt to be mistaken for pulmonary tuberculosis. How far modern methods, such as lipiodol, will come into use in the differential diagnosis of these slighter conditions it is difficult to say.

More serious examples of bronchiectasis, those indeed which mainly concern us to-night, may begin in childhood, and only become serious with the passage of time, or may arise in adult life from causes often somewhat obscure. On the one hand, they may arise from inflammatory conditions which weaken the bronchial wall as from bronchial suppuration, or influenzal congestion or pneumonia, a common cause in recent years. They may develop also as a result of pulmonary fibrosis. On the other hand, serious bronchiectasis may be due to bronchial obstruction, whether within, from foreign bodies, or strictures, congenital or syphilitic, or from pressure without by neoplasm, aneurysm, or diseased glands. Under all these circumstances the symptoms and severity of the case vary greatly with the following conditions: (1) the amount and nature of the bronchial dilatation; (2) the adequacy of drainage; and (3) the severity of the infection present in the deformed tubes. With regard to (1) and (2), it is obvious that, on the one hand, an area of dilated bronchioles will be of no great consequence unless as a nidus for catarrhal attacks, whereas a lobe riddled with thick-walled dependent cavities, insufficiently drained by a narrowed bronchus, is likely to prove a very different proposition. But it is the nature of the infective process which especially determines the course, whether serious or otherwise, of the case. Even with considerable bronchial dilatation a patient may be kept in comparative health and comfort for an almost indefinite period, providing no severe infection of the unhealthy area arises. Owing to imperfect drainage a condition of chronic catarrh is maintained, sputum is probably abundant, and if treatment is neglected, perhaps occasionally offensive, but health may be fairly maintained and the expectoration remain the patient's chief trouble. But replace this catarrhal condition with a severe suppurative process and the case enters a different category. Bronchial drainage may altogether fail to relieve, and surgical intervention appear necessary to treat what is, after all, a surgical disease, though invading the lung, one of the last strongholds of the physician.

Diagnosis.

In the diagnosis of bronchiectasis two recent advances claim special notice—namely, bronchoscopy and the injection into the bronchial tubes of substances, such as bismuth and iodine preparations, which are opaque to the X rays.

Bronchoscopy.—The increasing use of the bronchoscope in the differential diagnosis of bronchiectasis may be traced to the activities of the American school, notably to Chevalier Jackson. In the elimination of foreign body, or of stricture, or obstruction as a cause (with due care in the avoidance of its use in cases of aneurysm), and in the determination of the extent and location of the trouble, the patency of the affected bronchus, the presence of granulations, &c., this method becomes of increasing importance. Bronchoscopy has become in America a specialty apart from laryngology, due, no doubt, to that curious foreign-body-in-a-bronchus habit of the American people, and has reached a stage of skill where no more than a local anæsthetic to throat and epiglottis is generally needed for its use, even in childhood. W. F. Moore, of Philadelphia, treating 38 cases of bronchial suppuration by weekly aspiration and lavage, was able to record that, though no general anæsthetics were used, not one case refused to carry through the course of treatment.

Bismuth and Lipiodol, &c.—At the end of a bronchoscopic examination it has been the practice of Chevalier Jackson to insufflate bismuth and radiograph the chest. Where the bronchoscope is not in use the simplest plan is to inject 20 c.cm. of lipiodol through the crico-thyroid membrane following anæsthetisation of the trachea with some 5 per cent. cocaine. If a needle only three-quarters to one inch long is used, the warmed lipiodol is easily injected under hand pressure without the screw arrangement often recommended. The needle must be kept sharp or the tracheal mucous membrane may be pushed before it. At any rate, I have seen failure to reach the tracheal lumen and that seemed the only possible explanation. I shall not here deal with lipiodol in diagnosis since I know it will be adequately discussed by others. All I would like to insist on is the useful attention it is directing to the value of postural X ray examinations now fluid levels can be so easily followed, and also to the occasional value of the lateral, as opposed to the oblique radiogram in diagnosis. In addition, it is interesting that lipiodol shadowing is visible in some cases as long as four months after its introduction, and that Forestier, of Aix-les-Bains, holds that remedial effects follow its use in bronchiectasis. These are points for further investigation. It will be remembered that intratracheal injection, mainly of menthol and guaiacol in oil, formed a treatment of the past, but was not followed by any very striking results.

Conservative Treatment.

In the days when the chest was still the undisputed property of the physician, before ever the surgeon began to look in at the door, cases of bronchiectasis, treated on common sense lines, often did remarkably well, and they still continue to do so. But recently I have been shocked to see, in an article on the treatment of bronchiectasis by a distinguished surgeon, under the subheading Medical and Hygienic Therapy, the words "This is without effect." Evidently it is time for the physician to reassert himself! In practice one may say, I think, that the ordinary treatment used by physicians in the more recent past, if persisted in by the patient, gives adequate and satisfactory results in a majority of cases. It is well to recognise at the outset that the anatomical condition bronchiectasis, once established, is incurable, but that nevertheless good health may be maintained in many cases in spite of it. It must not be supposed that removal or elimination of the diseased area is necessary or possible except in a few cases, and the number suitable for surgical measures is really comparatively small. Even the surgeons, as a rule, display no undue enthusiasm. Hedblom, of Rochester, U.S.A., refers to these cases as "the most thankless task in surgery." Sauerbruch, who had operated on 69 cases up to 1920, says "The surgical treatment of bronchiectasis is the most difficult and thankless chapter in the whole of lung surgery." Evarts Graham, whose surgical work in bronchiectasis we shall mention later, finds that he operates on fewer and fewer cases; he was content to treat 24 of 40 cases in children by ordinary conservative measures. These measures must now be referred to.

Postural Drainage and Creosote Chamber.—Only two of them are of outstanding importance, and we may let the rest go by the board to-night. I refer to postural drainage, and the creosote chamber treatment introduced by Arnold Chaplin in 1895. With these two properly applied, where bronchial drainage is free, we can bring to clinical recovery and keep in comparative health the majority of cases of bronchiectasis, and that without danger to life. Unfortunately, human nature being what it is, it is very difficult to avoid relapses through neglect of treatment. Life, as we know too well, is apt to become as years advance "just one darned thing after another" and it is scarcely surprising, perhaps, that patients resent, and after a time neglect, any addition to the daily ritual. Other methods of treatment, including surgical measures, come into consideration only where postural treatment and creosote chamber fail or are inapplicable, or where the patient demands some release, even at danger to life, from the burden of a somewhat hampered existence. Then must we consider, one by one, the means which modern progress has prepared for us. Let us take a problematical patient and consider the lines on which we should deal with him.

Often we find our patient propped up in bed and overflowing with secretion like a full jug. He has avoided movements which bring on cough and so his secretion has accumulated. The first process will be to empty him out gradually till he can lie flat, and thereafter, as his condition allows, begin postural drainage in the knee-elbow position, and later over the side of the bed, and, presently, if the case appears to be an ordinary bronchiectasis, the creosote chamber. In the meanwhile radiograms will be obtained whereby we can ascertain where the trouble is situated, whether there is any question of neoplasm, aneurysm, foreign body, or abscess formation, what amount of fibrosis is present, and, if necessary, with the assistance of lipiodol, what is the nature of the bronchiectasis, and how far, if at all, it affects the opposite lung. For of 318 cases observed in the Rochester Clinic, U.S.A., 28 per cent. were bilateral, and in another 38 per cent. the condition of the second lung remained uncertain. Among 54 autopsies in bronchiectasis Lebert found 52 per cent. unilateral and 48 per cent. bilateral.

Now under postural drainage and creosote vapour in many cases the sputum will lose its offensive odour and much of its purulent character, and become greatly reduced in volume, the patient's toxic condition will clear up, and an extended trial of these measures will be indicated, especially if disease is bilateral. If, however, there is question of a foreign body or of abscess formation, or the symptoms date from an operation, especially a tooth extraction or tonsillectomy; if there is suspicion of bronchial obstruction other than aneurysm; or if drainage seems hampered and the sputum remains offensive, and general improvement is slow, then a bronchoscopic examination may help to clear up both diagnosis and treatment.

Bronchoscopic Treatment.—The bronchoscope in diagnosis we have already mentioned; it may also be helpful in treatment. Foreign bodies may be found and removed, foul pus evacuated by aspiration, strictures dilated and granulations cauterised. Weekly bronchoscopic aspiration, assisted in some cases by lavage and medical applications to the bronchial walls, has proved of value, especially if used early (T. McCrae)—it will not, of course, cure chronic bronchiectasis any more than will postural or any other form of drainage, but it will help to restore health. Nevertheless, among W. F. Moore's cases of bronchial suppuration so treated a third showed no improvement. "The unimproved class," he remarks, "was chiefly made up of patients with extensive bronchiectasis." Thus a proportion of cases will be left for the trial of other more radical measures.

More Radical Methods of Treatment.

These have for aim the development of one or more of the following principles: (1) Improvement of drainage. (2) Closure of suppurating cavities by collapse or compression of the surrounding lung. (3) Extirpation of the diseased area. These further measures are all, except external drainage, of modern development, and may be considered under the following headings: pneumotomy, artificial pneumothorax, phrenic exairesis, thoracoplasty, ligature of pulmonary artery, and lobectomy and cautery lobectomy.

Pneumotomy.—External drainage has been attempted in the past, and mostly abandoned for ordinary bronchiectasis since a single opening fails to drain multiple cavities, and may greatly interfere with the efficacy of cough in clearing the chest. Only where suppuration has gone on to softening and the formation of a single large sac, a bronchiectatic abscess, is open drainage likely to prove successful, and such an opening, unlike that for simple abscess, will not again heal spontaneously. Nevertheless, the improvement which follows in suitable cases may reconcile the patient to the inconvenience of an open fistula which at a later stage may require but a single dressing daily. Such a fistula can be closed at a later date, though this is, probably, seldom advisable, or further operative measures may be added. Sauerbruch, collecting the literature up to 1911, found 123 pneumotomies recorded with results: 33 per cent. cured, 6 per cent. improved, 27 per cent. unrelieved, and 25 per cent. dead. The results in the hands of different surgeons differed widely, probably according to the suitability of the material chosen for the operation, some achieving great success and others decidedly the reverse. It seems probable that a proportion of the successful cases were lung abscess rather than bronchiectasis, since little trouble has been taken in many quarters to differentiate between these two conditions. Clearly the success or otherwise of external drainage is bound up especially in the recognition of the suitable case.

Artificial Pneumothorax.—This treatment, whose purpose is the closure of the suppurating cavities by collapse or compression of the lung, can only come into consideration when disease is wholly or mainly unilateral, and even then it is open to certain serious difficulties.

1. When one considers the post-mortem appearances of the disease it is obvious that in a majority of the bad cases no real collapse of cavities is possible, and this is found to be the case in practice. Pneumothorax is best suited to certain post-pneumonic cases in developing stages—that is, in early life—since in these the smaller and thin-walled bronchi are at fault. It is but little applicable to the old advanced cases of adult life where the larger tubes are affected, and these are the very cases for which treatment is especially needed.

2. For the reason just given only a very complete collapse is likely to succeed and this is just what, in bronchiectasis, is very rarely attainable. Adhesions are generally numerous and strong, and Burrell records good collapse in but two among his 19 cases. Now the presence of these adhesions brings us to the third difficulty.

3. Are they not themselves evidence that a spread of infection to the pleura is common in these cases, and such a pleural infection occurring after the lung is collapsed means a pyopneumothorax of almost certainly fatal issue? This has happened in my own practice, and I have become very cautious of advising pneumothorax on this account. Still, the treatment is probably, in spite of this risk, the best that can be done in certain cases, especially in early life, and if complete collapse is attained the risk of pleural infection may be much diminished thereby. It must be remembered that pneumothorax treatment is in this disease only palliative, and that the cavities reopen if the lung is allowed to re-expand, though the suppurative process may by then be mitigated or suppressed. In gauging the effects of pneumothorax on the bronchiectatic area it is useful, as is well shown in some plates published by Burrell and Melville, to inject lipiodol into the lung before the pneumothorax is initiated.

Phrenic evulsion or exairesis has been used of recent years in the treatment of basal bronchiectasis. The paralysed diaphragm rises into the chest and the base of the lung collapses, the effect being especially pronounced where the right nerve is treated. It might be thought that expectoration would be thereby hindered, but in practice the opposite generally occurs. Thus among 40 cases operated on in the Sauerbruch Clinic, Lange found that in 23 expectoration was facilitated, in eight there was no change, and not one complained of difficulty. The explanations suggested by J. Alexander for this improved power of expectoration is that the abdominal muscles during cough can exercise a more direct propulsion on the lung through the paralysed diaphragm. Cases have been reported where phrenic evulsion has led to improvement in bronchiectasis, but personally I have not been impressed in the cases where I have tried it, nor can it be expected to accomplish very much.

Thoracoplasty.—Paravertebral thoracoplasty, performed with such success in selected cases of pulmonary tuberculosis, has proved much less valuable, as would be expected, in bronchiectasis. Here the thickening and stiffness of the bronchial walls, and often of the surrounding lung, prevents closure of the cavities even under pressure by a pneumothorax, and mere reduction of lung volume by thoracoplasty will effect even less. Among 27 cases of disease involving the whole of one lung operated on by Sauerbruch, none were cured and only five permanently benefited. There was only one death among these cases. On the other hand, he records better results in a further 11 cases where the trouble followed empyema and was confined to the lower lobe. More recently Hedblom has treated ten cases, with no death and with considerable improvement in most, by a more extensive but graded thoracoplasty confined to the lower part of the chest. The operation is done in four or five stages under local anæsthesia and the outcome is the removal of practically the whole of the fourth or fifth to eleventh ribs, beginning with the paravertebral region, continuing with the sternal ends, and finally removing the mesial portions. The collapse is thus rendered very complete, but his patients, he says, are up and out of bed two or three days after each operation; nor has he anything to say about "flapping" or "fluttering" of the mediastinum, which was so serious a feature of the extensive Brauer-Friedrich operation of old days. This is probably avoided by the multiple-stage procedure, but it is difficult to suppose that many patients in this country could be induced to undergo five resection operations under local anæsthesia. A thoracoplasty adequate to the improvement of bronchiectasis must necessarily be a severe operation, and personally I feel there are very few cases where it seems justified or necessary. I confess that I have always so far offered it to my patients in such guise that it has invariably been refused, and on each occasion I have felt definite relief at the outcome. A reduction of sputum, which can generally be achieved by other measures, seems hardly a sufficient reward for this operation, and the really septic cases are hardly fit subjects for it. In combination with other surgical measures, however, rib resections may prove of decided value.

Ligature of the pulmonary artery or its branches does not seem to be a very difficult operation apart from the presence of adhesions. Its effect is to cause a fibrosis and shrinkage of the lung or lobe, and this so marked that in some cases a subsequent rib resection has seemed advisable. It has also been done as a preliminary to lobectomy. It was performed by Sauerbruch in 14 cases of bronchiectasis with no favourable results, and with no obliteration of the cavities. This seems to me the logical outcome, since pulmonary fibrosis itself leads to bronchial dilatation. There seems no place for this operation by itself in the treatment of bronchiectasis.

Lobectomy and Cautery Lobectomy.—Extirpation of the diseased area makes a natural appeal to the surgical mind, and it was inevitable that attempts at this should be made in selected cases of bronchiectasis. Unfortunately, the mortality for lobectomy, 52 per cent. among the 48 reported cases, has proved too high to encourage its further use. Most of the deaths were due to infection of the raw surfaces exposed during the separation of the practically always adherent diseased lobe or lung. To avoid this risk, Evarts Graham, whose name is well known to us in connexion with diseases of the gall-bladder, has since 1923 been urging the piece-meal removal of the bronchiectatic areas by means of the actual cautery. This is no new operation—Sauerbruch, in 1920, records having performed it in nine case, in five with decided and two with slight benefit, and with two deaths. Graham's claim for it is the establishment of numerous bronchial fistulas for massive drainage, by opening the lung tissue over a wide surface; the compression of the diseased area by packing and bandaging; and eventually the removal of more and more lung up to extirpation of the bronchiectatic lobe. This method, he claims, "combines the three cardinal principles of the surgical treatment of chronic pulmonary suppuration—namely, drainage, compression, and extirpation." The ribs are resected over an area about 4 inches square, the parietal pleura is exposed by stripping off the periosteum with the muscles, vessels and nerves, the pleural surfaces are examined to see if they are adherent, and if not steps are taken to make them so. This is the first stage of the operation. A few days later cauterisation is begun with a large soldering-iron heated to redness; a wide cross section is destroyed, so that when the slough separates some 20 or 30 bronchial fistulas are seen exuding pus; no anæsthetic may be needed at this and subsequent stages. Drainage is assisted by the use of suction apparatus. After about three weeks a second cauterisation is made, and this is repeated at intervals till the diseased area is virtually destroyed, from one to seven or eight cauterisations being needed in different cases. Hæmorrhage is controlled by packing which Graham has found to suffice even when large branches of the pulmonary artery are opened. No shock follows these operations, but fever and malaise often appear on the third day and persist till the slough separates on the tenth to twelfth day. Eventually the bronchial fistulas heal, or if open are found to supply about the same secretion as will a normal nose.

The obvious dangers of this operation are *air embolism* and *hæmorrhage*. Air embolism is indeed a danger in all operations for bronchiectasis owing to the inability of cut veins to collapse in the thickened tissues. Sauerbruch has recommended differential pressure apparatus for its avoidance. No less than three of the four deaths among Graham's first 20 reported cases were from cerebral complications, and two of these were almost certainly air embolism. Among his latest figures cerebral embolism was responsible for four among seven deaths in 31 cases. Graham curiously enough had no serious cases of hæmorrhage, and none of post-operative hæmorrhage. On the other hand, Hedblom, among only four cases, experienced severe hæmorrhage in three, and two of these died of it, one on the seventh day during the changing of a packing. Graham remarks that hæmorrhage should be easy to control, since the pressure in the pulmonary artery is only 15–20 mm. Hg. If it proves severe he stops the operation, packs, and removes the pack on the third day, repacking if necessary.

Among the 31 cases operated on by Graham up to 1925 55 per cent. were reported well (36 per cent. still with open fistula), 13 per cent. markedly improved, 6·5 per cent. were recent cases and the results unknown, 22 per cent. (seven cases) were dead. On looking through the case-notes one is struck with the fact that the majority were cases of lung abscess and but few of simple chronic bronchiectasis. The method seems applicable for any localised area of suppuration within easy reach of the surface, but less so, it seems to me, in the ordinary basal bronchiectasis. When one considers how these elongated cavities abut on

the diaphragmatic surface it is difficult to see how the cautery can destroy them without considerable danger of wounding neighbouring structures, such as the diaphragm or the pericardium. It will be interesting to hear what our surgeons have to tell us about the technical possibilities of this operation in bronchiectasis.

Summary.

Our present position, then, with regard to the treatment of bronchiectasis may, in my opinion, be stated as follows:—

1. It is best, as a rule, to be satisfied with a moderate result—that is, with relief of dangerous symptoms such as can be accomplished in most cases by well-applied postural drainage and creosote chamber, assisted by drugs, and reinforced, if necessary, by bronchoscopic treatment. This applies especially to bilateral cases.

2. If these measures fail, something further may have to be tried, and its success will depend on the suitability of the method to the type of case. Thus (*a*) pneumotomy is suitable for single large suppurating cavities and for little else. (*b*) Phrenic exairesis may partly eliminate, and assist drainage in, a strictly basal lesion and is indicated for such. (*c*) Pneumothorax and thoracoplasty should be reserved for unilateral cases in which the lung and the cavities seem likely to be collapsible. (*d*) Lobectomy and cautery lobectomy can only be considered for well-localised areas of disease. The latter operation, however, seems materially to enlarge the scope of the older pneumotomy, and to offer external drainage at least to a much greater number of cases. Finally, it may be noted that under some conditions a combination of two or more methods may best meet individual needs.

Anticipatory Treatment.

Before concluding my paper I should like to say a few words on prevention, or what I shall call here "anticipatory treatment," because it is very germane to our subject, and recent work is bringing one aspect of it into prominence. I shall not here speak of means for avoiding the exacerbations so common in bronchiectasis in its earlier stages, but confine myself to one point—namely, the dangers of bronchial aspiration. First, there are the cases, all too common, of bronchial suppuration, and later bronchiectasis, caused by aspiration of broken teeth, cotton-wool plugs, and the like, especially after tonsillectomies and tooth extractions. Secondly, there are the cases where bronchiectasis or "damaged lung" is already present, and where a severe or fatal lung suppuration follows operation, rightly considered necessary, for chronic infection in the throat, nose, or nasal sinuses. Such a result is due to aspiration of septic material during anæsthesia, and the same may happen also from septic mouth secretions or vomit during operations in other areas. Now recent work has shown how easily aspiration of mouth secretions occurs under general anæsthesia, and how frequently post-operative lung conditions are due to this cause. Where there is a bronchiectatic or damaged lung such aspiration is, of course, especially dangerous. Hölscher showed by the use of gentian violet that the râles developing during ether anæsthesia were due to aspiration of the mouth secretion, and not to bronchial irritation and secretion caused by the gas. Myerson, examining patients after tonsillectomy under light anæsthesia with a bronchoscope, found that 90 per cent. of cases where the cough reflex was lost had aspirated mucus into the tracheo-bronchial tract. Lemon, of Rochester, working with a barium mixture coloured by gentian violet, found, in dogs, that if the head was raised bronchial aspiration occurred whether anæsthesia was light or deep, and that the suction pump failed to prevent it. Where the horizontal position was used aspiration was less, and diminished steadily as the Trendelenburg position was approached. Similar aspiration must probably take place, also, where the protective mechanism breaks down under severe illness, delirium, or alcoholic intoxication, and especially where vomiting occurs. The means of avoidance lie, of course, in posture, in the maintenance of a head downwards position under all these circumstances until the cough reflex is again fully established, and I think we who see these chest conditions should broadcast this danger to all those who may be responsible for these happenings. Should bronchial suppuration follow the aspiration of septic material under an anæsthetic it is stated by Willy Meyer, of New York, that bronchoscopic aspiration at an early stage, combined if necessary with lavage, will bring such cases to cure, even where abscess formation has occurred.

At the conclusion of this paper I should like to record my admiration of the work being accomplished in chest surgery, and especially in the treatment of pulmonary suppuration, at the present time in America. Team-work and coöperation are the basis of this work; an enlightened coöperation of the physician, surgeon, radiographer, and bronchoscopist, for in America, as I have already remarked, bronchoscopy has become a specialty all to itself. They hold over there, and I think they are right, that such team-work is a more rational proposition, and will give superior results, than the "physician-surgeon" idea which is evolving in the Scandinavian countries, and in one centre at least in Germany. Where we cannot here even boast of a section devoted to chest disease as a whole, they have an "Association for Thoracic Surgery" with membership of 100, and an annual meeting whose transactions are always full of interesting and enlightening material. Pulmonary tuberculosis is not excluded from their programme, and here again I think they are right. Now that the interests of tuberculosis as a whole are being well-attended to, it is fitting that its problems as a chest disease should receive special consideration at the hands of chest physicians and surgeons. A society, or at least a yearly congress for the study of chest disease as a whole, embracing physicians, surgeons, laryngologists radiologists, and anæsthetists, seems to me greatly needed in this country, and only thus, in my opinion, will any real progress in this branch of disease be brought about in the future.

II.—BRONCHIECTASIS FROM THE SURGICAL ASPECT.

BY J. E. H. ROBERTS, M.B., B.S. LOND., F.R.C.S. ENG.,

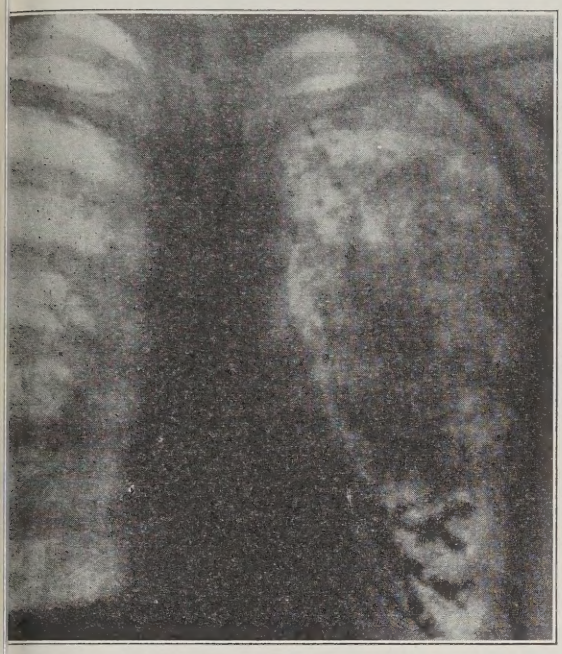
SURGEON WITH CHARGE OF OUT-PATIENTS, ST. BARTHOLOMEW'S HOSPITAL; SURGEON, BROMPTON HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST.

THE surgery of pulmonary infections, more especially of bronchiectasis, is still in the stage in which abdominal surgery was 30 or 40 years ago. By that I mean that the surgeon does not as a general rule see such cases until the condition has been in existence for a considerable time. Until the larger, as well as the smaller, bronchi are affected, their walls dilated, made rigid by fibrous tissue, and anchored by more fibrous tissue existing in the tissues outside them. Until the patient is enfeebled by long-continued toxæmia, loss of sleep from constant coughing, recurrent hæmorrhage, and in some cases by amyloid disease. Under such conditions it is matter for surprise, not that surgery does not produce better results, but that it produces results as good as it does. I hope that one result of such discussion as this will be a closer working together of the physician and surgeon at a much earlier stage than is as yet common.

Diagnosis.

The diagnosis is the field of the physician. It is in many cases difficult, especially in the upper lobe and in the earlier stages. The physical signs may be those of chronic bronchitis, or of pulmonary tuberculosis. In cases of bronchial obstruction by new growth or foreign body, the diagnosis is often not made until a late stage. It was said to me only a few years ago by a leading physician that it was

FIG. I.

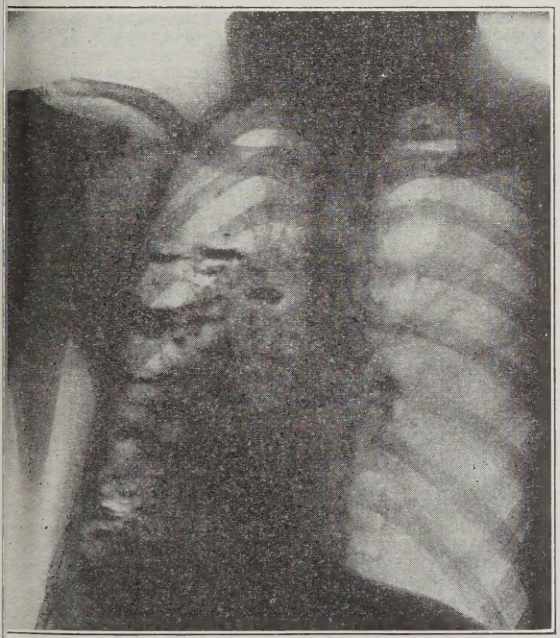


piodol radiogram demonstrating dilatation of bronchi of lower
)e. No lipiodol enters the alveoli through the dilated bronchi.
Patient recumbent.

FIG. II.

Lipiodol radiogram demonstrating sacculation of bronchi in lower lobe. Patient recumbent.

FIG. III.



ipiodol radiogram demonstrating multiple sacculation in whole right lung. Fluid levels well shown. Patient erect.

FIG. IV.

Lipiodol radiogram from same case as Fig. III. 8 days later, showing some dilatation and sacculation of bronchi of left lower lobe. Some lipiodol is retained in the cavities of right lung. Patient recumbent.

not possible to diagnose bronchiectasis until the physical signs of a cavity were present. To-day there are two methods which give great aid in the exact diagnosis. The older is direct bronchoscopy by which, first, bronchial obstructions may be actually seen and in some cases removed, and secondly, the bronchi from which pus is coming can be determined with accuracy. When our bronchoscopists are supplied with sufficient material for constant practice they will be able to emulate our American colleagues and dispense with general anæsthesia, for in my experience the American patient is not more phlegmatic and insensitive than the British one. The more recent advance is the introduction of some substance opaque to X rays into the air passages. This has the advantage that the condition of the bronchi which are beyond the reach of the bronchoscope is rendered visible in a radiogram and the extent of the disease is determinable.

In this country lipiodol, a combination of iodine with a vegetable oil and containing 40 per cent. by weight of iodine, is the substance most frequently used. Iodism does not occur unless the oil is coughed up and swallowed as the iodine is in chemical combination and can only be set free by a process of digestion. Lipiodol is non-irritating and produces no sensation as it passes into the trachea and bronchi. There are three methods of introducing it.

Technique of Lipiodol Radiography.

1. It may be introduced through a bronchoscope by means of a syringe with a very long nozzle.

2. After anæsthetising the larynx by a spray of cocaine, a narrow rubber tube with a metal end is lowered into the trachea. The metal end is visible on the fluoroscopic screen and by altering the position of the patient can be coaxed into either of the lower bronchi. The lipiodol is then injected by means of a syringe.

3. The method I prefer is to puncture the cricothyroid membrane by a needle and inject directly into the trachea. The technique is as follows. With a hypodermic syringe filled with 1 per cent. novocaine a cutaneous wheal is made. The syringe is then filled with a 5 per cent. cocaine, the cricothyroid membrane punctured, and about 10 ℿ injected. This renders the larynx less sensitive so that drops of fluid do not provoke a spasm of coughing. A special syringe which I have devised is now filled with 20 c.cm. of lipiodol. In order that the viscosity of the oil may be reduced to the point at which it will flow readily through the needle, both the oil and the syringe should be heated. With the patient recumbent and tilted slightly to the side which is to be examined, the cricothyroid membrane is again punctured with the needle, which is 2 cm. long and, therefore, does not reach the posterior wall of the larynx. The oil is injected slowly. For an adult 20 c.cm. is a usual amount to inject. If the upper lobe is to be investigated the head and shoulders are lowered for a minute or two. The patient should take a few deep breaths as the fluid is then aspirated into the smaller bronchioles and alveoli. Lipiodol is coughed out of the bronchi if there is no obstruction within 24 hours, but if it reaches the alveoli it appears to remain for a very long time, in one of my cases for 18 months, but it apparently produces no ill-effects.

The patient should be radiographed both in the erect and recumbent position, as sometimes what appear to be single large cavities are shown by fluid levels to be composed of several smaller ones. In order to avoid iodism in a susceptible person, the patient should be instructed not to swallow any oil which may be coughed up. The needle should be sharp in order to avoid pushing the mucous membrane inward and so injecting the lipiodol between it and the thyroid cartilage. I have seen this happen, but no ill-consequences followed. By withdrawing the piston slightly air is drawn into the syringe if the point of the needle is in the lumen of the trachea.

Fig. I. is a radiogram of the chest of a girl who was bringing up much stinking sputum. An able physician was unable to detect by physical signs which was the affected lung, or even that she had bronchiectasis. An ordinary radiogram gave no help. After injection of lipiodol it was clearly demonstrated that the bronchi of the lower lobe on the left side were dilated and that the rest of the lung was normal. Fig. III. shows a different type of case in which the right lung is occupied by numerous cavities. The radiogram was taken in the erect posture and the horizontal lines show the fluid levels. The condition of the left lung is shown in Fig. IV., this time taken lying down. The second film was taken eight days after the first and the presence of lipiodol in many of the cavities in the right lung after this interval shows that drainage is not free.

Treatment.

Except in children the medical treatment of bronchiectasis is in most cases merely palliative. While under active treatment life is rendered tolerable, the amount of sputum is greatly reduced, and its fœtor is diminished. But as soon as this active treatment is intermitted too many cases quickly relapse. In the case of a working man or woman it is certain that no continuous employment is possible. There is always the risk of a cerebral abscess. Jex-Blake [1] showed that in 108 fatal cases death was due to cerebral abscess in 15. He also stated that of 30 cases due to pleurisy and pneumonia the average duration was 39 months and the maximum 144 months. Of 40 cases due to bronchitis the average duration was 110 months and the maximum 600 months. The expectation of life then is not of a high order, and in the cases with much infection that life is not a happy one. It is considerations of this kind which render surgical procedures of some severity justifiable. I should say now that before any surgical measures are taken a proper course of medical treatment should be undertaken to get the patient into the best possible condition.

External Drainage Operations.—These are only of value where one or a few bronchiectatic cavities are present. A permanent fistula results. But it must be remembered that one ounce of pus from a cavity will sometimes collect 19 more ounces on its way through the bronchi. If the one ounce is drained away externally the rest is not formed. I have seen this result follow such an operation. But the number of cases suitable for external drainage are few.

Collapsing Operation: Artificial Pneumothorax.—Collapse of the lung by this method is of great value in the early case. I feel that it should be used as a routine in cases where pneumonia is followed by fibrosis whenever the absence of pleural adhesions allows it. Fibrous tissue only contracts when it is young and after a sufficient time has been allowed for it to become adult the lung may be allowed to expand. If sputum returns the collapse should be made permanent by a thoracoplasty. In cases of old standing artificial pneumothorax is still sometimes possible. If a complete collapse is obtained and the patient is not benefited then the lesser collapse obtained by thoracoplasty is contra-indicated. If, on the other hand, the sputum disappears or is very much reduced, then a good case is made out for making the collapse permanent by rib resections.

Phrenic Exeresis.—This little operation, which is performed in a few minutes under a local anæsthesia, is sometimes usefully done as a preliminary to other measures. In itself it rarely suffices. In one case, however, in which I did it the sputum was reduced from two pints to from three to four ounces. This result was not permanent. The condition of the patient was improved, he put on 2 st. in weight, and was obviously a better surgical risk for further procedures.

Thoracoplasty.—The best results are obtained by rib resections when one lobe alone is affected. The removal of ribs must be much freer than in cases of pulmonary tuberculosis. Except in the earlier cases paravertebral resection is not enough and should be supplemented by an anterior resection as in Wilms's operation or even by complete decostalisation in several stages. There are two classes of case in which a good result may be anticipated. First, those in which preliminary artificial pneumothorax has produced a total absence of sputum or has so diminished its amount and altered its character that life is

[1] Brit. Med. Jour., May 1st, 1920.

rendered tolerable, and secondly, where there has been such a degree of contraction that the diaphragm is pulled up, the mediastinum is pulled right over, and the ribs are in the expiratory position. Such a lung has done its best to close its own cavities and if permitted, by mobilisation of the chest wall, will contract still further. The objection that the largest bronchi still remain patent is not of real weight as the drainage from them is free so that, although some mucoid secretion still has to be coughed up, infection is controlled and the fœtid sputum disappears. Instances of the value of this operation are the following.

CASE 1.—A woman of 40, who developed bronchiectasis of the lower lobe following pneumonia. Her sputum was fœtid and amounted to 3 oz. a day. While under observation for three months the physical signs extended to the upper lobe and the sputum increased. A Wilms's rib mobilisation was done and the sputum disappeared. She has been free from sputum for nearly four years and earns her living as a milliner.

CASE 2.—An officer of the Indian police, who received a wound of the lower lobe of the right lung during the war; bronchiectasis followed. I saw him seven years later when he was on the point of being invalided out of the service. At that time he was bringing up 7 oz. of stinking sputum each day. A complete pneumothorax was obtained and his sputum was at once reduced to a drachm of sweet mucus in 24 hours. The collapse was made permanent by a paravertebral thoracoplasty done in two stages, and he returned to duty and has since been promoted. He has had no sputum for three years. He was stationed at an elevation of 5000 feet and writes that he can walk 15 miles and can play three or four sets of tennis.

CASE 3 (Fig. II.).—A girl of 20, who, at the age of 4, had pneumonia. When seen she was producing two pints of the foulest sputum daily. Under medical treatment her sputum diminished to 10 oz., but remained foul. She still had severe headaches and a very furred tongue and was unable to enjoy her food properly. After a paravertebral resection her sputum diminished to 2 oz. a day and became sweet. She lost her headaches at once and her tongue became clean. The operation was only done three months ago and she may possibly improve further. As it is she is content as she now feels well and is able to live a normal life. It would have been better to have done a more complete resection, but at present she does not wish it.

As an instance of the type of case where such a limited resection is unsatisfactory I will quote the following.

CASE 4.—A man with bronchiectasis of long standing on whom I performed a phrenicotomy followed by paravertebral thoracoplasty. No benefit followed, the amount and character of the sputum being unaltered. In this case no collapse was obtained owing to the rigidity of the chest wall. A complete decostalisation might have had a better result.

I believe from my experience that the operation is attended by more risk in bronchiectasis than in pulmonary tuberculosis, at any rate in the advanced cases. Deaths from pulmonary embolus and thrombosis are certainly more frequent.

Lobectomy.—The extirpation of a grossly infected lobe must always be a hazardous operation. It is only justifiable in cases where a preliminary collapsing operation has been unsuccessful and where the patient's life is intolerable. The modern method of, where possible, bringing the lobe outside the chest wall and fixing it there, removing it two or three weeks later, appears to offer a safer method of extirpation than the older one of amputating within the uncollapsed chest. This operation has been done in France and Dr. Harrington, of the Mayo Clinic, tells me he has done it three times in America without a death. My colleague, Mr. Tudor Edwards, has also, I believe, had a successful case.

Cautery Lobectomy.—This operation, devised by Evarts Graham, is not really a lobectomy so much as a very complete drainage operation. He makes a cross section of the bronchial tree with the actual cautery and has had fair success. In his hands, however, there have been deaths from hæmorrhage and air embolism and in the hands of others the deaths from bleeding have been more numerous still. Those surgeons in America and Canada who have tried it are not satisfied that it is safer than lobectomy. In bilateral cases the surgeon can do little, but as unilateral cases form over 50 per cent. of the total there is hope for the future in the close coöperation of the physician and surgeon working together. Prophylactic treatment by artificial pneumothorax may reduce the number of cases suitable for the surgeon, but where the condition is already established I would urge that collapsing operations should be done in the early stages, when a limited resection of ribs is more likely to produce a real cure. Even where the operation is only palliative it will in the earlier cases enable the sufferer to earn his living without constant resort to courses of medical treatment followed by as constant relapses.

SIGHT-TESTING OPTICIANS AND EYE DISEASE.

BY G. P. HAWKER, B.C., M.D. CAMB.,
SURGEON TO WEST OF ENGLAND EYE INFIRMARY; OPHTHALMIC SURGEON TO WEST OF ENGLAND BLIND INSTITUTION, ETC.

AT the present time when, under the scheme of ophthalmic benefits, expert advice is available to most people who are not eligible for hospital treatment or cannot afford to see an oculist privately, it is interesting to note how frequently one comes across serious eye and general disease in patients, who have been fitted with glasses and sent away presumably without the disease being recognised. The cases cited are all from private patients—i.e., those who are in a position to pay the usual fees, and do not include any who were eligible for hospital treatment or seen there. Only one of the patients was referred for further advice and that only after a long interval, and it is therefore inferred that the conditions were not discovered. None of them had been to the jeweller-seller of spectacles, who supplies spectacles which the person chooses for himself out of the box. In two cases definite treatment had been tried, one of which was the attempted removal of a foreign body under drops for the relief of pain.

Clinical Illustrations.

CASE 1.—Woman of 30. Something in right eye three weeks ago in train. To optician in about ten days, some black shiny stuff having come out two to three days before. Some drops put in to ease pain and given some lotion to use. Went again next day and then eight days later. Been typing all time but much watering and pain like toothache. Vision: Right = 6/12 (2); left, 6/12; corrected, 6/6 and 6/5. I removed a small foreign body like a yellow husk. Some distortion from scarring was left, and both lenses showed at the periphery fluffy dots of the congenital type.

Wrong Spectacles.—CASE 2.—Woman of 52. Complains of pains back of head and giddiness. Wears cylinders of +3 spher. with 1 cyl. right eye and +2·5 spher. with 1 cyl. left. Vision: Right, 6/36, with +4·5 spher. = 6/6; left the same.

CASE 3.—Spectacles from optician. Has cylinders wrong axis. Both lenses marked vacuoles and fine dust opacities. Well-marked Fuch's colobomata.

CASE 4.—Wears bifocals from optician. Right +3 and +6; left +4·5 and +8. Vision: Right = 6/24, with −0·5 = 6/12 (2); near vision +2·25 = J4; left = less than 6/60, with +3 = 6/9 (4); near vision +7 = J1. Both lenses show considerable radial opacities.

Corneal Ulcer.—CASE 5.—Woman of 51. Worn spectacles from optician for one week. Complained of difficulty with near vision and slight cold in left eye for a week. Eye was red with sensation like grit and could not stand the light. Given two pairs of spectacles and lotion and a bottle of medicine and told to come back in a week. Left eye showed a marginal ulcer and was very injected.

Keratitis (old and recent).—CASE 6.—Woman of 27. Sight hazy some months and lids stick mornings. Spectacles for seven years; last pair 12 months ago from optician. Yesterday sudden diplopia and mistiness left eye; saw two lots of cars and two roads. Examination showed paresis

left ext. rectus and recent and old interstitial keratitis, recent only in left but old in both with tracks of vessels. History of old T.B. spine.

Absolute glaucoma; chronic, not quoted, as I am not certain of the type of optician, I think a jeweller.

Choroiditis.—CASE 8.—Man of 26. Worn spectacles six years as lithographer, first from eye infirmary, then opticians, and recently to one who could not make him see. Left eye misty six days. Vision: Right, 6/60 −4=6/4·5; left, less than 6/60 −3, with −0·75 cyl.=6/12. Right eye normal but for small crescent. Left, vitreous many fine dust opacities; below macula irregular patch of recent choroiditis of disc's size and below two other patches, one old and one fairly recent. Many dental abscesses.

CASE 9.—Man of 50. Scratched left eye with nail and shows subconjunctival ecchymosis. Recently spectacles from optician. Vision: Right, 6/18 and with +1·5=6/12. Has much perimacular choroiditis with much pigment, obviously not noticed by the optician, who did not tell him why his sight was so defective.

Cataract.—CASE 10.—Woman of 66. Worn spectacles a few months from optician, −2. Vision: Right, 1/60, and left=light only. Lids chronic blepharitis. Spectacles no use to her and should have had treatment for lids long ago.

CASE 11.—Woman of 73. Spectacles from optician a week ago. +0·75 spheres in rolled gold frames for which she was charged £2 2*s*. Vision: Right, 6/36, and with +1=6/24; left, 6/36 (1) and no improvement. Considerable posterior cortical opacities both, lids chronic blepharitis with scabs.

Diabetes.—CASE 12.—Man of 65. Spectacles three months ago from optician. Right, 6/18, with +1=6/9; left, 6/24, n.i. with spectacles. Indefinite fluffy opacities both lenses; arteries tortuous and minute small recent hæmorrhages both. Much thirst, drinks 3–4 quarts a day; referred to doctor, who found diabetes.

CASE 13.—Woman of 62. For three weeks pain above right eye with headache and nausea. After three days sight misty and things looked smoky. Daughter noticed sight of one eye—i.e., the pupil—larger than the other. Had spectacles from optician from time to time for 12 years. Examination showed right pupil dilated and fixed, lens like wet granulated sugar, and vision 6/60 n.i.; left eye 6/18, and lens showed ill-defined dots. Referred to own doctor who reported large amount of sugar.

Cyclitis.—CASE 14.—Woman of 48. Sight of left eye failing eight months, when she went to optician and was given spectacles. Bad mists getting worse. Vision: Left=fingers at 2 yards; pupil sluggish, vitreous many dust opacities, while fundus showed multiple discrete patches of choroiditis with some atrophy.

Vascular.—CASE 15.—Man of 68. Stroke five months ago, right side, partial, cleared up. Sight of right eye went suddenly July 27th; bumps into things on the right. Seen 30th, had spectacles yesterday from optician "to rest his eyes." Same morning pushed a 12-gallon milk-can about ¼ mile. Vision: Right, 6/24 (2), with +2=6/9. Fixation good. Fundi show arteries small and thread-like veins cut and full. Fields showed complete homonymous hemianopia. Here distinct danger to life was involved.

CASE 16.—Woman of 69. Recently spectacles from optician, who frightened her badly by telling her she had cataract but said nothing of the fundus. The lenses showed a few feathery peripheral streaks not affecting sight, which corrected was 6/6, but the fundi showed much Tay's choroiditis, the arteries were corkscrew and just above the left macula was an ill-defined white exudate.

CASE 17.—Woman of 77. Mists in front of eye three to four months, yellow zigzags two to three years. Last summer woke up suddenly and everything black for some hours but sight got all right though always misty. Some years ago bleeding from nose for a week. Spectacles from the opticians to a London hospital (whom, she said, ought to know all about the eyes) four to five months ago. Moderate cataract both, vitreous many coarse opacities. Vision: Right, 6/36, with head tilted back; left, 6/36, corrected 6/18. Right fundus showed senile macular changes with many old soft-edged white hæmorrhages, while the left showed a recent big hæmorrhage above the macula and many smaller of all stages.

In addition I have seen many cases, who have come to me in great distress, having been told they were suffering from cataract, of which many seemed to have great dread, only to find they had two or three streaks such as might cause no trouble for many years. Only three cases of wrong spectacles causing symptoms are quoted.

Medical Societies.

SOCIETY OF MEDICAL OFFICERS OF HEALTH.

AT a meeting of this Society held on Nov. 19th, with Dr. E. H. SNELL, the President, in the chair, Sir WALTER FLETCHER opened a discussion on

RESEARCH WORK IN PREVENTIVE MEDICINE,

from the point of view of the Medical Research Council. He referred to the work of the Council in promoting the health of the people and preventing disease, and in particular to the recent researches of Dr. Corry Mann on the diet of school-boys.[1] He said that the medical officer of health had a power of applying the fruits of research that was far greater in many respects than that of other members of the medical profession. He advocated very strongly the establishment of coöperation between the Medical Research Council and medical officers of health. The Council might be expected to promote to the utmost of its power the developments in all primary sciences in all fields which were likely to bring new weapons to the work of the medical officers. The real difficulty in getting effective application and development of research work in the field of medicine was the fact that experiments, in by far the greater number of cases, had to be done with animals, so that there must always be adaptations and adjustments. One of the difficulties of experiments on men was to arrange for proper controls. He referred to the remarkable results obtained by a certain Scottish medical officer of health in the application of the Dick test and the new preventive treatment of scarlet fever, which disease had been abolished in the nursing staffs of the hospitals in his district. So far as he knew this had not yet been tried in London; it was a benefit that had long been waiting for application. A similar "lag" was to be observed in the case of the prophylactic treatment of diphtheria by toxin-antitoxin.

Dr. W. G. SAVAGE spoke from the point of view of the M.O.H. He said that research work was the foundation of preventive medicine, the touchstone of its validity, and its only hope for the future. The medical officer of health stood as the official exponent of the application of preventive medicine.

The Field.

Far fewer mistakes would be made if facts were established on a firm basis by research before administrative measures were adopted as a general procedure for the country. Unfortunately, the validity of an attractive hypothesis could often only be tested by basing administrative action on it. The solution of this difficulty was to adopt the necessary action in sections of the country only, and to treat it as a research problem instead of booming it as an administrative acquisition. For example, the widespread installation of isolation hospitals had involved great expense to the neglect of other methods of controlling infectious diseases. Research would have demonstrated the unsoundness of the original hypothesis in the first place. If the research attitude to public health problems had been in continuous application, a wider and truer conception of the truth of many problems would have been reached much earlier. Simple goitre and acute rheumatism were problems of the moment, and the world was full of theories—many of them excellent hypotheses if regarded purely as bases for critical research. There was an immense sphere for laboratory research, but its inevitable complexity made it difficult for part-time workers. Research work in public health by no means meant laboratory work, although this was an excellent introduction and training for administrators and field workers. There was a vast deal of waste of

[1] THE LANCET, August 7th, p. 295.

research material, for instance, the piles of data elicited in connexion with school medical work and thrown into an ill-digested heap between the covers of an annual report. Rapid routine work and research deductions from the same material were almost incompatible, and chief and assistants had no time for the little bit more which would gain so much more. A sharp distinction should be drawn between data drawn from ordinary routine work and those drawn from work carried on under the especial supervision and attention implied in a research outlook. Eminent statisticians were inclined to pay too high a compliment to the value of ordinary routine figures, and were apt to base conclusions on them which clearly could not be true.

The Man and His Employers.

It was often assumed that anyone could do research work. Dr. Savage's opinion was that about 10 per cent. of average qualified men were capable of efficient research, and that investigators could not be made by training. He did not agree that every officer in the public health service should undertake research work. Rather should suitable individuals be selected, their facilities enlarged, and their efforts seconded. To find and to utilise workers in the field of preventive medicine was one of the paramount needs of public health.

Of the several factors which united to make the harvest so scanty the chief was the lack of time. Local authorities who appointed and controlled officers in the public health service had but the dimmest idea of the importance of research work, and with but rare exceptions contributed nothing to it but severe discouragement of any expenditure on equipment or additional personnel. Nor did central health and educational authorities give much help in the stimulation of local bodies. Moreover, there was a lack of willingness among the officers themselves to devote their leisure time to research, and great credit was due to those who persisted in the face of much passive discouragement.

Criticisms of the Present System.

Prof. W. W. C. TOPLEY said that the greatest triumphs of bacteriology had been in the field of preventive rather than of curative medicine, and that the medical officer of health was in a quite exceptionally favourable position for taking the wide biological view of problems.

If research was to play its proper part in the service it must be given reasonable help and encouragement, at present conspicuous by their absence. A broad distinction should be drawn between routine examinations and investigations leading to an advance in knowledge. If men of active and inquiring minds were to be attracted to the laboratory side of public health work they must not be condemned to too much routine work. A young post-graduate should feel that a laboratory post with facilities for research was one of the alternatives to look forward to if he entered the public health service. The R.A.M.C. had provided an instance of the benefits which accrued to a service from the presence of an able and original laboratory investigator. If the bacteriological laboratory were made an integral part of the public health service there would also be a considerable drift from the laboratory to the administrative side and back again, to the great good of the service as a whole. A man who had learned what a laboratory could and could not do was clearly at a great advantage when he came to investigate infective disease in the field. The present system, whereby most of the public health laboratory work was done in university departments, endowed institutions, or commercial laboratories, was unhealthy for all concerned. The work was well and economically done, and the institution gained financially, but so long as they undertook such work it must be a first charge on their energies, whereas the primary duty of universities and research institutes should be the training of students and the advancement of knowledge without regard to its immediate application. A man could not serve two masters. The research work of such institutions did not in any way arise out of the routine examinations, and must be developed along its own lines and not governed by the relative urgency of particular problems in applied bacteriology.

The Remedy.

The position which might well develop if local authorities took over their own bacteriological work would be worse than the present one. It was essential to see that each institute combined original research with routine investigation. For this the unit must be large. The small laboratory was very expensive and relatively inefficient. For example, the cost per test of the Wassermann reaction would be five times greater in a small laboratory than in a large one. Performance of a large number of tests daily was a valuable safeguard against faulty reagents or other sources of error. Moreover, in a large laboratory the staff could enjoy considerable elasticity of work, which would enable them to undertake research. This would be still better provided for if several laboratories could be so linked as to facilitate interchange of staff and the concentration of special departments of work in different institutions. The work of such laboratories must be confined rigidly to those examinations which were concerned with the ordinary routine of public health work, as distinguished from that usually called clinical pathology. The areas to be served by such laboratories could not be determined by the present administrative boundaries. The danger of cramping research work and producing a less efficient and more expensive service by some attempt on the part of local authorities to set up each their own little laboratory was real and urgent, and some society such as this should put forward a considered policy.

The Statistical Method used by the Amateur.

Dr. MAJOR GREENWOOD defined research as the bringing to light of the relation between phenomena or facts, which might either have been long known or first brought to light by the investigators; if the relations deduced led to some practical rule which might cause saving of life or reduction of pain or sorrow, then that research had value for the public health service. Very few medical statisticians had been in a position to modify facts. In the enormous catalogue of ascertained facts that we now had there were important relations to be deduced between certain of them which had never been noticed, but it was much harder to find them than it was before the eminent Victorian statisticians had done their work. The modern seeker, however, had the advantage that the field had been very much enlarged since then. Several countries now had medical statistics as good as our own, and if the medical officer had to ration his time between learning statistical methods and making himself familiar with the statistics of other countries, he should devote the greater part of his time to the latter. The speaker would not make algebra a compulsory subject for the D.P.H. but he would make the ability to read French and German fluently an absolute qualification. Facts should be taken first-hand and not from other men's books. He referred to the Medical Research Council's recent reports on Diet for School-boys and the Evolution of an Epidemic of Diphtheria in a Boarding-school, and pointed out how each depended on continuous observation of a closed community in which the changes in composition could be exactly known and studied. The value of boarding-schools for research had been underrated; no school had yet found its Gilbert White, ready to study what was happening all the time. Much light might be thrown on the evolution of respiratory epidemics, and on what happened before an outbreak of such diseases as scarlet fever and poliomyelitis. The disadvantage of mice as the subjects of experiment was that we could not speak their language and all cases were necessarily fatal.

The departmental committee of the Ministry of Health on cancer had recently set itself the question: How many people are radically operated on for cancer

of the breast and how much longer do they live than people who are not, and if the proportion is small, why is it small? This needed the coöperation of medical officers of health, and required that all sanitarians should think the problem out and consider how it might be studied. It was a striking feature of the work of the greatest living master of statistical method—Prof. Karl Pearson—that scarcely any of the efforts of the public services had been praised by him. Destruction must precede construction, but there was a danger of supposing that "Not proven" and "Not guilty" were identical verdicts, and of regarding the medical statistician as a superior person picking holes in other people's work.

Discussion.

Dr. J. T. C. NASH said that in his district of Norfolk there were very few isolation hospitals, and not 10 per cent. of the infectious cases were isolated. It was, however, very sparsely populated. There was a scheme of notification by school-teachers of all cases of absence due to infectious disease. Copies of these notifications were sent to district medical officers, and all agreed that much more information was gained thereby than by the more usual methods. The figures of the district compared very favourably with those of an adjoining area where there were eight hospitals and 80–90 per cent. of cases were isolated. Last year there had been 550 notifications of scarlet fever and no deaths. He was against small units; an isolation hospital was only of use if it were large, well staffed, and well looked after. He would add to the qualifications of the D.P.H. a good knowledge of logic.

Dr. ANDREW BALFOUR pointed out that it had been said that in no single case had the organism of a communicable disease been discovered by any medical officer of health in this country. This had not been to any great extent the fault of the officers, but he was concerned with any measures of improvement that might be effected by the new School of Hygiene and Tropical Medicine. It could not be expected to create research workers, but it might be able to find out who were the men who had received the divine touch and guide them and suggest to them fruitful lines of research. It must also educate the local authorities, which was no easy task. They must be shown graphically that it would pay them handsomely to allow their officers some time off to see what was going on. This might be done by the proposed great Museum of Hygiene; invitations might be sent to all laymen connected with public health to come up to demonstrations of how research had helped to combat disease. The School should also provide refresher courses in research work and a training in scientific French and German, and, if necessary, other languages. All medical research should tend towards the preventive idea.

Dr. A. B. MCMASTER asked what would be a suitable unit of size for an effective pathological laboratory. He pointed out that medical officers had done much research into communicable disease, but naturally their work had not gone, and should not go along the lines of laboratory research. He instanced the pioneer work of Niven on the spread of tuberculosis.

Dr. E. WARD said that the chief difficulty of research among private practitioners and the accessory public health services was that of finding people who could do research work. So many seemed to think that enthusiasm was the only quality necessary. Most of all should they beware of research by questionnaire, which seemed to substitute for the obiter dicta of great men the opinions of small men, and led to no great advance. It had been said that research was hampered for lack of advice, but the man who depended on his research for his initiative was not likely to achieve more than mediocrity.

Dr. W. JAMESON pleaded for clinical research, especially into the problem of small-pox and alastrim. It appeared that it was possible at the end of the third week of an epidemic to state definitely whether it was the kind of "small-pox" that was going to kill people or not. What was happening was that in the provinces large numbers of people were coming to regard small-pox as a trivial disease, less troublesome than vaccination while in London it had really been a horrible thing. The "country" type only killed those at the extremes of age or those suffering from some other disease. Of four deaths in Gloucester recorded as due to small-pox, one was an infant, another was a baby with severe diarrhœa, the third was a child with malignant measles and the fourth was an old gentleman.

Dr. R. MAULE HORNE brought forward the point of view of public opinion, which sometimes took a great deal of inducement to recognise research and was apt to ask "what the man meant by poisoning innocent children."

The PRESIDENT said he could not agree that research workers could not be made. It was quite possible for a comparatively ignorant worker to make a discovery he was not even looking for. A vast responsibility rested on the Medical Research Council to direct work in fruitful directions. Many medical officers of health were doing unorganised work.

Reply.

Sir WALTER FLETCHER, in reply, said that the value of research was rising, and would rise more in public opinion. The great difficulty now was the want of sympathy of lay authorities, a difficulty that seemed to be less if a woman was in charge. Medical officers of health could do more than anyone else to help in educating public opinion, and should seize every opportunity.

Dr. SAVAGE, in reply, agreed about the complete worthlessness of questionnaires and small laboratories, but still maintained that research workers were born, not made. An accidental discovery was not necessarily research.

Prof. TOPLEY, in reply, said that the effective laboratory unit would roughly be one that cost between £10,000 and £20,000 to build, between £5000 and £8000 a year to run, that tested 20,000 to 30,000 specimens a year, and served a population of 400,000 or 500,000.

Dr. GREENWOOD, in reply, said that statistical research was the only kind that the ordinary assistant medical officer of health had a chance of doing, and pleaded that their seniors should encourage them in it and advise them to seek the help of the Medical Research Council.

MEDICAL SOCIETY OF LONDON.

DIAGNOSIS AND TREATMENT OF BRONCHIECTASIS.

AT the Medical Society on Nov. 22nd, Sir HUMPHRY ROLLESTON presiding, a discussion took place on recent advances in the diagnosis and treatment of bronchiectasis. The openers were Dr. CLIVE RIVIERE and Mr. J. E. H. ROBERTS, whose papers appear at pp. 1102 and 1106 respectively.

Discussion.

Two foreign visitors, in response to the President's invitation, said a few words. Dr. ARMAND DELILLE suggested the possibility of limited bilateral rib resection as a procedure of some promise, and Dr. SCHRÖDER, who said that he had not seen very good results from thoracoplasty, favoured a more extensive rib resection than had been advocated by Mr. Roberts.

Dr. L. S. BURRELL emphasised the value of medical treatment, pointing out that if one could get the patient sufficiently early medical treatment would keep him alive and well without surgical interference for the rest of his life. Before starting any treatment whatever, the cause must be carefully looked for, and foreign body, aneurysm, syphilis, or neoplasm excluded. The two courses of treatment that he advocated were posture and some form of creosote therapy. With regard to the more serious forms of treatment, if the patient did not improve, and there was definite evidence of localised trouble, one should try either artificial pneumothorax or washing out the tubes through the bronchoscope. When a satisfactory collapse was obtained, treatment by artificial

pneumothorax was very successful, but the trouble tended to recur when the treatment was stopped. He had seen very good results from washing out with the bronchoscope, and in skilled hands this procedure was certainly not painful nor very inconvenient. With regard to surgical treatment, in his opinion thoracoplasty was not satisfactory in these cases. His own preference was for pneumectomy with the cautery—Graham's operation. Lobectomy with the knife was so dangerous that one could hardly conceive it being justifiable. But he held that no surgical treatment should be attempted until the possibilities of medical treatment had been fully explored.

Mr. TUDOR EDWARDS said that the value of lipiodol in the diagnosis of bronchiectasis was definitely established. It was specially valuable when the question of surgical treatment arose, because it was essential for success that the disease should be unilateral, or at any rate that the extension to the better side should be known and the amount roughly estimated. Artificial pneumothorax would not cure established cases of bronchiectasis, and in those cases in which it diminished the sputum temporarily thoracoplasty would make that improvement permanent. In early cases artificial pneumothorax might allow for sufficient contraction of the fibrous tissue to prevent the extension of the disease, but as soon as the lung was allowed to expand this process would extend. He had performed phrenic evulsion on patients with bronchiectasis 20 times, and in almost every case there had been some improvement, either in diminution of sputum or amelioration of symptoms. In one or two cases evulsion had led to cessation of severe hæmoptysis in bronchiectatic cases; unfortunately, in a proportion of cases the amelioration was not maintained. The results of thoracoplasty were somewhat variable. He had performed this operation on 11 patients with bronchiectasis. In four of these the results had been excellent, three had no sputum nor symptoms, the sputum in the other case had diminished from 10 oz. (offensive) to 1 oz. (non-odorous) per day. The other cases gave less satisfactory or definite results. He had performed Graham's operation of cautery pneumectomy in one case, but the result had not been satisfactory.

Dr. F. G. CHANDLER said that he did not know whether lipiodol would give a characteristic picture in the really early stages of the condition, but he was quite convinced that it would prove dilatation at a stage when the symptoms were only slight and the general condition good. The diagnosis having been made and the condition having proved unilateral, decision was by no means easy. To advise a major operation, which was attended with risk, and from which definite results could not be absolutely promised, was no light responsibility. Postural treatment, creosote chamber treatment, and prolonged climatic treatment all helped, but it was doubtful if they would cure. Vaccines, he believed, from a recent experience, were not without risk. He thought the best course was to do a pneumothorax, keeping the lung collapsed for one year and then allowing it to expand. This might prevent an extension of the disease, and there was some evidence available that it might cure, but time alone would show whether this was so or not.

Dr. LENNOX WAINWRIGHT mentioned that he had a case many years ago which looked like dying. He was advised to inject ichthyol (5 per cent. in glycerine). The patient coughed up very violently and gradually improved; he was now 82 years of age.

Sir PERCIVAL HARTLEY thought that bronchiectasis was altering a little in character; it was not so offensive as formerly, and in view of these better conditions and prognosis it was specially needful that care be taken before advising serious surgical operations. Preventive treatment was essential after whooping-cough and broncho-pneumonia. Phrenic evulsion was a harmless method which could be used in a good many cases. Artificial pneumothorax did not often lead to permanent improvement. A certain number of thoracoplasties did well.

Dr. GEOFFREY MARSHALL pointed out the importance not only of posture but of exercises, and described a system of exercises worked out in the massage department at Guy's.

Mr. ZACHARY COPE asked whether anyone believed that creosote had any killing effect on microbes in the lung; it seemed to him more a matter of faith than of creosote.

Sir JOHN BROADBENT thought that the cases which occurred after pneumonia, whooping-cough, and the like were much more likely to have infected cavities and to give rise to offensive sputum than those which followed simply from pressure on the bronchus.

Reply.

Dr. RIVIERE said that the impracticability of patients who had to do their ordinary work resorting daily to the creosote chamber had been pointed out, but this was not necessary; after a time they might leave the creosote chamber safely if they carried on drainage or use it only at quite longish intervals.

Mr. ROBERTS said he regarded extensive operations in these cases in the light of an amputation—a confession of failure. But his point was that where medical treatment had failed the surgeon should be asked to come in at a stage when a simple operation would offer the patient a chance to lead his ordinary life.

BRISTOL MEDICO-CHIRURGICAL SOCIETY.

AT a meeting of this Society held on Nov. 10th Dr. A. L. FLEMMING, the President, took the chair, and Mr. A. W. ADAMS read a paper on the

Treatment of Congenital Club-foot.

He spoke particularly of congenital talipes equinovarus as being the commonest variety. The ætiology was unknown, he said, but he inclined to the old theory put forward by Hippocrates and by Galen, that deficiency of the liquor amnii allowed pressure on the fœtus. The theory of arrest of development could not account, he thought, for some of the varieties. The incidence was greater among males and it was said to show a familial tendency, but this was found in two cases only of his own series, the patients being brothers. There was a tendency to associated deformities, and the condition often affected both feet; in Mr. Adams's series both feet were affected in half the cases. Discussing the usual deformity, he pointed out that two factors must be recognised—rotation inwards on an antero-posterior axis brought the os calcis up under the internal malleolus; rotation inwards on a vertical axis at the midtarsal joint brought the fore part of the foot pointing inwards, and the sole backwards. The tendons and ligaments on the inner side of the ankle-joint were shortened.

For a successful cure, said Mr. Adams, two things were essential: (1) early treatment, beginning at the age of one month if possible, when the tissues were pliable and the bones relatively plastic; and (2) regular, prolonged, and continuous treatment. It was a waste of time to attempt treatment on manipulative lines unless the parents realised that for success they must coöperate with the surgeon. For several weeks treatment aimed at reposition; for some months at retention; and for some years at education. The first step was to secure the reposition of the astragalus; this was brought about by manipulation around the antero-posterior axis. The astragalus was forced in under the tibia, and the os calcis was drawn downwards and outwards under the astragalus. In addition to forced movements by the surgeon the foot was moved as far as possible into the correct position several times a day by the nurse, being held there for a few minutes. When the posterior part of the foot was rotated, the anterior part was turned outwards on a vertical axis. Slight over-correction was the aim. In all cases some fibres

of the deltoid ligament had to be divided, in many cases part of the inferior calcaneo-scaphoid ligament must be severed, and in a few tenotomy was needed. As soon as the foot could be brought well out it was put up in plaster for several weeks, with changes and manipulation once a fortnight. The tendency for the plaster to fall off a fat leg and foot was met by carrying it up over the knee, or by incorporating strapping. The next step consisted in tenotomy of the tendo Achillis, without which attempts to correct equinus would stretch the plantar ligaments. The over-correction should not be too great. A wooden sole-plate was used with strapping to retain the foot in the over-corrected position. Movements and massage were continued at regular intervals, and this was the difficult time, for parents saw the foot in a good position and wished to discontinue attendances that had become wearisome. At 18 months a malleable splint down the back of the leg and along the sole was employed, fitted with a toe-plate to resist the tendency to varus. The child was encouraged to walk, but wore the splints day and night; a small overshoe was used with the splint. The régime of massage and movements was continued long after the splint could be discarded, and by the age of 3 the child could learn simple exercises and so coöperate in treatment. In some cases, however, iron supports were needed for several years, and in others—those which came late for treatment—cuneiform osteotomy was required. The only absolute bar to cure was failure to attend the surgeon regularly for the necessary period of several years. This might be interrupted by a variety of causes—illness in the family, a new baby, poverty, or, most exasperating of all, stupidity or carelessness of parents—any of these might vitiate the results of months of work. Long treatment in plaster seemed to interfere somewhat with the nutrition of the limb. Neither this nor some degree of flat-foot, which was not uncommon, appeared to cause the patients any trouble. There was a tendency to hallux varus when the child began to walk without splints, and in some cases an inward twisting of the tibia; osteotomy of the tibia might be needed, but had not been employed in any of the cases shown. In conclusion, Mr. Adams described the results obtained with 33 feet, to show how regularly results less than "good" were associated with sporadic attendance. Eight cases were shown to illustrate the later stages of treatment, and many photographs to demonstrate the application of various forms of retention apparatus.

Prof. E. HEY GROVES agreed that the greatest difficulty in treatment was to secure the efficient coöperation of parents. He thought that sufficient emphasis had not been given to the correction of the malposition of the astragalus; he had found that reposition in a small flat-foot was not easy, but thought that failures were often due to this part of the deformity not having been corrected. He advised osteotomy of the tibia where the foot looked inwards. Tarsectomy gave excellent immediate results as regards reposition, but the after-treatment needed to be just as careful and prolonged, and the final result was not so good, as with manipulative methods. He particularly admired the sole-piece used by Mr. Adams.

Mr. H. E. CHITTY agreed that the displacement of the os calcis was the most difficult part of the deformity to reduce. He found plaster splints very difficult to retain in position, and used a small internal malleable splint. In late cases he took out a wedge on the outer side to correct the heel, and found the remaining correction easy.

Mr. E. WATSON-WILLIAMS noticed that the first case shown, and several of the photographs, had the second or third toe pushed up out of line so as to lie on the dorsum of their neighbours. He asked whether this disappeared of itself later, what was required to correct it if not, and whether it was connected with the tendency to hallux adductus.

Mr. W. A. JACKMAN said that he regularly used Mr. Adams's splints. He had had very good results in seven cases out of eight with splints, not using plaster. All his patients had bilateral deformity.

The PRESIDENT asked whether the almoner's department had been used to follow up the cases and added that the wealthy failed to get the best treatment, as well as the very poor, for they were inclined to go from one surgeon to another, and thus lost the benefit of continuous treatment by one method. This type of deformity, he believed, was related to defective heredity, which was relatively common in remote and isolated districts.

Mr. ADAMS, in reply, said that he recognised that the posterior deformity was the most difficult to treat. The correction could be made at the same time as the abduction, and it was not difficult to overdo it. As to the advantage of plaster over splints at the early stage, he thought that splints needed daily attendance. The following of cases, he agreed, would be easier if there were an officer specially detailed for this service, and great efforts were often needed to keep some parents attending regularly.

Mr. E. R. CHAMBERS showed a case of carcinoma of the uveal tract in a woman of 55 of four months' duration. An exactly similar growth had been removed from the same site five years ago. He proposed to treat the condition with radium.

Dr. A. D. FRASER showed eight specimens of endometrioma, and briefly described them.

JAMES MACKENZIE INSTITUTE FOR CLINICAL RESEARCH.

ON Oct. 26th Prof. SHAW DUNN read a paper on

Disturbance of Renal Function in Experimental Nephritis.

Referring to the object and scope of his research into experimental nephritis in animals, he pointed out the difference between the acute form as seen in the rabbit and in the human subject, and showed the essential lesion in the former to be in the first convoluted tubule, and not in the glomerulus. He made the interesting observation in this connexion, however, that albuminuria did occur, and hence it might be presumed that some functional change took place in the glomerulus also. Describing the results of inducing nephritis in rabbits by giving sufficient doses of oxalates, he showed that there was a diminution in urinary nitrogen excretion and an increase in the blood-urea, sometimes to high levels. There was also, he stated, acidosis, and it was probable that an additional function of the renal tubule was the maintenance of the body's alkaline reserve. The diminution in the percentage of urea excreted and the rise in blood-urea showed a diminished power of concentration by the kidney. By the injection of saline, however, an artificial polyuria might be produced which washed out the urea in large quantities and brought down the level of the blood-urea. Prof. Dunn put forward the view that the retention of urea might be explained by the hitherto impermeable tubule cells being killed or damaged, and hence becoming permeable and permitting the reabsorption of urea. So, also, anuria might develop. The few experiments which had been possible on chronic tubular lesions confirmed the main conclusions and showed the importance of an adequate supply of water to secure a sufficient excretion of urea, and the danger of reducing this supply in cases in which the concentrating power of the kidney was permanently lowered.

On Nov. 3rd Dr. BARCLAY NESS read a paper on Difficulties in the Clinical Diagnosis and Prognosis in the various forms of Chronic Bright's Disease.

THE "PENNY IN THE POUND" AT RUGBY.—The board of management of the St. Cross Hospital, Rugby, is instituting a "penny in the pound" scheme to replace the existing "flat rate" which limited the number of cases admitted in proportion to the amount paid by each firm.

Reviews and Notices of Books.

THE HEART.

By ALEXANDER GEORGE GIBSON, D.M., F.R.C.P. Lond., Physician to the Radcliffe Infirmary. London: Humphrey Milford. Oxford Medical Handbooks. 1926. Pp. 108. 5*s*.

A BRIEF exposition of cardiology may be technical or it may be popular, but it can hardly be both. To compress even the most fundamental facts and theories of cardiology into 100 small pages is an impossible task, but it is surprising how much information this little book does contain.

A first chapter on general principles is followed by an admirable short account of the aims and methods of clinical examination, in which the author deals briefly with the recognition and significance of over-action of the heart, valvular lesions, cardiac enlargement, variations in rhythm, ætiology, and efficiency tests. Another useful chapter on the recognition of the normal heart and one on instrumental methods are followed by 30 pages devoted to diseases and disorders of the heart. This section is extremely condensed and the drawings illustrating the various lesions are not worthy of the space devoted to them. The two final chapters deal with the principles of prognosis and treatment, and are followed by a good bibliography. The views expressed by the author are for the most part in accordance with modern teaching. There are, however, certain statements with which many cardiologists will disagree. For example (p. 37), that the diastolic pressure corresponds to the loudest sounds; (p. 57) that subacute bacterial endocarditis is invariably fatal; (p. 70) that complete heart-block gives rise to the Stokes-Adams's syndrome; and (p. 95) that digitalis should not be given to patients with heart-block. Some of these views are perhaps open to differences of opinion; but the statements on p. 6, which imply that cyanosis is due to an increased tension of carbon dioxide in the blood, and that the condition of oxygen-want is seldom seen at the bedside, do not accord with facts now well established.

We doubt whether Dr. Gibson is right in believing that the subject of cardiovascular disease has yet attained a sufficient degree of exactness and finality to enable it to be treated on simple lines, but, at any rate, his book can justly claim to give a bird's-eye view of the present-day conception of the subject.

AGRAPHIA.

Über die Agraphie und ihre lokaldiagnostischen Beziehungen. By Dr. GEORG HERRMANN and Prof. Dr. OTTO PÖTZL. Berlin: S. Karger. 1926. With 29 illustrations. Pp. 380. M.24.

THE study of aphasia is in danger of becoming more than ever complicated by reason of the number and size of the contributions which it appears to invite. When a volume of nearly 400 pages is devoted to agraphia alone the wonder arises that its authors should not be content with supplying in more concise form the results of their researches; life is short, but the subject of aphasia seems unconscionably long.

The authors rely mainly on their case of tumour of the right parieto-occipital region in an ambidexter. Agraphia was the prominent symptom throughout, but some alexia, left homonymous hemianopia, some motor and sensory paresis of the left side, and innervation-apraxia of the fingers of both hands were also present. They distinguish this "parietal agraphia and alexia" as a definite clinical type, attributable to lesions involving the supramarginal gyrus and its immediate vicinity. They conclude that writing is bilaterally represented in the cortex, sharing this bilaterality with other components of speech but not with all. Some attention is given to agraphia of frontal origin, and to the occurrence of agraphia with other aphasic symptoms in lesions of temporoparietal site. It is rather by the accompaniments of agraphia in a syndrome than by that symptom alone that distinctions can be drawn between the varieties resulting from lesions in the three above-mentioned areas.

Included in the volume is an examination of a large number of recorded cases of agraphia, and sections are devoted to discussion of the relation of agraphia to apraxia, to micro- and macrographia, to so-called paligraphia, and "Lautagraphie." The conceptions of Bastian, Pick, von Monakow, Wernicke, Henschen, and Mingazzini in regard to agraphia receive attention. Thus it may be said the monograph is comprehensive in a noteworthy degree, but it is rather unwieldy and somewhat wordy, and its value would not have been impaired by greater succinctness and by more frequent summaries of the argument.

TOXICOLOGY.

Fifteenth edition. By ALBERT H. BRUNDAGE, A.M., M.D., Phar.D., M.S., Consulting Toxicologist to the Bushwick Hospital, New York. London: D. Appleton and Company. 1926. Pp. 444. 18*s*.

THERE can be no doubt that the author of a book which has reached its fifteenth edition has been able to provide his readers with reliable information. Once a reputation is established, however, there may be loss of efficiency unless each edition is subjected to critical revision and any necessary additions carefully incorporated. Unfortunately, in this fifteenth edition of Dr. Brundage's work, the sequence of the argument is allowed to suffer. In many instances the page reference to a subject in the index does not direct the reader to the right place in the text. Eight times the continuity of the page numbers is broken to introduce *a*, *b*, and *c*, &c., pages; a most inconvenient arrangement and probably responsible for the inaccuracy of the index. The symptoms and treatment of aspirin and luminal on pp. 60*e* and *f* are out of place and should have appeared in part two which deals with poisons alphabetically, and commences on p. 61. Toxicology has been defined as the science of poisons, and accepting this definition even in its broadest sense, it is difficult to understand the inclusion of a complete scheme of infant feeding occupying 22 pages. The author's apologia for the inclusion of the infant feeding section appears to be the possibility of a poisoned mother being unable to feed her child naturally, but this might well have been omitted and more space allotted to the important section of toxicology dealing with the post-mortem findings which is only allowed 20 pages. A number of sections in Dr. Brundage's work are very valuable. Of these the classification of symptoms which various poisons may produce and the tabulation of substances causing change of colour in urine and fæces may be cited as examples. A most useful inclusion is that of a full glossary of the composition of patent medicines. There is no doubt that Dr. Brundage's book will continue to prove of great value to those who are suddenly called to diagnose and treat a case of poisoning.

Lead Poisoning. (Medicine Monographs, Vol. VII.) By JOSEPH C. AUB and Others. From the Department of Physiology, Harvard School of Public Health, and the Medical Clinic, Massachusetts General Hospital. London: Baillière, Tindall and Cox. 1926. Pp. 265. 18*s*.

THE issue of this volume, the seventh of the series, was rendered possible by the Harvard Medical School, from funds placed at their disposal by the National Lead Institute. They were fortunate in obtaining the services of Dr. Aub and his collaborators, for their work is a notable contribution to medical science. It would be interesting to learn what is the constitution and what are the functions of the National Lead Institute. Are its members drawn from those engaged in the commercial production of lead and its compounds as well as from the scientific professions, including medicine? An institution with such a

combination of members would be of real value to the community, for conflicting interests might be freely discussed within their walls. In any case an organisation which gives facilities for the production of works such as Dr. Aub's places us in its debt.

The volume is divided into four parts, chemical, pathological, physiological, and clinical. In the chemical section the solubility of lead and its compounds in the body fluids is stressed. A good case is made out for the circulation and deposition in the tissues of lead combined with the phosphate radicle, and experimental work quoted shows that such an event is likely under the hydrogen-ion concentration normally found in blood and tissues. Analyses of organs of those who are well known to have ingested lead show that not only is the majority of lead found in the bones, but that it may be found in this situation when its detection has failed elsewhere. The pathological section attempts to correlate the clinical and pathological states and a full classification of lesions which may be found is given. In the physiological section the effect of lead on the blood cells is described in detail and the chief signs and symptoms of plumbism are discussed on a physiological basis. The experimental work here described on normal erythrocytes and artificially "leaded" cells is noteworthy. The clinical section pays special attention to the difficult problem of the early diagnosis of chronic plumbism. Administration of phosphoric acid and the limitation, as far as possible, of calcium in the diet have proved the most valuable "deleading" measure in the hands of Dr. Aub and his colleagues; they bring forward experimental work which suggests a similarity between calcium and lead metabolism.

There are two important effects of lead which receive but cursory mention—sterility and abortion. It is true that an attempt is made to explain the latter, but the much discussed question of the affinity of lead for embryonic and rapidly growing tissues, and the findings of excessive quantities of lead in the placenta of those suffering from lead poisoning are worthy of a more complete study than is here devoted to them. One sentence in this book (p. 239) should be pondered by all those concerned with industrial health. The author states: "In almost all cases of industrial plumbism and in all serious cases, it will be found that the workman has been poisoned by lead which entered his body with the inspired air."

BIOLOGY.

Biological Monographs and Manuals. No. VI. The Anatomy, Histology, and Development of the Pituitary Body. By G. R. DE BEER, M.A., B.Sc., F.L.S., Fellow of Merton College, and Jenkinson Memorial Lecturer in Comparative and Experimental Embryology in the University of Oxford. London and Edinburgh: Oliver and Boyd. 1926. Pp. 118. 12*s.* 6*d.*

AN excellent little book. As may be inferred from the title, the work is not concerned with considerations of the physiological functions of the pituitary body, but with its morphology, and contains short and clear accounts of its structure, development, and histology in the various divisions of the vertebrates. The author works through his subject from the mammals down to the Cyclostomes. We turned with great interest to his account of the conditions in Selachians, for it has been held that the organ in this group does not answer the physiological tests which are positive among other Craniata. We have no indication of Dr. de Beer's views on this particular matter, but he gives an account of the structure of the gland in these fishes which seems to put it definitely in line with the others, a fact which one would anticipate from its development. Attention might be called, however, to his statement (p. 68) of the existence of certain curious large cells in the ventral lobe, about 20 or 30 feet in diameter; a printer's error must be held responsible for this overstatement. The author brings out well the interesting and important connexion of the hypophysial pouch with the premandibular somites in some lower forms, and the consequent existence in them of representatives of "proboscis pores," although no doubt some will probably not see eye to eye with him in his deductions from the occurrences. The little work is one which every comparative anatomist and embryologist should have for handy reference. In addition to its excellent illustrations, it is completed by a bibliography which gives all the writers on the subject since the publication of Stendell's exhaustive list in 1914.

The Memory Factor in Biology. By C. J. PATTEN, M.A., M.D., Sc.D. London: Baillière, Tindall and Cox. 1926. Pp. 175. 5*s.*

THE professor of anatomy in the University of Sheffield adds a lively interest in nature, and especially in birds, to his other occupations, and he has put together out of a number of popular addresses a statement of the psychical side of his biology. Any form of dualism he entirely rejects, and he presents an elementary summary of the conception that the world is a unitary whole and that in memory of one kind and another we should recognise the immaterial part of our being. Students of Samuel Butler and his "unconscious memory" will be familiar with much that Prof. Patten has to say; his book is an edifying antidote to the dissecting room and will be of value if it stimulates its readers to dig deeper into the literature of the subject.

MANUAL OF SURGERY.

Vol. III. Seventh edition. By the late ALEXIS THOMSON, M.D., F.R.C.S. Ed. and Eng., and ALEXANDER MILES, M.D., LL.D., F.R.C.S. Ed. London: Oxford University Press. 1926. Pp. 567. 12*s.* 6*d.*

THIS third volume completes the new edition of the Manual of Surgery and, including as it does the whole of the surgery of the chest and abdomen, it forms the most interesting volume of the series. It has been brought well up to date and contains a vast amount of information; the clear arrangement which has been adopted makes access to any particular subject an easy matter. It is profusely illustrated both by photographs of actual cases and diagrams. The former illustrate for the most part rare and extreme conditions and will, perhaps, appeal more to the experienced surgeon. The diagrams are well chosen and should be of great assistance to the student in enabling him to understand the pathology of such complicated conditions as rectal fistulæ and pancreatic cysts. The volume fully maintains the standard of its predecessors.

ANATOMIE DES MEMBRES.

Second edition. By Ch. DUJARIER, Chirurgien de l'Hôpital Boucicaut. Paris: Masson et Cie. Pp. 422. Fr.45.

THIS edition is practically a reprint of the first, which has proved a success among the students for whom it was originally written. The book is of the nature of a dissecting manual, if such a name can be given to one of this size, and deals with its subject from the point of view of the dissector. It is interesting to note in this connexion that the author does not hesitate to introduce so-called "abnormalities" in his illustrations, his object being to show conditions as they may be met with in the dissecting room, rather than to confine himself to an account of the accepted type as if it were unalterable. The directions for dissection, although probably sufficient, do not err on the side of excess, but the descriptions of the regions are good, full, and clear. The illustrations are also to be commended, and in many cases show the influence of Farabeuf, some of whose actual figures are also introduced. Farabeuf, whose style of drawing was in some respects apparently derived from Vesalius, although, of course, with immense improvement, was the author's teacher in anatomy, and the book is dedicated to him.

COMPARATIVE ANATOMY OF VERTEBRATES.

Third edition. By J. S. KINGSLEY, Emeritus Professor of Zoology in the University of Illinois. Philadelphia: P. Blakiston's Sons and Co. 1926. Pp. 470.

NINE years have elapsed since the last edition of this work appeared, so that we welcome this issue. The book has increased in size considerably, and many new figures have found their way into it, but it still retains those characteristics which have made it such a favourite in the past. Prof. Kingsley is an authority on the subject on which he has written, and has produced a text-book which will be the standard one in the English tongue for many years to come. The book is beautifully produced and admirably illustrated.

Reports and Analytical Records.

CRUSTLESS CHEDDAR AND CHESHIRE CHEESES.

(WILTS UNITED DAIRIES, LTD., TROWBRIDGE, WILTS.)

THESE cheeses are stated to be made from full cream milk. Packet cheeses are imported which are described as of Cheddar flavour, whereas the products of the Wilts United Dairies claim to be actually Cheddar and Cheshire cheeses. The method of packing each of the six sections in a box in "silver paper" prevents contamination. Both cheeses possessed an agreeable and pleasant flavour characteristic of their types. On analysis the following results were obtained:—

	Cheddar.	Cheshire.
Weight of each section	35·6 grammes.	37·4 grammes.
Moisture	44·1 per cent.	43·5 per cent.
Total ash	3·06 ,,	3·24 ,,
containing salt (NaCl)	1·17 ,,	1·23 ,,
Protein	22·06 ,,	22·06 ,,
Fat	27·84 ,,	27·00 ,,
Lactic acid	1·40 ,,	1·40 ,,
Undetermined	1·54 ,,	2·80 ,,
Calorie value per lb.	1586	1551
Preservatives	Absent.	Absent.

The absence of sugar is of some significance for diabetic patients.

"TABLOID" DIGITALIS LEAF (GR. ½).

(BURROUGHS WELLCOME AND CO., SNOW HILL BUILDINGS, LONDON, E.C.)

In THE LANCET, Oct. 24th, 1925, we called attention to "Tabloid" Digitalis Leaf (gr. 1). This has proved such a satisfactory and efficient means of administering the drug, that Messrs. Burroughs Wellcome and Co., in order to meet the demands of medical practitioners who wish to employ smaller doses, have now prepared tabloids containing half-grain doses (0·032 gr.), put up in bottles of 25 and 100.

CROMESSOL.

(CROMESSOL COMPANY, 140–148, BRAND-STREET, IBROX, GLASGOW S.W.)

We have received a sample of this pleasantly scented disinfectant and germicide. The basis of the preparation is formaldehyde, but essential oils which enter into its composition ensure that the pungent characteristics are considerably modified. Used according to directions and with the fine spray supplied by the Cromessol Company, offices and buildings can be quickly filled with a vapour which should effectively prevent the growth of noxious germs. The claims made for the preparation are entirely based on its protective value. Cromessol is prepared with the eau de cologne, verbena, lavender, and other essential oils and the preparation, which can also be used in the bath, does no injury to fabrics. Tested against 24-hour cultures of *B. typhosus* and *B. diphtheriæ* under similar conditions the disinfectant has been found to possess the germicidal power of standard carbolic acid solution, while the growth of *B. anthracis* was greatly inhibited. The effect of spraying upon vermin was marked; lice do not live more than six hours after being sprayed.

CREO-TERPIN COMPOUND (WAMPOLE).

(MESSRS. H. K. WAMPOLE AND CO., PERTH, ONTARIO. AGENTS: MESSRS. FRANCIS NEWBERY AND SONS, LTD., 31–33, BANNER-STREET, LONDON, E.C.)

Each fluid ounce of this preparation contains chloroform 1 min., terpin hydrate 4 gr., creosote purified 4 min., calcium glycerophosphate 4 gr., and sodium glycerophosphate 4 gr., with 26 per cent. of alcohol. The action of the compound is expectorant and deodorant. Used in bronchial complaints it is claimed to check cough and render the secretion less tenacious, while appetite tends to improve. Medical men may like to see how far these valuable actions would assist in the treatment of troublesome symptoms associated with asthma, whooping-cough, and catarrhal conditions of the respiratory tract. The compound is put up in 8 oz. and 16 oz. bottles, the suggested dosage being, for adults, one to two teaspoonfuls every three or four hours well diluted with water, and for children, according to age, from ten drops to half a teaspoonful. In coughs of a spasmodic or irritating nature, it is recommended that the dose should be held in the throat for a short time or used as a gargle before swallowing.

ALLISATIN TABLETS.

(SANDOZ CHEMICAL CO., LTD., PHARMACEUTICAL DEPT., BRADFORD.)

These tablets are a method of administering allium sativum in which the odour and flavour of the garlic have been got rid of by treatment with vegetable charcoal. It is claimed that, whereas other preparations of garlic present only a comparatively small quantity of some of the constituents of the plant, these tablets, each one of which contains 15 gr. of the fresh drug, employ the total sulphurous principles. There is good evidence that garlic is of service in gastro-intestinal affections, and a recent paper in the *Münchener Medizinische Wochenschrift* assumes this to be acknowledged, and, in particular reference to Allisatin, enumerates cases where improvement has followed its administration, while admitting the action of garlic to be not easily explained. Preposterous claims have been made for garlic with the result that its sensible indications may have been overlooked.

(1) NORMACOL; (2) NEO-REARGON.

(H. R. NAPP, LTD., 3–4, CLEMENTS INN, KINGSWAY, LONDON, W.C.)

"Normacol" consists of desiccated plant-mucus in combination with a small proportion of frangula glucosides, a crystalline glucoside extracted from the alder buckthorn, whose laxative properties are recognised. Administered in the treatment of constipation, the action of the drug is clearly intelligible. Owing to the property of expansion which the desiccated plant-mucus possesses, the effect is to expand the intestines and thereby lead to a defæcation reflex, while the glucoside is present in a proportion not sufficient to create an evacuation of the bowels, but sufficient to assist in the general action. There is no chemical irritant included, and the clinical tests suggest perfect safety for the administration of suitable doses to adults or children.

"Neo-Reargon" is a compound of anthraquinone glucosides and silver in ionised form, designed for the treatment of gonorrhœa of the anterior urethra in either acute or subacute form. The treatment is free from irritation, and with the absence of painful symptoms it is possible for the surgeon to proceed rapidly in an established case or to attempt an abortive result. Charts showing the strength of solution required in the various indications will be supplied to the medical profession, many of whom, we are informed, displayed much interest in the product at the recent London medical exhibition.

THE LANCET.

LONDON: SATURDAY, NOVEMBER 27, 1926.

PLUMBISM AND ITS AVOIDANCE.

THE Lead Paint (Protection against Poisoning) Bill has been debated as though the choice lay between regulating the use of lead paint and prohibiting it altogether. Prohibition is a policy unlikely to be adopted by the present Parliament without prolonged controversy. The choice may, therefore, be otherwise stated; it lies between obtaining regulation before Christmas and obtaining no legislation on the subject at all for some time. It has been said that the prohibition of lead paint in this country would reduce painting work by 40 per cent., and the Government is naturally loth to disturb industry or to increase unemployment unless it is absolutely necessary. It undertakes, however, to bring in a Bill to prohibit lead paint if the proposed regulations fail to give the protection now hoped for, meanwhile asking that the regulations be given a trial. The Bill gives some idea of the scope of these regulations. They may, where buildings are being painted, prohibit the use of any lead compound except in the form of paste or paint ready for use; they may prohibit dry rubbing down and scraping; they may deal with the danger of applying lead paint in the form of spray; they may provide for periodical medical examination and for the non-employment of persons whose health appears likely to suffer; they may secure washing facilities for painters both during and after work; and they may provide for protective clothing and the distribution of instructions as to the hygienic precautions to be taken. Finally, Clause 2 of the Bill, following the Geneva Convention, prohibits the employment of women and children in the painting of any part of a building with lead paint, on the grounds that in the case of women there is a greater susceptibility to lead poisoning, more rapid intoxication, and graver racial consequences. Politically the exclusion of women is resented by the advocates of sex equality, though similar exclusions have been upon our statute-book for 35 years and though two fresh instances were enacted in 1920 without evoking much protest. The other opposition to the Bill comes partly from those who do not wish to see any further interference with industry by Government departments, but mainly from those who will not accept mere regulation of an industrial risk which, they say, should be altogether abolished. They demand the prohibition agreed upon by the Geneva Convention and will not accept the half-loaf now offered. Mere regulation, they consider, can never safeguard the ordinary house painter who works in private dwellings either by himself or in small groups and thus cannot be subject to adequate official inspection. Britain, they say, agreed to prohibition at Geneva and she must not dishonour her signature; the country which has led the world in welfare legislation must not turn reactionary now. The defenders of the Bill reply that there was no signature to dishonour, and that this country in no way bound itself to any course of action; they believe that regulation can make the industry reasonably safe. Trade-unions will tell their members of the risks and the prescribed precautions, and medical examination will play its part in detecting the onset of disease. Medical science is thus expected to answer two main questions: Can any—and, if so, what—regulations sufficiently protect the lead paint worker? and Have women a special susceptibility to lead? In another column (p. 1132) we summarise some of the evidence on these two questions.

Some industries have had experience of the value or otherwise of regulations, though the statistics as to lead poisoning in the potteries are being freely used by both sides. According to British experience, white lead manufacture, work in potteries, and metal smelting seem to carry a graver risk of plumbism than painting, and it appears that in any lead trade the chief danger is from dust or fumes. Many authorities, especially in this country, consider that lead enters the system chiefly through the respiratory tract. Others regard the digestive tract as the principal channel of entry, and it has been stated that experiment shows that whereas only 12 per cent. of lead dust enters the lungs, about 70 per cent. enters the digestive tract after settling in mouth or nose. "Whatever be the truth," as the International Labour Office [1] says, "this discussion, from the practical point of view, is of only secondary importance, the campaign being really waged against the great enemy—dust." How, then, does lead affect workers in paint? The painter using paint already mixed incurs only the slight risk of ingesting small amounts of lead—e.g., from his paint-smeared fingers. But if he uses sand-paper on painted surfaces by the dry process, he inhales large quantities of dust. The regulations prohibit this dry process, and their supporters expect much from this provision. The Bill does not, however, specifically guard against the inhalation of lead oxides when the workman burns off paint with a blow-pipe, which is regrettable since inhalation of small amounts of insoluble lead compounds may be very dangerous. It is, indeed, a characteristic of lead that it acts in very small doses. The amount required to set up chronic plumbism has been estimated as low as 1 mg. of dust inhaled daily, and 10 mg. sets up severe symptoms in a short time, though there is reason to think that animals and human beings may acquire a tolerance under certain conditions. American and German research shows that lead compounds, inhaled and ingested, are stored as an insoluble phosphate in the skeleton. This may be gradually mobilised and excreted, and in passing through the blood stream may produce toxic symptoms. Detailed analyses of human tissues have proved that workers in dusty lead trades may have from 0·5 to 1·0 g. of lead phosphate in the skeleton. In the course of a speech against the Bill in the House of Lords on Nov. 18th, Lord DAWSON referred to the use which could be made in industry of a biochemical test for the susceptibility of individuals to lead and the degree of poisoning reached, and there is no doubt that if so dangerous a substance as lead is to be employed at all the workers ought to be frequently and carefully examined, not merely for crude paralyses but for slight deviations from health. The Government describes its proposals as an experiment, and it is an experiment that will only succeed if employees are kept under thoroughly efficient medical supervision. The Government's opponents describe the experiment as gambling with men's lives, but as we have pointed out, the choice at present appears to be between the regulations and nothing, and it is gambling with lives to leave things as they stand. The Government has given its pledge to introduce prohibitive legislation if the present regulations fail and in the meantime it would be well to accept substantially

[1] International Labour Office, 1926. Brochure No. 54: Lead Poisoning.

what is offered. It is regrettable that the system of control rather than prohibition will involve further inspection and State interference with an industry, but an element of compulsion does not necessarily exclude the education which is the only satisfactory basis of industrial hygiene. Education should be all that is needed, for it is to the interest of everybody —employer and employee—that poisoning should not occur. The continued existence of the problem, however, seems to show that education requires temporary reinforcement.

The attempt to prevent women from working with lead paint has given rise to much controversy. The argument that women (or men) can be left to look after themselves is unconvincing; if it were accepted it would mean that the State should never introduce legislation governing the conduct of factories; it ignores the unpleasant fact that many workers in this country to-day are forced by circumstances into certain forms of employment whether injurious or not. The Government's proposal to exclude women suggests a lack of faith in the new regulations as a safeguard against lead poisoning. Granted that a considerable risk is still being run the exclusion is based on (1) the higher susceptibility of women, (2) the graver effects of poisoning in women, and (3) the danger of lead producing abortion or the early death of children. Evidence on each of these questions will be found in the special article referred to. There is no doubt that the older statistics on lead poisoning in women are largely fallacious because women were given the most dangerous jobs in the industry and were badly paid and underfed. The International Labour Office [2] states that "while English opinion inclines to the view that women are more susceptible to the action of lead than men this is not accepted by German writers who consider that their poor state of nutrition, poverty, industrial fatigue, added to housework, long hair, and type of clothing favouring the accumulation of a greater quantity of the poison upon them, are sufficiently potent factors to account for the apparent disparity. Data from the United States are not sufficient to allow the experts to support either of these views. All, however, agree that in women lead poisoning assumes a more severe form. . . . than in men." This is a very important fact; but when supporters of exclusion speak of the effect of lead on female fertility they are certainly not on sure ground, for chronic poisoning of the father appears to be almost as damaging to the ovum as chronic poisoning of the mother. Lord HALDANE will have sympathy for his plea for further medical guidance on this question before rash assumptions are made. The general admission that lead poisoning does more damage when it affects the female is a sufficient ground, perhaps, for excluding women from the industry as at present conducted, but the new regulations will be a failure unless they make the work reasonably safe both for men and women.

ACUTE POLIOMYELITIS.

ACUTE poliomyelitis is regarded with particular anxiety by the physician, for he cannot say, in a given case, whether the crippling and disabling sequelæ will make their appearance in a mild or in an aggravated form, and cannot determine from the prodromal symptoms whether involvement or escape is to be the upshot. No clear relation has as yet been established between the mildness or otherwise of the initial syndrome and of the paralytic consequences, so that the knowledge that the cases in which the latter develop actually constitute the minority is but cold comfort. Unfortunately there is a clinical type, also, in which the early febrile symptoms are so trifling as practically to escape notice, amounting in some instances to nothing more than a headache; the fulminant onset of paralysis in some such cases exemplifies the serious nature of the disease's uncertainties. Again, even when invasion of the lower motor neurones, restricted or widespread though it be, is clinically obvious, prognosis as regards recovery cannot readily be estimated by any known criteria, for the residual incapacity bears no constant relation to the severity of the symptoms during the first few days. If such means as we at present possess for a rational treatment of epidemic poliomyelitis are to be of any service, it is clearly imperative that the condition should be diagnosed in the pre-paralytic stage—during those precious two or three days that in the great majority of cases supervene between the febrile onset with malaise and the revelation of lesions in brain or cord by paretic or paralytic symptoms. When epidemic disease of whatever kind is raging the profession and the public are on the alert, and there is considerably less likelihood of abortive and incomplete cases being missed; in respect of poliomyelitis at the present time we may believe that an attitude of watchful and solicitous care has been adopted by all whom it concerns. To diagnose the disease at the earliest, the following considerations are apposite. As a rule the illness is not so severe or so obvious as to "fell" the child and make it take to its bed at once. With a moderate rise of temperature, headache, sickness, malaise, possibly with mild catarrh or throat symptoms, there is no outstanding clinical feature to suggest any one infective condition rather than another; should spontaneous pains be complained of, in neck, back, or limbs, with or without a corresponding hyperæsthesia, the indications point more specifically to irritative phenomena on a meningeal basis. Lumbar puncture must in any and every case of this kind be performed at once if suspicion is aroused; by fluid examination varieties of meningitis can be differentiated from poliomyelitis, and the latter can be distinguished by the increase of cells, which is a constant feature of this pre-paralytic stage, by normal glucose and chlorides, and by little or no protein change. The cells vary from, say, 30 up to many hundreds per c.mm., some 60 to 90 per cent. being polymorphonuclear. A fluid finding of this kind, with absence of organisms, is highly suggestive of acute poliomyelitis, and much less indicative of epidemic or lethargic encephalitis, since in the latter the polymorphonuclear element is almost entirely absent from the cytology. Finally, in this connexion, the pre-paralytic period is signalised by diminution or loss of the deep reflexes in many cases, sometimes as long as 24 hours before actual paralysis is detected.

Should the application of these considerations to a particular case enable the observer to make an accurate diagnosis, the sole *specific* treatment consists in intraspinous injection of immune serum, a method which has been used with success in previous epidemics. To obtain this serum is the difficulty. It is known that an attack of poliomyelitis confers immunity on its subject for years, and that the patient's serum remains active against the disease for a very long time. But how, as a matter of practical therapeutics, can the physician find a convalescent or an old case at hand, the patient being willing to give the necessary blood, precisely when an acute case of poliomyelitis

[2] Ibid.

in the pre-paralytic period presents itself for immediate treatment? If this difficulty can be met, the procedure is simple enough; the serum is separated from, say, 30 c.cm. of the giver's blood, obtained by venepuncture, warmed, and injected into the spinal theca by the lumbar route in amount corresponding to the quantity of fluid withdrawn—say from 4 to 12 c.cm. This treatment can be repeated daily for some days. It is useless except when employed before the paralysis has set in definitely, or in cases of a progressive ascending character. Efforts have been made by many workers to obtain varieties of animal sera which have been appropriately treated so as to contain actively immunising bodies, but as yet the results have been uniformly disappointing. One of the great difficulties, as FLEXNER and AMOSS[1] have emphasised, is that only two varieties of the virus of poliomyelitis have as yet become known; one is too weak to excite any reaction in the experimental animal, and the other is so strong as to induce severe paralytic effects in the monkey. Artificial attenuation of the virus must somehow be effected before further advance can be made. No medicinal agent hitherto has been proved to exercise a beneficial influence on the course taken by the disease, but much can be done to minimise the ultimate sequelæ by insisting on absolute rest in bed, at least for three weeks, and by concentrating on the muscles that are affected. What the physician must aim at is to obtain the "zero position" for them—i.e., that position in which a given muscle is completely relaxed and its opposing muscle is prevented mechanically from exercising its action, by appropriate splinting or the use of plaster "shells." If weak muscles are placed in a position of relaxation from the outset, many of the deformities of the later stages will be effectually prevented. Individual thought is obviously required for each case, but the principles are the same in all—no loading or stretching of an atonic muscle is to be allowed. Bearing in mind the spinal site of the lesions, the physician will utilise all available means to maintain the nutrition of the affected muscles until such time as recovery takes place from within. Hence there is a place in his therapeutic scheme for the employment of warmth to the limb or limbs, skin friction, warm baths and douches, and gentle massage and movements; the former should be carried out from the beginning, the latter after the first week or two are over. Electrical applications of a stimulating kind are probably less advantageous than is commonly supposed, and in any case are not called for at the early stage.

The incubation period of poliomyelitis has been determined within the range of from four or five days to ten or twelve. Being infective if not infectious it requires that isolation should be adopted; according to the experience of many observers, in a hospital bed-isolation suffices. The virus has been found in the nasal, buccal, and pharyngeal mucous secretions both of patients and of contacts and others who have exhibited no nervous symptoms and sometimes no general symptoms. It is a good plan, therefore, for the practitioner to insist on regular nasal and throat douching or gargling with washes of potassium permanganate or some variety of chlorine-containing solution, on the part of contacts and patients alike. The evidence of the spread of infection by schools is certainly not strong, just as that of spread through a ward of a general hospital is for all practical purposes nil. In one of the Massachusetts epidemics only 35 patients out of 150 cases were attending school, and of the 35 no less than 22 attended different schools. The occurrence of the disease in institutions is as a fact extremely rare. In view of what was said above of the incubation time, a quarantine of a fortnight before contacts return to school should be sufficient. More difficult to evaluate is the period at which infected patients may be considered free from infection. Possibly the virus remains in the mucosæ for months. Those cases which recover quickly are perhaps less serious in this respect; one month at least should elapse after convalescence is complete ere the patient is allowed to resume his place at school. The view here adopted was well set out 15 years ago in a paper by the late Dr. F. E. BATTEN, communicated to the Association of Medical Officers of Schools.

FOG AND MORTALITY.

WE publish elsewhere in this issue an interesting study by Mr. W. T. RUSSELL, from the Medical Research Council's Statistical Department, of the arithmetical relation between temperature and fogginess on the one hand and mortality from respiratory disease on the other. This paper well illustrates both the strength and the weakness of the statistical method in such problems.

The strength of the method resides in this, that it enables one to give a *rational* answer to the sort of question we are always asking. We are all of us, medical men and laymen, prone to seek some numerical answer to such questions as—How many lives would be saved annually if tuberculosis were conquered? How many lives are saved annually by the reduction of infant mortality?—and in this class of question one directed to the numerical saving of life to be attained by a less barbarous utilisation of fuel is often to be found. But the common way of answering such questions is somewhat crude. It consists in comparing the mortality over a period when the factor whose influence we desire to measure is operating intensely, either with some average mortality or with the mortality in some other period when these factors were less in evidence. Thus we find the greatest of medical statisticians, WILLIAM FARR, writing: "The effects of the cold of the five weeks that ended on 19th of December (1874) have been tested in the same way by comparing the deaths at each age with the deaths in the five previous average weeks. The deaths were raised from 6967 to 9871; so the excess due to cold was 2904 in the five weeks, and on an average 581 weekly." FARR—who was fully alive to the many statistical difficulties, indeed he said that any investigation which "is confined in its scope to *mean* temperatures must be imperfect"—would have been the first to admit that this is too summary a way of assessing damages. The modern statistical calculus provides a better measure. Mr. RUSSELL did not have to confine himself to contrasting particular periods; he could measure the average relation. While to obtain a numerical assessment of the damages chargeable to fog and temperature, his equation which tells us how much for each fall of a degree of temperature below the normal for season or for each unit change in the measure of fog the number of deaths will be altered. For instance, in his most favourable case, the deaths of the nineteenth week of the year related to the temperature and fog of the previous week, a change of one degree of mean air temperature corresponds to an increase or decrease of nearly 2 deaths (almost 5 per cent. of the mean mortality in the two boroughs studied) and one unit change in the fog standard corresponds

to 0·25 deaths. Nor is this a mere formal relation, because, as Mr. RUSSELL points out, given the temperature and fog measure of one week, it is possible to make an appreciable closer estimate of the mortality in the following week than if we have not that information.

These considerations show the strength of the method. Its weaknesses are not less apparent. In the first place, as Mr. RUSSELL clearly points out, and as FARR noted 60 years ago, the numerical measure of temperature is very imperfect, while the measure of fogginess is even more open to criticism. In the second place, equations are good servants but bad masters. With the equations provided by Mr. RUSSELL, the injudicious might reach very surprising conclusions. They might conclude that in the fourteenth week of the year fog was a positive benefit to health, the more of it the fewer the deaths, or, worse still, they might conclude that warmish weather with thick fog was much healthier than cold weather with no fog at all. We are not prepared indeed to say that this statement is *certainly* false (we believe it is false), but only that the equations do not demonstrate it to be true. All they amount to is a summarisation of experience over a comparatively narrow range of physical conditions, and to suppose that they hold good beyond the range of observation would be as rash as to expect any interpolation formula to be valid beyond the range of observations; if it were, anybody could be a successful prophet. We may, perhaps, regard it as proven that (1) temperature and mortality from respiratory diseases are substantially correlated; (2) that fogginess and mortality are also correlated, but that the latter relation cannot, upon the present data, be demonstrated to be so close. Rightly to appraise the relative weights of these two factors is impossible without a more precise measure of "fogginess," and, indeed, a differentiation of the various physical types of fog. Such information was not available for the period taken by Mr. RUSSELL, and, since 1890, the return of influenza has greatly complicated the statistical problem. Hence it is probable that it will be long before statisticians can give an answer to the question—What does fogginess cost in lives?—which is not only *rational* but *exact*. We may even hope that, before the statistician has sufficient data to give the answer, urban fogginess will have been abolished on general principles, for the cumulative effect of the evidence that fog is indeed an unmixed evil is overwhelmingly great.

DONATIONS AND BEQUESTS.—Miss Mary Scott Mouat, of Lanthill, Malvern Wells, left £1000 to the Royal Manchester Children's Hospital for the endowment of a bed "in memory of her sister Margaret."—Mr. Arthur Donald Oates, Halifax, left £1000 to the Royal Halifax Infirmary.—Mr. Thomas Oxley, Blackpool, who left estate valued at £32,107, gave £1000 each to the National Institute for the Blind, Great Portland-street, the Y.M.C.A., Sheffield, and the Sheffield Cripples' Aid Association, and, after other bequests, the residue of the property, which will amount to about £20,000, to the Sheffield Royal Infirmary.—Miss Edith Jameson Robinson, Dawlish, Devon, left £1000 each to the Dawlish Cottage Hospital and Dr. Barnardo's Homes.—Messrs. Bourne and Hollingsworth, London, have given £4000 towards the Reconstruction Fund of the Middlesex Hospital as a mark of appreciation of what the Middlesex Hospital does for the benefit of workers in their immediate neighbourhood and for their own employees.—Miss Rachel Pennywick, of Craigie, Perth, besides other bequests, left £1000 each to Perth Royal Infirmary and the Elgin Hospital, and £200 each to Burghmuir Infectious Diseases Hospital, Perth; Hillside Sanatorium, Perth; Friarton Fever Hospital, Perth; and Perth Children's Day Nursery.—Under certain conditions and subject to his wife's life interest, the late Mr. Henry Edwin Fraser, of Glen Albyn, Station-road, Hendon, N.W., left £1025 to Middlesex Hospital for the endowment of a bed.

Annotations.

"Ne quid nimis."

DOCTORS AND STATESMEN.

THE annual dinner of the Royal Society of Medicine on Nov. 18th was marked by three interesting events. One was the presentation of the Society's gold medal to Mr. J. S. Haldane for his great services to medicine and science. The second was the gift of a seventeenth-century gold chain by Sir StClair Thomson, to be worn by the President as his badge of office. The third was the presence of the Rt. Hon. Stanley Baldwin as guest of the evening. The Prime Minister took advantage of the toast of "The Society" to make a happy speech on the similarity between the functions of medicine and statesmanship. Both professions, he said, owe a profound debt to the Greeks; the common goal of both is the attainment of perfect health and normal balance of function. Both deal with an infinitely complex assembly of growing structure, never at rest, and subject not only to distemper but to disease. Both suffer from plenty of quacks and charlatans, who seek to heal the sick by reciting magical formulæ which they call "slogans," and physician and politician alike are apt to have trouble with those members of their callings who either will not or constitutionally cannot keep out of the Press—a rash that appears on the most unexpected persons. Both are subjected to the attacks of those who differ from them. Mr. Baldwin, however, gave to the doctors the advantage in that they do sometimes receive emoluments appropriate to the confidence reposed in them by the public. They have sometimes, too, he said, the inestimable advantage of seeing the results of their work, and those who rise up and call them blessed are beyond all enumeration. For the politician there is only the laying of foundations for generations ahead, and the land he would see is as the hills that are very far off. The temperature of the body politic varies almost as rapidly as temperatures measured by the clinical thermometer. Last May it might well have reached 105°, and there are still symptoms of fever, due to attacks of a very virulent epidemic that the Prime Minister ventured to diagnose as "Russian influenza." Epidemics tend to become less severe as time goes on, but until that disease diminishes in strength or some vaccine to produce immunity is found, he could promise us no relief from intermittent fever. The body politic needed, he said, a Harvey to find out the mysteries of the cyclic ebb and flow of unemployment, but the surgeons, who would operate on the House of Lords as on an appendix, were in his opinion less necessary than physicians.

Sir James Berry said "Happy is the nation that has no history," but went on to indicate that the Royal Society of Medicine may be called a happy nation, or, as the Prime Minister said, an Empire, while its history is of great interest. He referred in appropriate terms to the recent development in the *Proceedings*, and went on to mention the many improvements which have been carried out in the building and equipment during the last twelve months. Sir James Berry dwelt on the ideal to extend the services of the Society to the poorest practitioner, but uttered a serious warning against a too great prevalence of operating. The extension of the already remarkable library facilities, he said, is an earnest of what the Society will accomplish if it gets adequate support, but it is at present hampered by a capital debt of £25,000. Donors, as Sir James Berry said, are attracted to the laboratory, but the research work performed in the Society's library should not be underestimated. Dr. Robert Hutchison, in proposing the health of the guests, continued the Prime Minister's analogy by coupling him with the medical profession under the late Lord Salisbury's encomium of a "great social cement." Sir William

Bragg pointed out in his reply that physicians and physicists had always lived in the closest of alliances, and that when the Royal Society was first founded the physicians of London had been the keenest participants in the exciting early discussions. Sir Berkeley Moynihan, who also replied to the toast, urged it as vital that the medical profession should keep constantly in view their duty of maintaining intimate touch with the lay public and of fulfilling their obligations as citizens, which they did not lay down when they qualified. However the medical profession fails to reach its ideals, it continues to pursue them ardently, and ideals are, he said, not so much for capture as for pursuit. The whole of Sir Berkeley Moynihan's witty speech, in which he made constant happy references to the whimsical fantasies of "The Mikado," was directed to show the necessity that doctors, who in the war had displayed great administrative gifts, as well as technical skill, should in times of peace play a similar part in coöperation with public efforts.

CUTANEOUS XANTHOCHROMIA.

IN 1913 H. van den Bergh, while making investigations on the different pigments in blood serum, drew attention to xanthosis in diabetics and recognised the lipochromic nature of the pigment on which it depended. A little later, Labbé described under the name of xanthochromia palmoplantare an intense yellow coloration of the palms and soles met with more or less frequently in cases of diabetes. His conclusions, after laborious experiments, tended to exclude cholæmia as the cause of the coloration, there being no excess of bilirubin in the serum or urine; the colour seemed attributable to a different pigment of unknown nature. Xanthochromia is observed especially in diabetes and mostly in severe forms of this disease. On the other hand, it may be present in many other affections, such as typhoid fever and in subjects showing the marked disturbance in nutrition which often precedes diabetes. Subsequently Labbé and his pupils conceived the idea that a high cholesterol content of the blood might explain the pigmentation; but they found, after diligent investigation, that xanthochromia did not coincide invariably with hypercholesteræmia, being relatively much less frequent. In fact, conditions of increased cholesterol content are found without there being the least sign of xanthochromia. Thus a marked condition of hypercholesteræmia has been described in various forms of nephritis—precisely in those which are associated with lipoidosis and cholesterinosis of the kidney—and in the course of many hepatic disorders, such as cholelithiasis, Weil's disease, obstructive jaundice, acute yellow atrophy, cirrhosis and cancer of the liver. In tuberculosis, especially when of long standing and with amyloid degeneration, there may be hypercholesteræmia, as also in severe forms of anæmia, and in syphilis, chronic alcoholism, and arterio-sclerosis. Among physiological conditions characterised by constant hypercholesteræmia are pregnancy, the menopause, and, to a slighter degree, senility. Yet in none of these conditions with a constant more or less high blood content of cholesterin is there a concomitant xanthochromia. Dr. V. R. Peretti, of the University of Naples, has recently published[1] some investigations on the subject which are of interest. It is known that the pigment which colours the serum is a lipochrome, lutein, a complex hydrocarbon of the aromatic group; it may be estimated in the blood by van den Bergh's method. Dr. Peretti made observations on 17 cases, and found that seven were diabetics, with xanthochromia, cholesteræmia and lipochromia; five were diabetics without xanthochromia or lipochromia, but with cholesteræmia only; two were obese subjects not diabetic, but with acidosis, xanthochromia, and lipochromia; and three were rare and spurious cases of xanthochromia and lipochromia in patients who were not diabetic and had no cholesteræmia. It will be seen that in these seven cases lipochrome bore a definite relation to the xanthochromia and was associated with a high cholesterol content; yet hypercholesteræmia occurred also in the five cases in which there was no xanthochromia. Moreover, it appears that the lipochrome content varied proportionately to the intensity and extent of the xanthochromia. A priori, therefore, it must be admitted that xanthochromia is due to the accumulation of lipochrome in the blood and tissues. This conclusion is confirmed by the three spurious cases, in which there was xanthochromia without diabetes or cholesteræmia, in whom lipochrome was also found. As regards the origin of lipochrome, van den Bergh found by experiments that it was possible to vary the amount of it in the blood by giving substances alternatively rich or poor in such pigments; he isolated and called carotin and xanthophylla, pigments contained in carrots and green vegetables, and present as lutein in egg-yolk, where they, apparently, facilitate the combustion of fats. Dr. James Oliver has recently called attention[2] to carotin in the blood-serum as a probable halogen-carrier. But the importance of diet in explaining lipochromia—however easily assumed and suggestive—does not carry full conviction, since it is a matter of daily observation that not all diabetics who are on a largely vegetarian régime, nor the tuberculous, who eat large quantities of eggs, show signs of xanthochromia. The lipochrome introduced into the organism does not remain there passively or indefinitely, but is either destroyed internally or eliminated by the excretions, and the conclusion which this suggests is that the essential cause of xanthochromia is to be found in the patient's incapacity to get rid of the ingested lipochrome by excretion or destruction. Dr. Peretti lays the blame on faulty general metabolism, and in favour of this cites the fact that diabetics with severe and extensive xanthochromia show a marked disturbance in fat metabolism, a defect in the combustion of the ketonic fatty acids, and an accumulation of cholesterol. In the same way xanthochromia is met with in the obese, who, although not diabetic, present an almost chronic acidosis, indicative of inefficient fat metabolism. The most satisfactory conclusion to be drawn from all this evidence seems to be that xanthochromia palmoplantare should be considered as a phenomenon of purely clinical interest, since it has no serious prognostic significance.

THE 1924 OUTBREAK OF ENCEPHALITIS IN SHEFFIELD.

THE last plague to escape from Pandora's box has proved in some ways to be the worst, although, in the Report[3] before us, Prof. F. E. Wynne says that statistical estimates of the fatality of epidemic encephalitis should be accepted with reserve owing to the occurrence of unrecognised mild and abortive cases. The main features of the Sheffield outbreak of 1924 have already been set out in our columns, and this Report contains the considered opinions of epidemiologist, pathologist, and clinician upon its lessons. Prof. Wynne is unable to establish any relation between the disease and social conditions, such as overcrowding, poverty, or insanitary housing, nor any relation with site, water, milk or food-supply. There is no trustworthy evidence that it is spread by direct contact nor any data for computing an incubation period. The only positive evidence concerns the greater liability to infection in males and the greater liability to die of the disease in females. Prof. J. S. C. Douglas's pathological report is brief, for the results closely corresponded with those found in other outbreaks. In the clinical report by Prof. A. J. Hall and Dr. A. G. Yates the difficulty of diagnosis is emphasised, for 16 cases notified as epidemic

[2] Med. Press and Circular, Nov. 17th, 1926.

[3] Medical Research Council. Special Report Series No. 108. The Sheffield Outbreak of Epidemic Encephalitis in 1924. H.M. Stationery Office. 1926. 1s. 9d.

encephalitis proved to be suffering from some other condition. Although about one-half of the cases notified could be described as mild, with a tendency towards complete recovery, Parkinsonism was found not infrequently to follow an attack of extreme mildness. Ocular palsies persisted rarely, although an occasional speech difficulty remained for considerable periods. Mental disorders persist in half the cases in which they were acute in the primary attack. Sleep disorder tended to chronicity, in many cases taking the form of nocturnal insomnia. The occurrence of moral changes during the primary attack was too difficult to assess, so long as the patients were in bed under strict nursing supervision, to afford material for report. Respiratory disorders in the primary attack did not persist in any case. The time of onset of Parkinsonism was most commonly from 6 to 12 months, the facial mask appearing early. Five out of 64 cases so affected have died already, while of the remainder a considerable percentage is getting steadily worse; about half seem to be at a standstill. Of the 43 patients with encephalitis who did not survive, 40 died within two months of onset, two of pneumonia several months later, while one boy died eight months after a mild primary attack of what appeared to be a recurrent acute attack with profound lethargy. An appendix to the Report contains a summary of recent researches by Dr. J. R. Perdrau from the National Institute for Medical Research at Hampstead. Dr. Perdrau's study of immune reactions in the rabbit confirms the contention of Levaditi and others that the causal agent of encephalitis is identical with that of herpes febrilis, except in regard to the greater affinity of the former for the central nervous system. He admits that the theory of herpetic origin has not been universally accepted by research workers, although no other theory has so far been propounded on experimental grounds.

PROLAPSE AND CARCINOMA.

SOME recent reports of the occurrence of carcinoma in a prolapsed uterus only serve to show how surprisingly rare the condition really is. Last March Dr. H. Leith Murray, giving the history of a case[1] to the North of England Obstetrical and Gynæcological Society, said that he had been able to find only one instance of carcinoma with prolapse recorded in the journal of *Obstetrics and Gynæcology of the British Empire*. This was described by Dr. Russell Andrews in 1910 and had something in common with his own, for in both the history of protrusion at the vulva was only recent; in Dr. Murray's the cervix had bled freely ever since its appearance. Before the same society on Oct. 15th Dr. J. W. Bride gave an account of two cases in which prolapse was associated with malignant disease. In the second of them the lesion was a primary carcinoma of the vagina which, he said, might possibly have been caused by neglect of a rubber ring pessary worn during the previous five years. The first case, however, was one of cervical cancer, where no pessary had ever been worn.

The patient was a woman of 50 who had had six children, the last of them ten years ago. She consulted Dr. Bride in June, 1921, complaining of a bad discharge, brownish and watery, and of something coming down. On examination it was found that she had a complete prolapse with hypertrophy and severe ulceration of the cervix. At operation on June 10th, 1921, though the cervix did not seem to be definitely malignant, Dr. Bride removed the uterus by vaginal hysterectomy in the course of an extensive anterior colporrhaphy according to Fothergill's method. The pathologist reported that there was a columnar-celled carcinoma of the cervix and the patient made an uninterrupted recovery. In April, 1925, she returned complaining of a small ulcer on the right labium majus, which had first been noticed in the previous December. The vulva and glands were excised on April 8th and microscopical examination showed epithelioma of the vulva. Recurrence took place at the end of that year and radium was applied on two occasions. She died about three months ago.

Discussing this history, Dr. Bride said that he thought that the association of the columnar-celled cervical carcinoma and the vulval epithelioma was almost certainly fortuitous. At any rate, it appears irrelevant to the question whether prolapse predisposes to cancerous change. In looking at this question it would be reasonable to suppose that a protruded cervix, constantly subject to irritation, would stand a good chance of becoming malignant, but, as Dr. Bride pointed out, authorities such as T. S. Cullen and G. Panton have been able to collect so few cases that they could only regard the coincidence of prolapse and cancer as accidental. There is no doubt that childbearing predisposes to carcinoma of the cervix, and the most generally accepted explanation of this fact is that the laceration so often caused in labour becomes the seat of a chronic inflammation, and this is the starting-point of a new growth. The irritation thus caused can rarely be so great as that suffered by a cervix projecting at the vulva; yet it almost seems as though cancer is less common with prolapse than without it. One explanation that may be put forward to account for its rarity is that ulceration due to protrusion of the cervix seldom lasts long enough to cause cancer of itself. In general a long period elapses between the beginning of ulceration and the development of clinical carcinoma, and presumably, not all patients with chronic ulceration are in such physical condition that they are liable to develop cancer; the number of susceptible persons who suffer for a long period from gross prolapse is probably very small. The same argument—that the latent period is usually long—may be used to explain why pessaries in the vagina so rarely give rise to carcinoma, although they usually set up a mild chronic inflammation and occasionally cause pressure ulcers of the walls. Dr. Bride's case of vaginal cancer quoted above is uncommon enough to prove the rule.

THE RED CROSS AND DISASTER RELIEF.

A PICTORIAL supplement to *World's Health* for November shows how intimately the Red Cross movement has become associated with the relief of distress in the face of national calamities. It was from the first the desire of the founders of the League of Red Cross Societies to furnish a medium for coördinating relief work, whether national or international. To improvise relief on the spot is a long, painful and inefficient method, and the League is becoming a clearing-house of information with a view to avoiding duplications and waste of effort. Special reports were presented to the Second Oriental Red Cross Conference which has just concluded its sittings in Tokio. A brilliant example of organised relief was given in America three months ago. It will be remembered that on Sept. 18th a hurricane swept over the Atlantic coast of Florida in a tract 60 miles wide, destroying and damaging numerous buildings and disorganising the electricity, water, and gas services of Miami, a large and popular winter resort. The number of persons killed was 106; 857 were injured, and thousands were rendered homeless. The immediate demand for relief work of all kinds was naturally overwhelming, and help was soon forthcoming from all parts of the Union. From a wealth of determined efforts at rescue that of Chicago stands out as an example of almost perfect team-work and leadership. The initiative, as apparently in most great public enterprises in the States, was taken by the Press, and the *Chicago Herald-Examiner* (the headquarters of the Hearst combine) decided to despatch a relief train to Miami. The civic authorities placed the whole public health service at Mr. Hearst's disposal. The Commissioner of Health, Dr. H. N. Bundesen, to whom we owe a graphic account of the expedition,[1] was made director of the relief unit. The Illinois Central Railroad Company and the Pullman Company provided a special train with five sleepers, a dining car, two luggage vans and full personnel, free of charge. The county government board and the local hospitals allotted 33 physicians and 47 nurses. The train also

[1] Chicago's Health, Oct. 5th, 1926.

carried an X ray apparatus and two operators, an engineer with four complete chlorinator units, ten days' provisions, medical and surgical stores, clothing, ten 100-lb. cylinders of chlorine, and a ton of chloride of lime. The director had a headquarters staff of 12; two assistant directors, a railroad man, a liaison officer, a secretary, two motor-cycle police as messengers, and the sanitary and X ray personnel. Organisation and discipline was on the strictest military lines, and the unit was therefore mobile, highly efficient, and completely self-supporting. The director maintained full telegraphic communication with the civic authorities of the disaster area, and reported on arrival to the chief medical officer of the Citizens' Relief Organisation at his emergency headquarters. Before daybreak the expedition was transported in squads of 7–12 to the stations where their work could be of most value. Some squads worked in 12-hour shifts at emergency hospitals, others made house-to-house calls in outlying villages, relieved the staffs of regular hospitals or fed, clothed, and housed the destitute. In ten days the 100 members of the unit between them did 3945 dressings, performed 4426 operations, and gave 14,651 prophylactic injections.

The work of the sanitary staff was no less strenuous and important. The wells which supply Miami had all been polluted by flood-water. Chlorinators were promptly installed at two of the plants and at the principal station at Hialeah, which was waiting for its power to be restored. Next day the chief sanitary engineer was horrified to learn that Hialeah had come to life and had pumped half a million gallons of raw canal-water into the main to test it. He promptly arranged for chlorination at two points between Hialeah and the city distribution valve, but through some error of the local staff none of the chlorinators were operated and all this contaminated water entered the distribution system, just as the newspapers had sounded the "all clear." It soon appeared also that the operators of the pumping stations were neglecting to use their chlorinators. The director of the unit had to request the Miami Commissioners of Health to appoint shifts of supervising engineers at all stations, with authority to see that no unsterilised water was pumped through. Three days later the water was at last safe to drink. The inhabitants had, however, subsisted on flood-water for five days, and this fact may explain the very large number of antityphoid inoculations given by the medical staff.

The work of the Chicago train was so much appreciated, that when the Miami Commissioner of Health informed the director that the city could carry on by itself, the Mayor and other members of the local relief committee sent lengthy and urgent telegrams to Chicago for a two days' extension of its stay, which was granted. The American Red Cross described the unit officially as the best in every way that any disaster had yet produced, and, indeed, by every local account, it saved the situation.

THE DECLINE OF SYPHILIS IN EUROPE.

AT the first international congress for sexuology held in Berlin a week or two ago, Prof. Josef Jadassohn,[1] the well-known syphilologist of Breslau, reported the result of a questionnaire addressed by him to 51 specialists in 19 countries as to their views on the decline of syphilis and its relation to treatment by salvarsan. Almost all the syphilologists agreed with the explanation proposed at the German Dermatological Society in 1923 when the paramount importance of salvarsan in combating syphilis was emphasised as well as its relative harmlessness, provided proper care was taken in its manufacture and administration. In 14 countries there was unanimity as to the decline of the disease; in Italy six out of seven replies indicated a decline; in Russia statistics supplied by the Government showed a diminution of syphilis, but three practitioners returned a doubtful or negative answer, and one an affirmative; in Hungary and Bulgaria the decline of the disease was doubtful; in France there had been an undoubted decline to the extent of 50 per cent. from 1919 to 1923, but of recent years Jeanselme had observed a recrudescence in Paris and other centres which he attributed to the enormous immigration of foreign workmen and the substitution of bismuth for salvarsan. The decline of syphilis showed a considerable variation in the following countries—viz., in Denmark, Bulgaria, and Sweden by four-fifths, in England and Switzerland by a half, in Holland by three-quarters, and in Italy by a third. In 16 countries gonorrhœa had not diminished or had even actually increased, or lastly shown a decline, but by no means to such an extent as syphilis. Almost all the specialists were unanimous as to the cause of the decline of syphilis, which was to be found pre-eminently in the use of salvarsan. This explanation accounted for the difference between the decline of syphilis and that of gonorrhœa, in which disease treatment had not made any essential progress. More or less importance was attributed to accessory factors such as popular enlightenment, improvement in medical training, and the creation of treatment centres, especially of a gratuitous kind. The question as to whether salvarsan had exercised an influence on the frequency of tabes, general paralysis, and aortitis in a favourable or unfavourable sense was in many cases met by the reply that it was still too early to decide. Several observers declared that they had never seen a case which had been systematically treated with salvarsan from the first develop such sequelæ, and in no instance was an increase of general paralysis attributable to salvarsan. In conclusion, Prof. Jadassohn emphasised the importance of education, abstinence from alcohol, and improvement in housing conditions in the campaign against venereal disease.

EPIDEMIC PREVENTION IN CHINA.

SINCE the establishment of the National Epidemic Prevention Bureau at Peking in 1919 only two annual reports have been issued. This year the report has been replaced by a general review of the history and progress of the Bureau, with the object of making its aims better known and its services more extensively utilised throughout China. The establishment of the Bureau was authorised in June, 1918, by an order of the then Minister of the Interior, Ch'ien Neng Hsun, in an endeavour to follow the lead of the Western nations, and to prevent the recurrence of serious epidemics, such as that of pneumonic plague which swept the country in 1910 and again in 1917. The Bureau, which is directly under the Ministry of the Interior, is situated in the grounds of the Temple of Heaven. Its sphere of action has gradually increased until, in June, 1926, its four-fold functions were set out as follows: (*a*) research and teaching in connexion with the causes, prevention, and treatment of communicable diseases; (*b*) the examination and standardisation of materials pertaining to the prevention, disinfection, and treatment of these diseases; (*c*) the manufacture of vaccines, sera, and other therapeutic bacterial products; (*d*) the application of preventive measures against communicable diseases, and public health teaching and propaganda among the people. Distinguished Chinese and foreign specialists in preventive medicine and bacteriology are to be invited to act as advisers to the Bureau as occasion arises. The Bureau has already done useful work in cutting short epidemics of plague, cholera, typhoid, typhus, and small-pox in various parts of the country. During the war between the Kuominchun and the Fengtien factions in 1925–26, over 3000 wounded soldiers were segregated at the emergency hospitals at Nanyuan. Several medical officers from the Bureau went down to Nanyuan and gave tetanus antitoxin injections to 1352 wounded soldiers, most of the patients receiving 1500 units each. Of those immunised, not one

developed tetanus, while 30 out of 2000 men who were not injected died from the disease. This was the first time in China that extensive immunisation against tetanus has been given to the wounded. The administration of local public health measures has hitherto been almost entirely neglected in China. In May, 1925, the Bureau obtained permission from the Peking Metropolitan Police Department to establish a public health demonstration station in Peking. The type of work undertaken at this station includes a division of general sanitation; a division of public health medical services—e.g., infant welfare and industrial hygiene; a division of communicable diseases; and a division of vital statistics. Preventive inoculation against small-pox has been steadily growing, 4812 persons having been vaccinated by the Bureau last winter as against 27 in the year 1923. The importance of trustworthy vital statistics as a basis for national public health work is beginning to be recognised in China, although in the absence of a strong centralised Government the work is beset with difficulties.

AUTUMN SESSION OF THE DENTAL BOARD.

IN his address from the chair at the opening of the eleventh session of the Dental Board of the United Kingdom (the name has this week become an anachronism), Sir Francis Dyke Acland spoke of the important event in the dental world which had marked the period since he last addressed the Board—namely, the universal adoption of dental treatment as an "additional benefit" under the National Health Insurance Act, accompanied by a new scale and conditions of service. This, he said, would undoubtedly mark a very great advance towards the improvement of the health of our nation if the scheme was properly utilised. But in spite of the careful and admirable work of the Dental Benefit Joint Committee it would take time for the new system to settle down into good working order. The dental profession, he doubted not, would endeavour to work under the scheme with loyalty to it, and would even welcome the assistance of the regional dental officers in deciding questions which must need arise. But on occasions of this sort he could not help wishing that there were a higher standard of general education among a greater proportion of our people so that they might be more ready to utilise fully and properly the skilled services which are now at their disposal. Even if all the schemes of our education, health, and insurance authorities were to work as well in practice as they were meant to work on paper, their best efforts were liable to be undermined during the ages 14 to 16, between the times when the good habits of school days were apt to cease, and when employment within the sphere of Health Insurance began. "I believe," he said, "that the Board might usefully devote a considerable amount of its propaganda work to impressing upon juveniles at this very important period of their lives the importance of care for their teeth, and to explaining to insured persons, even more than we have hitherto done, the new duties and opportunities which the extension of dental benefit presents to them." In pursuance of this object the Dental Board decided to allot £4000 out of its available surplus of £31,100 to dental health education, along with any unspent balance from the previous year. The remainder was allotted thus: grants to students £21,000, grants for research £5000, post-registration lectures £600, and post-graduate lectures £500.

THE LATE DR. E. M. DE JONG.—On Nov. 15th Dr. Edward Meyer de Jong, died at Manchester in his sixty-sixth year. A son of Mr. Edward de Jong, the flautist, he was educated at London University and Owen's College, Manchester, qualifying in 1886. After a house appointment at Ancoats Hospital he took up general practice, and for some years had been medical officer of health for Lymm. He took the D.P.H. at Manchester in 1915. One of his sons, Dr. O. M. de Jong, was a pathologist in Manchester, and died a few years ago.

Modern Technique in Treatment.

A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions.

CXCIX.

TREATMENT OF STRANGULATED HERNIA.

STRANGULATED hernia is a variety of intestinal obstruction, which, compared with other forms, has many favourable features. Cases are seen early, and accurate diagnosis is usually possible. The site of obstruction is known, and the part of the intestine involved can often be inferred; also, from the physical character of the swelling, it is possible to form an estimate of the condition of the strangulated loop.

Inguinal, femoral, and umbilical hernia provide the great bulk of strangulations, in that order of frequency. Proportionately, however, strangulation is commoner in femoral hernia. Strangulation, which implies an interference with blood-supply, is only liable to occur where the loop of intestine passes through an aperture with rigid walls. Such an aperture is present from the commencement in femoral hernia and in most umbilical herniæ. In inguinal hernia it is of secondary formation, the result of repeated attacks of inflammation, usually at the neck of the sac. Thus inguinal strangulation arises in an old-standing hernia, and can hardly escape observation. The same process may not be discovered if it occurs in a small umbilical or femoral hernia of recent development and completely hidden by subcutaneous fat. Where symptoms of intestinal obstruction are encountered, it is therefore important to search these regions with great care. Tenderness on deep pressure above the umbilicus or in Scarpa's triangle may give the clue, even where no lump is revealed by careful palpation.

Preliminary Treatment.

Once the diagnosis of strangulation has been made, immediate operation is called for. Only when a patient is first seen when already in a condition of extreme collapse is delay justified. This condition is due to the absorption of toxic bodies, not as yet identified, from the obstructed intestine. It is strictly comparable to that of chemical shock, such as has been produced experimentally in animals by the injection of histamine or by gross damage to the tissues. The essential feature of chemical shock is that the circulatory system is starved of fluid owing to a widespread dilatation of the capillary bed; another effect of the sluggish flow in dilated capillaries is a rapid loss of heat from the limbs and body-surface.

Warmth is required to combat stasis in the peripheral circulation; if an electric cradle is not available, a liberal supply of hot-water bottles, or of blankets heated at a fire and wrapped round the trunk and limbs will serve. An effective cradle may be extemporised by placing a stove under the bed, and draping blankets on each side so that the hot air is conducted to the patient. The foot of the bed should be raised 12 inches on blocks. Fluid must be administered by rectum, by subcutaneous infusion, or directly into a vein. Since in intestinal obstruction there is probably an alkalosis in the portal circulation, 3 drachms of ammonium chloride should be added to the saline solution given by the rectum. Where shock is really severe saline solutions are useless, and a pint of 6 per cent. gum solution should be given intravenously. Solutions of gum made from commercial preparations often contain highly toxic bodies, and only those which have been physiologically tested can be given without risk.*

The Anæsthetic.

Gas and oxygen is undoubtedly the safest method of general anæsthesia for administration to collapsed patients, and in such cases is very effective. Where

* Sterile solution of gum acacia ready for use can be obtained from Evans, Lescher and Webb, 50, Bartholomew-close, E.C.1.

shock is already present spinal anæsthesia is inadmissible, owing to the rapid fall in blood pressure which may occur in the first 20 minutes after administration. However, local infiltration of the operation area with 0·75 per cent. novocaine combined with a nerve block of the ilio-inguinal and ilio-hypogastric nerves at the anterior superior spine is very effective for operations upon strangulated inguinal and femoral herniæ. Local infiltration alone works well in umbilical hernia, and is easy to carry out.

Operation.

No special incisions are required. The hernia is cut down upon, speed and hæmostasis being especially important. As the sac is distended with fluid, usually blood-stained, its identification is easy. The surrounding œdema often causes the separate coverings to stand out distinctly. The sac is opened immediately, the contents identified, and the condition of the strangulated loop inspected. The neck of the sac is then examined, and the healthy gut above and below the constriction is pulled down into the wound. Rarely it is necessary to incise the neck of the sac from within by a hernia bistoury, in order to release the constricting band. Such a procedure is difficult, and there is the double risk of wounding the gut and cutting an artery near the neck of the sac.

In an inguinal hernia division of the various layers nearly always releases the constriction; if not, the sac should be laid open in its length till the imprisoned loop is released. In an umbilical hernia the constricting ring can be cut freely outside the peritoneum. It is in femoral herniæ that difficulty is most commonly met with. The constricting element is not usually Gimbernat's ligament, as H. S. Souttar has pointed out, but a fibrous ring in the sac wall itself. Should it be impossible to pull the gut down with gentle traction, it is best to open the inguinal canal and divide Poupart's ligament, so that the neck of the sac can be freely laid open. Where there is a tight constriction and a probability that a portion of gut may have undergone pressure necrosis, this should be done at once. The attempt to pull such a loop either up into the abdomen or down into the sac in either case carries with it the risk of soiling the peritoneum with fæcal contents. The safe thing is to lay the doubtful gut bare and proceed according to what is found.

The loop of the gut when inspected is either obviously viable, obviously dead, or doubtful. When it is obviously viable, it is returned to the abdomen; when it is obviously dead, the gangrenous loop must be removed; the gut above and below may be joined end to end, or a tube may be tied into each portion, to drain away the intestinal contents, the continuity of the alimentary canal being restored by a second operation, usually 48 hours later. If the general condition of the patient is poor, and the condition of the bowel above the obstruction bad, drainage is to be preferred. If not, an entero-anastomosis should be carried out. The latter allows satisfactory repair of the hernia. Drainage implies healing by granulation, and the need for some form of permanent truss after recovery.

Where the gut is doubtful it is wrapped in a large abdominal swab wrung out in saline solution at 120° F. and left for five minutes, when it is nearly always possible to decide on the recuperative power of the wall.

Its consistency is of more importance than its colour or its lustre. If after the application of warmth and moisture it remains soft and flabby like wet blotting-paper, it will not survive. If death seems probable, resection should be carried out. A linear band of discoloration remaining where the constriction ring actually compressed the intestine and not involving its whole circumference, may, however, be infolded with a continuous stitch, and resection avoided. A patch graft of omentum may be sutured over the infolded line to insure against leakage in the event of necrosis.

If recovery seems likely, the loop may be returned to the abdomen, the hernial orifice repaired, and through a separate stab wound a small rubber tube led down to the doubtful loop. Such a portion of intestine will remain close to the hernial orifice, for it will not undergo peristalsis and the damaged surface will adhere to the neighbouring peritoneum. Should part of the wall give way in the ensuing week, the drainage-tube ensures that the general peritoneal cavity will not be infected, but that the contents will be led to the surface. As soon as the patient's condition justifies a further operation, the resulting fæcal fistula is closed by resection of the damaged portion.

Unless intestinal drainage has been necessary, the hernial aperture should be repaired and the wound closed with great care.

Post-operative Treatment and Prognosis.

While the operation is a local problem, the post-operative treatment is that for any form of intestinal obstruction. The form it shall take and the prognosis that can be offered depend entirely on the degree of toxæmia of the patient, and the amount of distension and of interference with the neuro-muscular mechanism of the wall of the gut. Should the obstruction be relieved by early operation after-treatment will usually give no anxiety. If toxic absorption has manifested itself, the measures outlined above should be prosecuted with vigour.

The intestinal wall requires the same treatment as any other weak or paralysed muscle. The principles are those employed in the re-education of a limb affected by poliomyelitis, modified to suit the case of a hollow muscular tube. They are, rest in a position of relaxation, the encouragement of nutrition, warmth, and avoidance of meddlesome stimulation.

Relaxation and rest are obtained by emptying as far as possible the distended proximal part of the alimentary canal and by withholding food and fluids by mouth, so that the weakened portion shall not be called upon to pass anything down, until decreasing distension and the passage of contents per rectum demonstrate that the contractile power has recovered. If much distension of the loop above the strangulation is present at the time of operation, its contents may be partially emptied either by puncture with a trocar, or, if resection is necessary, by passing a tube into the lumen. If the distension affects the upper part of the small intestine, a valvular jejunostomy is indicated. The stomach should be washed out both before and at the end of the operation in all cases showing intestinal distension. If fæcal vomiting has been present, a Ryle gastric tube may be passed down one of the nostrils into the stomach, and the gastric contents evacuated at short intervals by a Sprengel's pump.

As only sips of water may be given by mouth, fluids must be given plentifully by other means. Glucose should be added to fluids administered by the rectum or intravenously in the proportion of 6 per cent. Warmth, in the form of large fomentations of gamgee tissue applied at frequent intervals to the whole abdomen, is of real service.

Drugs.

Drugs are of very little value, and may be harmful. In strangulated hernia the practitioner is fortunate in having to deal with a healthy body, temporarily thrown out of gear.

We should help the intestinal wall in its efforts to propel contents along the lumen, but never try to make it do so. A series of gentle pushes may succeed where a vigorous kick only does harm. Aperients, one and all, act as irritants, and should never be given; they not only flog a muscle which is doing its best, but also cause an outpouring of fluid into the lumen. Irritants are already present in the form of toxic intestinal contents. Eserine applies an uncontrolled stimulus through the motor nerve to the muscle, and its use is therefore wrong in principle. A safer stimulant to peristalsis is the reflex one set up by the administration of a turpentine enema. Pituitrin acts directly on the muscle and is less harmful, but even so is better withheld, unless it is obvious that the natural powers of recovery are insufficient. Then it may be given in ½ c.cm. doses every two hours.

A valuable expedient is to run half a pint of liquid paraffin warmed to 100° F. down the stomach-tube, after washing out the stomach. This is entirely inert, and will neither stimulate an exhausted musculature to unavailing efforts, nor provide food for bacterial multiplication, but it has a marvellous power of finding its way along the canal, and re-establishing the normal passage of contents.

Taxis.

If a hernia is merely irreducible and there is neither tenderness in the swelling nor any sign of intestinal obstruction, taxis may be attempted. At a later period it is only justifiable if the condition of the patient or the absence of facilities make operation out of the question. When the swelling is dull to percussion any rough handling is dangerous.

Assistant Surgeon, Guy's Hospital.

Special Articles.

THE RELATIVE INFLUENCE OF FOG AND LOW TEMPERATURE ON THE MORTALITY FROM RESPIRATORY DISEASE.

BY W. T. RUSSELL.

(From the Statistical Department, National Institute for Medical Research.)

IN a paper published in THE LANCET[1] I examined the influence of fog and temperature on the weekly mortality from respiratory disease among children and adults during the winter months, October to March, in the Metropolitan boroughs of Islington and St. Pancras over a period of 21 years, beginning at 1870. The analysis was made chiefly by graphical methods and the following conclusions arrived at.

1. That fog itself has no appreciable effect on the respiratory death-rate.

2. That if the prevalence of fog is associated with a low temperature and frost the respiratory death-rate of adults can be influenced very considerably, although no such effect is evident in the case of children.

Method of Partial Correlation.

When the foregoing was written, I had in mind the fact that the method of partial correlation would have carried the analysis a stage further and demonstrated which of the two variables, a fall in temperature or the presence of fog, exercised the greater influence on the respiratory mortality. I refrained from the application of this method at the time, however, as one of the variables, the amount of fog, could not be regarded, in a statistical sense, as forming a normal distribution. Since then Dr. Major Greenwood has suggested that, in the absence of a more suitable mathematical formula, the method of partial correlation would give an answer having at least some value as a first approximation and, in investigating the subject in this way, I am indebted to him for much valuable advice. I have calculated, in addition to the means of the three variables and the standard deviations of their distributions, the essential correlation coefficients and regression equations between the number of respiratory deaths among adults at ages 55 and upwards in the following week and (1) the mean temperature of the previous week, (2) the amount of fog in the previous week. A lag of one week in the deaths was allowed for in view of the fact that Dr. Greenwood, in an unpublished research to which he kindly gave me access, had found that the temperature was more highly correlated with the death-rate in the succeeding week than with that in the same week. Although the correlation coefficients were calculated for the corresponding week over the series of 21 years for each of the 26 weeks, comprising the period October to March, the tabular presentation and discussion are limited to the interval between the eleventh and nineteenth week, as the greatest prevalence of fog occurred, on the average, during this period. As regards the amount of fog, the assessment was made on a purely arbitrary basis. Where it was stated in the weather records that fog prevailed at 9 A.M. and at 9 P.M., and the explanatory note indicated that fog was present throughout the day, the amount of fog for that particular day was represented by 100. Fog in the morning and lasting until noon was standardised as 50, and so with intermediate amounts, due regard being given to duration and intensity. A series of comparative figures of the daily amount of fog were thus obtained. The totals for the days in each week were summed and the results taken as representing a quantitative statement of the weekly incidence of fog. Objection may possibly be raised to this system of measuring fog in order to ascertain if any association exists between its prevalence and an increase in the respiratory death-rate, as the effect of two successive foggy days might exercise a more deleterious effect on the respiratory organs than would the presence of fog on four successive half days, and yet the total amount of fog for the two weeks would be quantitatively the same. In the present case the data were not sufficient to consider periods shorter than a week. But a like criticism can be directed against the use of the mean temperature as officially published, the influence of two very cold days in any one week of otherwise high temperature can be overshadowed in the statement of the mean temperature for the week.

[1] THE LANCET, 1924, ii., 335.

The Results Examined.

The results now fall to be examined. During the period the eleventh to the nineteenth week of the 21 years there was no great variation in the average weekly temperature, as will be observed from Table I. The lowest mean temperature, 37·8° F., occurred in the fifteenth week, and the highest, 40°, in the nineteenth week. The standard deviations showed that the temperature distribution was much the same for each of the nine weeks as the values ranged from a minimum of 4·57° to a maximum of 6·27°. With the exception of a few weeks the mortality, like the temperature, was fairly constant. The greatest number of deaths occurred, on the average, in the nineteenth week, when there were 41 deaths. The next highest totals were 38 and 37 in the fourteenth and fifteenth weeks respectively. Apart from the nineteenth week, when the standard deviation reached 28·63 as compared with 16, the average for all the weeks, there was little dissimilarity in the distribution of the deaths. As regards the amount of fog, with the exception of the eleventh week over the series of years when the mean was 163, the other weeks seemed to be characterised by a general constancy in the average which centred round 80. But this similarity in the magnitude of the means must not be accepted as implying a like similarity in the distributions. There was a wide variation in the amount occurring in the particular weeks of certain years as the standard deviations of the distributions ranged from 66 to 135.

Having seen the manner in which the magnitude of the three factors varied, it was next of interest to study their interdependence as measured by the size of their correlation coefficients of the zero and first orders given in Table II. As was to be expected, the correlation coefficients between temperature and the number of respiratory deaths were negative in sign, and, in the present case, were all statistically significant, as they exceeded twice their standard errors. The highest coefficient of the zero order occurred in the thirteenth week of the 21 years, when the value was $-0{\cdot}806 \pm 0{\cdot}076$, and the two smallest $-0{\cdot}381 \pm 0{\cdot}187$ and $-0{\cdot}459 \pm 0{\cdot}172$ were found in the twelfth and nineteenth weeks respectively. The mean value of the coefficient for the series of nine weeks was in the neighbourhood of $-0{\cdot}54 \pm 0{\cdot}14$. The amount of fog and the number of deaths were positively correlated and in the eleventh week the value was $+0{\cdot}553 \pm 0{\cdot}151$, in the twelfth week $+0{\cdot}542 \pm 0{\cdot}151$, in the fourteenth week $+0{\cdot}777 \pm 0{\cdot}086$, in the eighteenth week $+0{\cdot}855 \pm 0{\cdot}059$, and in the nineteenth week $+0{\cdot}569 \pm 0{\cdot}086$. The correlation coefficient of $+0{\cdot}855 \pm 0{\cdot}059$ between the amount of fog in the eighteenth week and the respiratory deaths in the nineteenth week was remarkably high, and some of its importance was due to the size of one pair of coördinates—namely, the temperature and the amount of fog in the fourth week of 1880, which was the eighteenth week of the series as reckoned from the beginning of October of the previous year, and the respiratory deaths in the nineteenth week—i.e., the week ending Feb. 7th, 1880. In this instance the mean temperature was 28·9°, the amount of

1 = Number of deaths. 2 = Temperature. 3 = Amount of fog.

fog 345, and the number of respiratory deaths 156. This excessive mortality was real and was not due to any error of deferred registration of deaths as the weekly returns of the Registrar-General's Department for the week ending Feb. 7th, 1880, contained the following statements regarding the mortality for London generally.

"The annual death-rate from all causes which had been equal to 24·6, 27·1, and 31·3 in the three preceding weeks, further rose last week to 48·1 per 1000. The death-rate last week, under the influence of cold and fog, was higher than it has been in any week since the cholera epidemics of 1849, 1854, and 1866. The largest proportional excess of deaths last week occurred among persons aged upwards of 60 years. The deaths referred to diseases of the respiratory organs which had been 559 and 757 in the two preceding weeks, further rose to 1557 last week and exceeded the corrected weekly average by no less than 1118."

The importance of the high correlation in the week mentioned will be referred to later. The average coefficient between the number of deaths and the amount of fog for the nine weeks was $r = + 0{\cdot}434 \pm 0{\cdot}177$. When the partial correlation coefficients were calculated so as to exclude the influence of the one factor when the other was correlated with the number of deaths, the values were reduced in magnitude, but seven of the nine coefficients between the temperature and the deaths with the amount of fog constant remained sensible, and four in the case of the fog and the number of deaths with the temperature constant. It will be observed that in the thirteenth week, the sign of the partial coefficient between the amount of fog and the number of deaths became negative. An examination of the original weather records for this week over the series of 21 years revealed a curious anomaly, that in one instance the week ending Dec. 27th, 1879, the presence of fog and a low temperature produced no effect on the death-rate, as is indicated by the following statement of the daily records of temperature and fog in this week and the mortality of the succeeding weeks.

Record of Temperature, Fog, and Mortality for Week ending Dec. 27th, 1879.

Days in week ending Dec. 27th, 1879.	Mean temp.	Remarks.	Weeks ending—	No. of respiratory deaths.
21st	31·0	Sharp frost in morning. More or less fog all day.	Dec. 20th	41
22nd	29·2	Fog in the evening, very dense from 9 P.M.	,, 27th	46
23rd	34·9	Slight fog all day, thick fog at night.	Jan. 3rd	32
24th	31·9	—	,, 10th	21
25th	31·5	Dense fog clearing after 8 P.M.	—	—
26th	32·6	—	—	—
27th	30·0	—	—	—

In five of the series of nine weeks the partial correlation coefficients between the temperature and the number of deaths with the amount of fog constant were in excess of those between the amount of fog and the mortality with the temperature constant, and in the remaining instances the higher value was between the mortality and fogginess. When the average partial coefficient was calculated for the nine weeks over the series of the 21 years the value was $- 0{\cdot}533 \pm 0{\cdot}156$ when the amount of fog was constant and $+ 0{\cdot}324 \pm 0{\cdot}195$ when the effects of temperature were eliminated. The latter value does not exceed twice the size of its standard error and, therefore, cannot be considered as statistically significant. These results thus show that, although fog had a decided influence in some weeks, yet, on the average, a low temperature exercised the more dominant influence.

Accuracy of Prediction.

Having seen the degree of relationship that existed between the weather factors and the number of respiratory deaths, it now remained to be seen to what degree of accuracy the number of deaths in

any one week could be predicted if the temperature and the amount of fog in the previous week were known and what error was involved if the forecast was made from temperature alone. To find a solution to these problems, two regression equations were calculated for each week: (1) the one, a multiple regression, between the deaths on the one hand and the temperature and the amount of fog on the other; (2) the other, a simple regression, between the deaths and the temperature alone. By means of these equations, the numbers of weekly deaths were predicted from the amounts of fog and temperature and the percentage mean error between the theoretical and observed values were calculated. The results are given in Table III., where it will be seen that, in six

D = Number of respiratory deaths.
T = Mean temperature. F = Amount of fog.

out of the series of nine weeks, the forecast based on the temperature alone was practically as good as that founded on the combined effect of temperature and fog as the percentage mean errors in both instances were almost identical. As might be expected, in the weeks in which the correlation coefficients between the amount of fog and the mortality exceeded those between the temperature and the deaths, the errors derived from the multiple regression were less than those resulting from the simple regression. The greatest difference occurred in the nineteenth week of the series of years in which the errors were 25·44 and 34·85 per cent. respectively. Reference has already been made to the fact that in London generally there was an exceptionally high respiratory mortality among the adults in the corresponding week in the year 1880, which the Registrar-General connected with the "low temperature and dense fogs." In the same week of that year in Islington and St. Pancras the respiratory deaths among adults numbered 156, the theoretical number deduced from the influence of temperature alone was 84, but when the combined effect of fog and temperature were taken into consideration the number of deaths was raised to 131. The impression conveyed by Table III., that even if the measure of fog and temperature in one week is known it is impossible to predict very accurately the number of deaths from respiratory disease in the following week, is, of course, correct. Thus in the series giving the least percentage error (that for the fourteenth week), on the average there is an error of the order of one-fifth of the average value and the individual discrepancies between observations and predictions are often large. For instance, in the year 1890 there were actually 86 deaths in the fourteenth week, the calculation from fog and temperature provides only 61; in 1886 there was also heavy mortality, 74; the calculation only postulates 51. But that this method of calculation is nearer the truth than if the effects of temperature and fog of the previous week are ignored may be easily proved. If there is an unknown series of numbers written on tickets and a person is asked to guess the number written on one ticket drawn at random, what shall he guess? If he knows nothing whatever about the numbers, any guess is as good as another and is a mere guess. In public health problems further particulars are usually available. If one is asked what is the most probable number of deaths in a particular week of the year, it would seem reasonable to say the average number of deaths in that week (corrected for changes of population) over a series of years, when the deaths dealt with are due to a cause not known to be increasing or diminishing. But if that system were adopted in the case just mentioned the estimate would be 38 deaths for both 1886 and 1890; the calculation gives 61 and 51 respectively and, although not good approximations to 86 and 74, are still very much nearer the true value than 38 and 38. In fact, as a little calculation, which it seems unnecessary to reproduce in full, shows, if a knowledge of the temperature and fog in the previous week is made use of, the average accuracy of the prediction is improved to the extent of 34 per cent. of its measure of uncertainty, that under the most favourable circumstances predicting from the mean value would give an average percentage error not of 20 but of 30. For these reasons these regression equations have, I think, some little practical value. I should, however, strongly deprecate any suggestion that by their means it is possible sharply to distinguish the respective shares of fog and low temperature in the genesis of mortality.

Conclusion.

It is essential to bear in mind that, in any study of the influence of weather on the prevalence of disease, the assignment of the increased mortality to any particular factor is not nearly so simple as is generally believed. The fact, often overlooked, is that there are a multiplicity of causes, both atmospheric and meteorological, all of which are highly inter-related, and it is the cumulative effect of these, and not the influence of an individual factor that finds expression in an increased death-rate from respiratory disease. The same point is strongly emphasised by Sir George Newman in the annual report of the Ministry of Health for 1925, p. 27, in the following sentence:—

"The true inference is, I believe, that in the matter of atmospheric pollution, as in that of meteorological factors, the inter-related variables in any given case are so numerous that only by means of a far longer series of observations than our data provide can any valuable statistical conclusions be reached."

As regards the importance of the two factors examined, temperature and the amount of fog, so far as the present data are concerned, it seems warrantable to conclude:—

1. That although the number of respiratory deaths in the following week was more highly correlated with the fogginess than with the temperature of the previous week over certain periods, yet, on the average, a low temperature exercised the greater influence.

2. That knowing the temperature and the amount of fog, it is possible to predict the mortality of the succeeding week, but only within a marginal error of roughly 30 per cent.

THE LATE DR. H. D. CROOK.—Dr. Herbert David Crook, who died suddenly on Nov. 15th at the age of 70, received his medical education at Bristol and Leeds, and qualified as M.R.C.S. in 1877. He served as surgeon-major in the Turkish Army during the Russo-Turkish War of 1877–78, and became medical officer in Constantinople; soon afterwards he acted as surgeon to the Field Force in Griqualand, South Africa. In 1901 Dr. Crook settled in Kimberley, but later left for Canada where he interested himself in farming. Five years ago he went to Irchester, Northamptonshire, and took up the practice in which he was engaged at the time of his death. He leaves a widow, two daughters, and a son.

THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

THE annual meeting of Fellows and Members of the College was held on Thursday, Nov. 18th, at the College in Lincoln's Inn-fields, Sir BERKELEY MOYNIHAN, the new President, in the chair.

The report of the Council stated that during the past year a deputation had been received from the Association of Members urging that in the petition of the College for a new Supplementary Charter, which was granted in August last, there should be included a clause securing for Members representation on the Council. Such a clause, according to the report, was not included because of its controversial nature.

The PRESIDENT explained the significance of the new Supplementary Charter, which gave the Council power to alter by-laws in accordance with a long and careful method of procedure; certain by-laws, he said, had already passed the stages of revision, the intention being that they would come into force early next year. Only once, he added, had the annual addition to the number of Members been larger than it was during the year under consideration, when the figure 768 was reached.

Mr. H. WANSEY BAYLY moved a resolution that this meeting should reaffirm the justice of admitting Members to representation upon the Council, and should urge the Council to submit the matter to a postal vote of Fellows and Members. Dr. REDMOND ROCHE seconded the motion, pointing out that it was sought in this way to remedy the injustice to the general constituency of the College brought about by the Charter of 1843, which vested the government of the College in the Fellows. The resolution was carried by a large majority.

CRIPPLED AND INVALID CHILDREN.

LONDON CONFERENCE, NOV. 18TH–19TH, 1926.

A CONFERENCE on the Care of Crippled and Invalid Children, arranged by the Invalid Children's Aid Association and the Central Committee for the Care of Cripples was held in the Great Hall of the British Medical Association on Nov. 18th and 19th. The chairmen at the four sessions were Lord Islington, the Duchess of Atholl, Sir Arthur Stanley, and Sir Robert Jones, and the opening address was delivered by Lord Eustace Percy in the absence of the Minister of Health, who was engaged, as Mrs. Neville Chamberlain explained, in presiding over the Standing Committee dealing with a Bill on smoke abatement.

A Survey of Work in Progress.

Mr. R. C. ELMSLIE reminded the audience that the prevention of crippling conditions was not easy. Much more knowledge was needed of infantile paralysis —now the greatest cause of crippling—before it could be prevented. Tuberculosis was diminishing and did yield to adequate social improvement, but the exposure of the child to infection from parents and others could only be got over gradually by preventive measures and education. Provision for the treatment of rickets would be needed for many years; the congenital causes of crippling in this country were at present unpreventable.

Sir ROBERT JONES said there was great ignorance of the causes of tuberculosis and rickets. Parents did not know that every tuberculous child had become infected by the ingestion of the bacillus either from milk or by direct contact with a human consumptive, and they generally looked upon rickets as a hereditary scourge from which there was no escape. The essential duties of the C.C.C.C. were medical rather than educational, and they must aim at cutting off the supply of cripples at the source. There were very few facilities for cripples over school age; some of the dismantled Poor-law infirmaries might be equipped to deal with these patients.

Dr. R. VEITCH CLARK said that, as M.O.H. of Manchester, he received about 500 notifications each year of new cases of tuberculosis in children under 15 years of age, of which at least half were non-pulmonary. A milk-supply 10 per cent. of which was tuberculous was a scandal. The relation between catarrhal conditions and rickets was not realised, nor was the importance of fresh air and sunlight in combating it understood. Inadequate diet was a corollary of poverty and would always be with us to some extent, but the abolition of atmospheric pollution was within our power and, if carried out, would, he believed, practically eliminate rickets.

The Preventive Side.

Papers on Rickets, Rheumatism, Chorea and Heart Disease, and Tuberculosis were read respectively by Dr. Stuart J. Cowell, Dr. Arbour Stevens, and Dame Agnes Hunt.

Dr. COWELL said that rickets was commonly thought of as a disease of children's bones, producing lameness. Actually, however, it caused also disturbance in the general processes of the body, and was responsible for teeth that developed late, for flabby muscles, reduced resistance to disease, and a disposition to languor and apathy. The antirachitic vitamin (D) could be manufactured by exposure to ultra-violet light, and many foods—milk, fats, oils, and vegetables which contained little or none of the vitamin—could be rendered powerfully antirachitic by exposure to ultra-violet rays. Rickets could be prevented either by an adequate supply of vitamin D in the food or by exposing the body to ultra-violet light. A mother could hand on her supply to her developing offspring both before birth and during lactation. A widespread use of cod-liver oil by mothers would do a great deal to reduce rickets, and small doses of a quarter of a teaspoonful twice a day could safely be given to an infant of a few days' old. Cow's milk varied in vitamin capacity, the pasture-fed summer cow giving milk with a high antirachitic vitamin content, and the stall-fed winter cow practically none. It might be feasible to give the cows ultra-violet light treatment in winter. To prevent the crippling effects of rickets we must rely on early treatment, and it should be remembered that nature would work wonders if given the opportunity. The assertion that rickets was now rare in London was hardly borne out by recent statistics, and it was still rampant in industrial centres.

Dr. STEVENS pleaded for the treatment of cardiac cripples alongside orthopædic cripples. They needed the same things—early treatment, more hospital beds, specialists to treat them, prolonged stay in hospital, and intelligent after-care. There were some 80,000 to 100,000 cardiac cripples in the country, for whom little was being done. Heart disease in children was increasing, these cases now outnumbering those suffering from tuberculosis. Views varied greatly as to the cause of heart disease. Poverty was recognised as a predisposing, though not as a primary cause, but Dr. Stevens considered that the poor, who could not afford proper nourishment or good housing conditions, were the greatest victims, and that malnutrition was the chief predisposing cause. There was a definitely acid type of child, whose diet was lacking in such articles as milk, eggs, and cheese, and an enormous proportion of heart disease cases occurred among this group of children.

Dame AGNES HUNT thought it extremely difficult to prevent tuberculosis because it took so long to manifest itself. A consumptive mother might suckle her new-born infant, kiss it, and sleep with it, and it was almost impossible to take preventive measures with a baby of 4 or 5 months old. In any case, it was not fair to place the burden of prevention on a sick and overworked mother. Trouble should be taken to spread a knowledge of the laws of health, and to combat ignorance, vice, and dirt.

"Unity of Effort."

Dr. C. E. TANGYE gave an outline of the orthopædic scheme in Wiltshire, linked up with that for Bath and the county of Somerset. The scheme was run by a

purely voluntary committee, but the county council was its backbone as far as finance was concerned. Coöperation from general practitioners was an essential part of the scheme, and doctors were beginning to refer their patients from the earliest stages. The spectacular appeal would gradually disappear as prevention became more and more the aim of all orthopædic schemes. Dr. Tangye blamed old-fashioned desks and forms in schools for many postural deformities, and said that the provision of furniture which did not manufacture crooked spines should be considered an elementary duty of any local education authority.

Mr. G. R. GIRDLESTONE spoke on the part of voluntary effort in an orthopædic scheme, and made out a strong case for the voluntary hospital and for a scheme worked out on a voluntary basis. One great objection to a purely official hospital dealing with cripples was the age limit. In a hospital run by a local authority no treatment could be given to any of these patients over school age except those suffering from tuberculosis. Many victims of infantile paralysis and of accidents, and others were thus unprovided for, and no system should be accepted which excluded them. A hospital could not be run entirely on a voluntary basis without financial help from the local authority, but he preferred the partly voluntary type and a staff that was honorary or paid on a part-time basis. Members of such a staff often held special orthopædic appointments, and this encouraged coöperation between special and general hospitals. Patients came to a voluntary hospital or clinic through all sorts of channels, official and private. If the clinic was run by a voluntary committee it soon became widely known locally, and cases tended to come at an earlier stage. Where local authorities tried to run clinics with their own personnel, without the help of skilled and semi-skilled volunteers, the staff got grossly overworked.

Dr. W. G. SAVAGE explained what he considered a more excellent way. In Somerset the orthopædic scheme was administered by the county council, use being made of the voluntary hospitals. Instead of waiting till public sympathy was aroused to start a clinic, this was done by a stroke of the pen, the clinics being run by the county council in its own premises. Voluntary help was taken advantage of, but it was under the control of the local authority. By this arrangement there was better selection of cases. He did not think the age limit a disadvantage. When resources were restricted it was necessary to be a little hard-hearted, and to concentrate on the cases likely to give the best results. Unless prevention was in the forefront it was not worth carrying on a scheme at all. The curative side was in the very bones of the staff of a voluntary hospital, and they were not accustomed to doing preventive work.

Mr. GIRDLESTONE said, in reply, that time would prove which method was the best, and that method would be adopted, but different systems might apply in different areas. He would remind Dr. Savage that any orthopædic scheme existed only because up to the present prevention had not been successful. Official channels were just as ready to pass children quickly to the clinics whether the clinics were official or voluntary in origin. The real economy was to secure early diagnosis and treatment, and voluntary hospitals did take an interest in preventive work.

Dr. W. B. KNOBEL said that London had a complete scheme for children suffering from tuberculosis, and no child recommended for residential treatment was ever kept waiting. But they could not get the cases early. Children were sent to hospital schools after they had been attending for weeks, months, or even years, at out-patient departments. Nobody could really think it better for a child with a tuberculous hip or spine to be treated at an out-patient department than in a country institution. There was said to be a shortage of beds for infantile paralysis. But there were plenty of beds in the fever hospitals of the M.A.B. for cases in the first stage, and the 50 beds at Carshalton for the second stage were never full. He pleaded with orthopædic surgeons to place children in the best conditions at the earliest moment.

Sir ARTHUR STANLEY expressed some disappointment that the hopeful signs of a scrap between Mr. Girdleston and Dr. Savage had petered out so amicably. Personally he thought the best plan was an official scheme supplemented by voluntary effort.

Education of the Cripple.

At the final session of the Conference the education of the physically defective child was discussed from the point of view of the surgeon (Mr. K. J. Acton-Davis), of the school manager (Mrs. Salmond), of the matron (Miss Hughes), and of the teacher (Miss James). Sir Montagu Burrows dealt with the subject of the physically defective child after school, and there was some useful discussion on the vocational training and placing of cripples in employment.

THE MECHANISM AND INCIDENCE OF INDUSTRIAL LEAD POISONING.

IT is important to realise that the chief danger in any lead trade results from inhalation of dust or fumes; thus the painter using ready-mixed paint incurs only the very slight danger of ingesting small amounts of lead—e.g., from his paint-smeared fingers. As soon, however, as he uses sandpaper on painted surfaces by any *dry* process, he begins to inhale large amounts of lead dust and he inhales oxides of lead when he burns paint from a painted surface with a blow-pipe. Animal experiments (T. Oliver, 1914, and J. C. Aub, 1924) have demonstrated that *inhalation* of small amounts of insoluble lead compounds is much more dangerous than *ingestion* of very large amounts.

Work in Germany (Gusserow, 1861, Heubel, 1871) and in U.S.A. (Aub, 1924) has shown that inhaled and ingested lead compounds are stored as an insoluble phosphate in the skeleton. This may be gradually mobilised and excreted in the ordinary course of metabolism, or by the ingestion of acids; in passing through the blood-stream it produces toxic symptoms. Detailed analyses of human tissues have shown that workers in dusty lead trades may have from 0·5 to 1 g. of lead phosphate in the skeleton.

Susceptibility of Women.

In a discussion whether women are more susceptible to lead poisoning than men, Alice Hamilton (Harvard), in her book "Industrial Poisons in the United States," quotes the following facts:—

The White Lead Works, Newcastle-on-Tyne, in 1897 employed 328 men and 571 women. During six months of that year 19 men were reported as having lead poisoning, a rate of onef or every 17 employed; and 66 women or one for every eight to nine employed—i.e., the rate was just double (Oliver).

The report of the Factory Inspection Department for 1910 showed that in the Staffordshire potteries there was twice as high a rate of plumbism among women dippers as among men dippers.

Newman, McConnell, Spencer, and Phillips, of the United States Health Service in 1921 examined 1436 men and 373 women (Occurrence of Lead Poisoning in the Pottery Trades of New Jersey, Pennsylvania and Ohio). Although the men were far more exposed to lead in this trade than women, there was more plumbism among the women than among the men. The average length of exposure of the "positive" male cases was 17 years, and the female cases 9·3 years.

It appears that the female reaches certain stages of lead poisoning in about half the time required for the male to reach them. In one series, comparing the men and women who work side by side in the dipping rooms, it was found that 58 male ware-carriers had no positive cases of plumbism, whilst 62 women doing the same work had a rate of 4·8 per cent. Among 71 male dippers' helpers the rate of plumbism was 8·4 per cent., and among 149 female dippers' helpers the rate was 14·4 per cent. In one series of

Hamilton's, however, and in another observation of Prendergast's and in another of E. Collis's, there was no numerical difference between the incidence in men and that in women.

E. L. Collis and M. Greenwood (" The Health of the Industrial Worker," 1921) sum up the subject as follows :—

> The statement is not infrequently made in relation to lead poisoning that females exhibit a sexual proclivity to plumbism. We hold that the effects of plumbism in causing miscarriage and still-birth is a sufficient reason for excluding females from exposure to lead dust, but we do not feel satisfied that there is evidence that they fall victims more readily than men. When women (who by long employment had become more or less acclimatised, more or less immune to the influence of lead) were quite wisely prohibited from work in white lead beds in 1897, and their place was taken by non-acclimatised men, a great rise in cases of plumbism occurred affecting the men. Later, as the causation—the inhalation of lead dust—became more fully recognised and guarded against, the case-incidence fell almost to vanishing point. When, 20 years later, during the war, owing to the scarcity of male labour, the employment of women at this work was again permitted temporarily and non-acclimatised women took the place of acclimatised men, no rise in the case-incidence occurred. It was confidently expected that a rise would occur because the new workers were non-acclimatised, and not because they were women ; and the absence of any significant rise was at once attributed to the efficacy of the precautionary measures now adopted and to the resistant powers of woman. On the completion of the war the men resumed their old work ; during the period of war service they had lost their acquired immunity ; more cases of poisoning were now reported among the men than occurred when the women took over the work. The existence of greater activity in the industry in the post-war period must be remembered when considering this evidence; but after due allowance has been made it supports the view that women are not more susceptible to lead poisoning than men. We are unaware of any scientific evidence in support of the alleged sexual proclivity and regret that a case, sound in itself, should be supported by unsound arguments.

Thus, in weighing the figures quoted it is necessary to take the economic factor into consideration, for, apparently, when men and women were under equally unfavourable economic conditions the incidence was the same. It may be argued that the older figures show a greater incidence amongst women, because of the inferior economic conditions under which they had to exist. The average exposure of the women, however, is much less (see figures of United States Public Health Service by Newman and others quoted above).

Damaging Effects in Women.

Lead seems to do more harm to women than to men. They succumb in shorter period (Hamilton, quoted above). They also get more severe forms of poisoning, especially convulsons and blindness. Prendergast, 1910, in the Potteries, found the following :—

640 Cases.

	Men. %	Women. %
Colic	77·6	69.1
Paralysis	57·0	30·0
Lead convulsions	15·0	34·9
Total blindness	2·3	7·7
Partial blindness	3·5	10·2

Hamilton discovered the greater liability of women to lead encephalopathy in the United States pottery industry. In 1911 there were 1100 men employed in lead processes in the potteries and 87 cases of lead poisoning had occurred among them during that year—a rate of about 8 per cent. During the same year there were 57 cases among the 393 women employed—a rate of 14 per cent. The proportion of encephalopathy in the male cases was only 1 in 17 ; in the female cases it was 1 in 4·5. These figures, of course, refer to white lead dust, but all authorities are agreed that the painting trade is a frequent source of the worst forms of lead poisoning.

Oliver states that the maximum age-incidence occurs at an earlier age in women (18–23) than in men. Further, this is the age when they would be employed in painting. Oliver further says that while females rapidly break down in health under the influence of lead, men can work a longer time in the factory without suffering, their resistance apparently being greater.

Reproduction.

The work of the Harvard group (Aub and collaborators, 1922–1926) shows that lead absorbed is stored in the bones and may at any future time become free in the circulation. Women exposed to lead before marriage, therefore, run the risk, when married, that, even though they are now removed from exposure, they may have miscarriages and dead babies because lead can be liberated from the bones and destroy the ovum or fœtus. Reid gives the following figures :—

100 Mothers.

Occupation.	Miscarriages and stillbirths.	Deaths under one year per 1000 born.
Housework	43·2	150
Mill work, not lead	47·6	214
Lead work before marriage	86·0	157
Lead work after marriage	135·5	271

This table shows that mill work after marriage, even without exposure to lead, results in a high rate of infant mortality ; but lead work before marriage increases the abortion-rate. Lead work after marriage shows both these effects to an exaggerated degree.

Dineufbourg wrote a thesis in 1905 on the effects of parental plumbism. He divided the cases into three groups : (1) Women married to lead workers, but themselves free from lead ; (2) women who had been exposed, but married men free from lead ; (3) women who had been exposed who married exposed men.

—	Pregnancies.	Abortion.	Stillborn.	Per cent.	Born living.	Percentage of living surviving first year.
Fathers leaded	442	66	47	25·5	329	74·4
Mothers leaded	134	17	6	17·0	111	73·9
Both parents leaded	23	4	4	35·0	15	66·6

It is, of course, in the third group that the effect of the lead is most striking. If the two other groups are compared, paternal plumbism seems to be as disastrous as maternal plumbism, and, indeed, the abortion-rate is actually higher ; but the second and third groups are too small to be taken very seriously. A. Pinard quotes a case of a woman, married to a lead-poisoned man, who was pregnant five times and always prematurely delivered of a dead child and who then bore to a healthy man a perfectly normal child.

Cole, of Wisconsin, and Weller, of Michigan, fed commercial white lead in capsules to guinea-pigs with the following results :—

—	Free female mated with :	
	Free male.	Lead male.
Number of offspring	58·0	65·0
Average birth-weight, grams.	81·5	66·3
Number still-born	3·0	3·0
Died first week	2·0	9·0

RHEUMATISM AND HEART DISEASE IN CHILDREN.—An anonymous lady has given £12,000 to the Children's Home Hospital, Strathblane, Stirlingshire, to equip and partially endow a home for children recovering from rheumatism and resultant affections of the heart. The home will be the first of its kind in Scotland, and Dr. Leonard Findlay is to be consulting physician.

TUBERCULOSIS WEEK-END CONFERENCE.

LONDON, NOV. 19TH–22ND, 1926.

THE first meeting of a Conference arranged by the Tuberculosis Society and the Superintendents of Tuberculosis Institutions was held at the House of the Royal Society of Medicine on Friday, Nov. 19th, under the chairmanship of Dr. JAMES WATT, when Dr. O. STRANDBERG, of the Finsen Institute, Copenhagen, read a paper on

Heliotherapy and Artificial Sunlight

in the Treatment of Tuberculosis, and particularly Tuberculosis of the Larynx. Speaking in fluent English, Dr. Strandberg stated that the midday sun in the southern Alps and lowlands and in Switzerland contained the healing rays in their most active form, and that a lamp for the production of these rays should, like the sun, show a continuous spectrum, and possess the greatest number of blue, violet, and ultra-violet and also luminous heat-rays. It is, he said, only the carbon arc lamp that gives a continuous spectrum, whereas all other lamps show a line spectrum —i.e., luminous lines broken by dark intervals. At the Finsen Institute two types of carbon lamp are used—one large, using 75 amps. at 55 volts, the other small, using 20 amps. at 55 volts. Seventy-five amps. is the highest practicable current that can be utilised to give with 55 volts a powerful, chemically active, and quietly burning light. The upper carbon of the 75 amp. lamp should be the larger and thicker (300 × 31 mm.) and attached to the positive pole. The lower carbon should measure 300 × 22 mm. and be attached to the negative pole. Corresponding measurements for the smaller lamp should be: upper carbon 300 × 12 mm., lower carbon 300 × 8 mm. The lecturer showed many of the various types of lamps on the screen, and detailed his objections to their use mainly on the grounds that their voltage was too high or their ampèrage too low, as well as on the ground that several of them give a broken spectrum. He then described how the apparatus should be installed and applied, with the necessary precautions to take. The lamps should not be allowed to swing, but slide up and down on their guide-rods; draughts should be minimised not only in the interest of the patient, but to keep the lamp as steady as possible; the walls should be distempered in a dark colour to avoid the discomfort of reflected heat-rays and the carbons should be so adjusted as to throw a cone of light upon the patient. Two large lamps will suffice for eight patients, sitting astride upon chairs, any unequal distribution of the total light being compensated by occasional exchange of position.

The duration of exposure will depend, said Dr. Strandberg, on the local reactions, blisters, erythema, &c., and the general condition of the patient. Thus, patients with lung disease should have 10 to 15 minutes' exposure to begin with, and those without lung complications may have 25 to 30 minutes' exposure from the first. Children, of course, should have shorter exposures; afterwards a tepid shower bath is useful. Severe heart disease, arterio-sclerosis, and nephritis of non-tuberculous origin are contra-indications to this form of treatment. Slight rises of temperature (100°–101°F. per rectum) are not a contra-indication, but where the temperature exceeds 102° the baths should be stopped for a day or two, and then, beginning with reduced exposures, gradually increased. Hæmoptysis, in Dr. Strandberg's opinion and experience, is not a contra-indication. Out of 147 patients treated, only 2 had hæmoptysis who never had it before. Light treatment of tuberculous laryngitis should be combined with local treatment, the galvano-cautery, excision, &c., and local treatment should begin when the patient's temperature has nearly fallen to normal and his general condition has improved, since the whole object of the light baths is to alter the biological immunity reaction. The treatment should be continued for four to six weeks after all signs have disappeared. Combined pulmonary and laryngeal cases should be treated with small doses. Deflected sunlight treatment of the larynx is useless because only a small amount of the light can be utilised; it is impossible or difficult to light up the affected spots, and the chemical components of the light are absorbed by the mirrors. Pictures of various methods of local application of light to the larynx were shown, amongst them, Cemach's with Kromayer mercury-vapour lamp, and Wessely's, which, after cocainisation, utilises Killian's suspension method or Seiffert's autoscope. However good the results of such treatment may be they cannot be due to local effects. Probably they are the result of a more or less total exposure assisted by the faucial illumination.

Turning to figures, Dr. Strandberg said that he has had 41 cases of *aural tuberculosis* treated by operation and by light. Of these, 9 are not yet completely dry, 1 died of phthisis, and in 23 cases a radical operation was rendered unnecessary. Sixty cases of *pulmonary tuberculosis* have been treated by Ostenfeldt at the Finsen Institute with the following results: Of 16 cases in Turban stage 1, 7 improved and 9 remained stationary. Of 17 in stage 2, 6 improved, 7 remained stationary, and 4 became worse. Of 25 in stage 3, 5 improved, 13 remained stationary, and 7 became worse. These figures seem to offer a strong argument in favour of light treatment in pulmonary tuberculosis, and still better results might be anticipated if it were to be carried out in a sanatorium. There were 203 cases of *tuberculosis of the larynx* submitted to light treatment. Of these, 11 still remain under treatment, 10 have improved, and 79, for one reason or another, have discontinued treatment. Of the 79, 45 improved, 13 remained unchanged, 9 became worse, and 12 died. Of the 113 cures, 77 were cases of purely intrinsic disease, 37 were both intrinsic and extrinsic, and 2 were extrinsic. These results confirm Sir StClair Thomson's dictum that the greater danger lies in cases of extrinsic tuberculosis.

The lecturer showed at the conclusion some coloured slides of laryngeal disease with the results of treatment.

Discussion.

Discussion was opened by Sir STCLAIR THOMSON, who paid a warm tribute to the work done by Dr. Strandberg at the Finsen Institute in Copenhagen. England, he said, was notoriously a slow starter, and after two years of agitation Midhurst had only now fitted a complete light installation. This method of treatment offered more chances of cure, but one should not forget that sanatorium treatment alone sometimes does a great deal of good, and at least as much as ever tuberculin did. Dr. Strandberg was to be congratulated on his results, and also on his frankness in publishing them. The Midhurst installation had been made in Copenhagen, and had been put in charge of a Danish nurse, so they had done everything to bring it up to date.

Mr. SOMERVILLE HASTINGS had visited Leysin and seen the sunlight treatment in operation there, and was convinced of its efficacy, since he was not struck by either their surgical or hygienic methods, and the good results must, therefore, have been due to the sun. As regards Wessely's treatment, which he had seen at Vienna, he said it had impressed him greatly because of the great relief it afforded to the pain on swallowing and other unpleasant complications of tuberculous laryngitis. His experience of light treatment in cases of lupus of the nasal passages, pharynx, and larynx was unfavourable, and the results were not so good as with the cautery.

Dr. A. EIDENOW gave the results of his researches, along with Dr. Leonard Hill, and others, into the employment of lamps of various types. He said that there is no arc which gives a continuous spectrum,

the spectrum of the carbon arc becoming interrupted in the lowest wave-lengths. Only the lower wave-lengths produce erythema and erythema is the important factor, since it can raise the hæmobactericidal power of the skin. Those who suffer from chronic tuberculosis have a very low blood resistance—i.e., a low hæmobactericidal power. Hence the necessity for very careful dosage. Excessive dosage, whether by arc or Hg vapour, lowers the bactericidal power of the blood, and makes the patient worse, and in animals will hasten death. There is, too, a definite optimum area of skin to be irradiated so as to have the most favourable influence on the bactericidal power of the blood—in the case of the rabbit, 20–24 sq. cm. In the matter of technique, then, a comparatively small area of the body (about one-fourth) should be irradiated with the production of a limited erythema, and the time to undertake local treatment is when the blood resistance is high. He congratulated Dr. Strandberg on his good results in a series of cases far more numerous than his own.

Sir JAMES DUNDAS-GRANT dealt with his experience of the Wessely treatment and the application of the so-called cosine law, that the intensity of light is proportional to the cosine of the angle of incidence.

Dr. STRANDBERG, in reply, reiterated his objections to Wessely's theory, that it is not really local treatment, and that quite as good results could be more easily obtained by placing the patient on a couch and giving him a total light bath.

Dr. WATT, in conveying the thanks of the meeting to Dr. Strandberg, paid tribute to his pioneer work in the treatment of tuberculosis by light.

On Saturday, Nov. 20th, there were excursions to various sanatoriums—Midhurst, Frimley, and King George V.—and the medical superintendents of these institutions acted as hosts.

On Monday, Nov. 22nd, a large number of visitors attended demonstrations at the Brompton Hospital by Dr. L. S. BURRELL, who exhibited amongst other objects of interest a compressed air chamber to hold five people, the value of which, according to Dr. Burrell, lies in the breathing of oxygen by patients in the chamber. He also showed a room in which several patients were seated round a steaming cauldron of creosote. The bronchi of a patient were then injected with a solution of lipiodol to discover a bronchiectatic cavity; the skin over the small space between the cricoid and thyroid cartilages was cocainised, and then an intratracheal injection of novocaine was given followed by a few c.cm. of lipiodol; very shortly afterwards the X ray of the lung was on view. Dr. Burrell also did a refill in a case of artificial pneumothorax and so concluded a demonstration of unusual interest and variety.

At 3 P.M., in the House of the Royal Society of Medicine, under the presidency of Dr. F. RUFENACHT WALTERS, Dr. P. F. ARMAND-DELILLE, of Paris, delivered an address on the

Diagnosis of Bronchiectasis and Lung Cavities by Intratracheal Injections of Lipiodol.

In cases, he said, where cavity was suspected but where tubercle bacilli were not present in the sputum and the X ray picture was not satisfactory, intratracheal injections of lipiodol made it possible to determine with absolute exactitude the topography of a cavity, and whether there was one or more. The procedure, due in the first instance to Sicard and Forestier, was, in his opinion, specially suitable for children. It could be adopted wherever the stethoscope gave evidence of a cavity without making it possible to say definitely that it was present. It was not a necessary procedure in cases of pulmonary tuberculosis when the sputum was found to contain tubercle bacilli, and at X ray examination the cavity was portrayed characteristically with a light centre and dark, defined circumference. Cavernous breath sounds and whispering pectoriloquy in the lower part of a lung might indicate either a cavity or a pleurisy, or a fibrosis (sclerosis) following a basal pneumonia with dilatation of the bronchi in some cases. Where there was partial pleurisy with a little pus it was important to know what connexion there might be between a basal cavity and other parts of the lung because of the possibility of operation. In such cases lipiodol was useful. Lipiodol was a strong solution of iodised oil warmed to blood heat (106° F.); 15–20 c.cm. were injected by means of a specially designed curved needle and trocar into the space between the cricoid and thyroid cartilages after cocainisation. By leaving the cannula in position a further 15–20 c.cm. could be injected if necessary.

In his own cases—60 in number, said Dr. Armand-Delille, only one, a girl of 15, had suffered from temporary dyspnœa; no other accident had followed, and there had never been any manifestation of iodism. The most useful application of the method was in cases of bronchiectasis. The disease showed very characteristic symptoms—long-continued cough, sputum, circulatory and trophic troubles, and physical signs in the middle and lower part of the lung. In such a case the X ray showed nothing but an irregular shadow, whereas with lipiodol dark spots, oval or round and of the size of a pea to a nut, were seen confluent with or adjacent to the bronchi. There were various types of dilatation: (1) Doigt de gant, or finger-glove; (2) cylindrical; (3) fusiform (common in children who had had whooping-cough or broncho-pneumonia); (4) ampullary; and (5) sclerosis with signs of irregular dilatation of the bronchi. The usefulness of the lipiodol method of diagnosis was not confined to such cases. It could also be used to show up cysts communicating with a bronchus, or an abscess which had penetrated upwards through the diaphragm. Finally, said Dr. Armand-Delille, the method had some therapeutic value, its repetition being sometimes followed by improvement in the patient's condition, such as lessening of cough and sputum.

Discussion.

Dr. F. G. CHANDLER considered the intratracheal injection of lipiodol a method of precision in the diagnosis of bronchiectasis, and stated that he had used it in 50 cases at Victoria Park Hospital. He gave details of some cases and showed numerous X ray pictures.

Dr. G. SCHRÖDER had used a 10–40 per cent. injection of iodipin, but had given it up in favour of bromipin as this was more fluid. He warned his hearers against its use in active tuberculosis of the lungs where it had produced severe focal and general reactions.

Dr. L. S. BURRELL showed X ray photographs of lipiodol in the normal lung and in a tuberculous cavity at the apex; he thought the method of value in some cases of neoplasm, the lipiodol stopping abruptly at the neoplasm and flowing into the normal lung on either side.

Dr. W. G. KINTON had found definite improvement in the condition of patients after two injections.

Dr. F. R. WALTERS conveyed the thanks of the Conference to Dr. Arnand-Delille, who replied briefly.

Resuming at 5 P.M.,

Dr. GEORG SCHRÖDER, of Schömberg, Würtemberg, read a paper on

Specific Stimulation Therapy and Protective Inoculation Measures in Tuberculosis.

As yet, he said, there were no specific remedies for tuberculosis in the human body that would either heal up the lesions or immunise the individual against infection; all remedies that might be regarded as specific had only a more or less specific stimulant action upon tuberculous tissue. The tuberculous patient was in a position of great delicacy as regards the so-called specifics, as these had the power of exciting the formation of tuberculous tissue. Both of these characters distinguished them from non-specific stimulant remedies (protein bodies, radiation, chemotherapeutic remedies). The specific stimulant remedies, continued Dr. Schröder, were not antigen. The antibody theory was not applicable here,

Nor were they immunising remedies. Sensitiveness to tuberculin—i.e., the increased tendency to inflammation of the tissues—so-called allergy—was a manifestation of immunity. In the tubercle-infected body every cell system was in a state of over-sensitiveness to the antigen and its products and also to all other stimuli. Only the living antigen gave rise to this allergy. Any artificial blunting of allergy, in the sense of Hayek, was to be avoided as of no value. In cases with so-called positive anergy, allergy rapidly returned; tuberculous metastases were seen more often in such cases, and visible tuberculous foci did not heal up, in spite of the so-called biological recovery. To maintain and increase allergy was the aim. For this purpose it was unnecessary to distinguish in practice between toxin sensitiveness and tubercle sensitiveness.

In choosing cases for specific stimulant therapy, said Dr. Schröder, the following points were helpful: (1) the clinical-anatomical nature; (2) the allergic behaviour; (3) the state of the blood. Contra-indications especially to be noted were high degrees of fever, tendency to metastasis in other organs, the more serious disturbances of the nervous system and of the organs of circulation, and the preponderantly exudative form of the tuberculosis. The employment of specific stimulant remedies in tuberculosis of children in the secondary stage was most questionable. The useful effect of specific remedies in patients was to be controlled: (1) by careful clinical observations; (2) by repeated testing of the allergic behaviour; (3) by regular blood- and serum-tests (blood count of Arneth, blood-sedimentation tests, lipase, and serum albumin values).

Vaccine Treatment with Living Virus and Protective Inoculations.

"We can only immunise against tubercle," said Dr. Schröder, "if we produce with a living virus a focus which is latent and does not spread." The best-known tuberculosis investigators were agreed on this fundamental point and protective inoculation against tubercle rested on this basis. Some had attempted immunisation with tubercle bacilli from cold-blooded animals (Möller, Friedmann). Selter employed vital tuberculin containing weak but still living tubercle bacilli. Recently Möller had recommended intracutaneous application of fully virulent virus; others, such as Calmette and Langer, employed for protective inoculation non-pathogenic strains of tubercle bacilli weakened in various ways. By personal investigation he was successful in making tubercle bacilli non-pathogenic by growing them in extracts of lymphocytic organs, and in obtaining some protection with his vaccine against bovine tubercle in rabbits, and increasing their resistance against subsequent virulent infection. Whether with any of these methods, which attempted an active immunisation, noteworthy cures of advancing tuberculosis in men were obtainable, was still in doubt. He was very sceptical about passive immunisation, and regarded serum treatment as nothing else than a non-specific stimulant therapy. Of non-specific remedies lipatren had given him the best results in this way. Specific therapy should always be carried out under the strictest clinical control, and usually in a hospital or sanatorium. In ambulant practice the control of patients necessary for these methods of treatment presented many difficulties. The general practitioner might perhaps be in a position to carry out the treatment. The results obtained by such methods could not be stated statistically. Separate cases alone decided the value of such remedies, and many patients profited by them in conjunction with other sanatorium methods.

Discussion.

Dr. HYSLOP THOMSON stated that in his opinion there was no specific therapeutic agent which healed or conferred immunity in tuberculosis; but specific therapy, together with sanatorium treatment, was useful in certain types of the disease. Tuberculin should always be given in minute and carefully gauged doses. Although tuberculin treatment had been largely discontinued in England, both in Germany and in France it was still employed. He believed in specific tuberculin therapy because post-mortem records showed that healing took place by a process of auto-inoculation, and resistance and disease were so evenly balanced that little was needed to turn the scale in the patient's favour with the production of sclerosis. He thought the reasons why tuberculin had gone out of use in England were: the number of tuberculins on the market, the absence of standardisation (he called attention in this respect to a League of Nations Committee on the standardisation of serums), and the variety of media employed for cultivation of the tubercle bacillus. He would like to know on what considerations cases for treatment should be selected, and what form of tuberculin should be administered. Personally he used the intradermal test in diagnosis.

Dr. G. MARSHALL advocated protective inoculation. Its value could be tested, for example, in the Zoological Gardens and in the case of human beings in religious and other communities where inmates are living under standardised conditions.

Dr. TRAILL had observed improvement with tuberculin in chronic cases of tuberculosis in which rest had not done any good. He called attention to the apparent variability of batches of serum from the same laboratories by reason of which similar results in similar cases could not be reproduced.

Dr. CAMPBELL THOMSON considered that tuberculin was useful in local disease, as well as in ocular troubles, but had not proved its value in pulmonary tuberculosis. Moreover, it was not always easy to dissociate the tuberculin treatment from sanatorium treatment.

Dr. T. R. ELLIOTT had used tuberculin for 14 years in pulmonary tuberculosis, but had given it up, using it now only in disease of eyes and lymph glands. Perhaps the cause of failure was that pulmonary tuberculosis was not usually a pure infection, but was complicated by secondary infections. He mentioned that he was experimenting at present with tuberculin administered to babies born of tuberculous mothers and removed at once to a special home for the purpose of protective inoculation.

Dr. ARMAND-DELILLE mentioned that he used *antigène méthylique* (Calmette), a preparation which acted exactly like tuberculin, giving good results without causing fever or undesirable reactions.

Dr. F. PARKES WEBER admired the manner in which Dr. Schröder had explained the modern attitude towards the theory of the action of tuberculin. Tuberculin was a toxin which the individual could accustom himself to some extent, as half the world did against tobacco and one-eighth of the world did against alcoholic drinks. This tolerance—mithridatism, as he called it—towards the toxin harmed the patient because it counteracted the particular effect on the reticulo-endothelial tissues which was one of the chief factors in the cure of tuberculosis.

Dr. WALTERS considered that a large number of individuals were not infected with tubercle until very late periods in life, and therefore it would be difficult to determine when to begin, and for how long to continue, protective inoculations of tuberculin. The selection of cases for injection was also difficult; it was the old problem of how to get hold of the early cases. Cumulative doses were very dangerous.

Dr. SCHRÖDER, in reply, extended a hearty invitation to his English hearers to attend the German congresses.

REBUILDING OF MIDDLESEX HOSPITAL.—Prince Arthur of Connaught last week explained the rebuilding plans to a meeting of subscribers. The new hospital will again take the "H" form, but the court-yard will be wider and all the general wards will be cross-ventilated. The west wing will be built first; it will afford accommodation for a gynæcological unit of 24 beds, the gift of an anonymous donor, and a children's unit of similar size. This portion of the hospital will be associated with the name of Mr. Bernhard Baron. The central cross-piece will be built next and the east wing along Cleveland-street last, the exterior will be of red brick and stone with classical details. His Royal Highness expressed the hope that in due course wards would be provided for paying patients, an object towards which the trustees of the second Lord Ludlow have given £10,000.

GENERAL MEDICAL COUNCIL.

PRESIDENT'S ADDRESS.

THE Winter Session of the General Medical Council was opened on Nov. 23rd, Sir DONALD MACALISTER presiding.

The PRESIDENT began by referring to the death since the last session of Sir Henry Morris, for ten years treasurer of the Council; Dr. J. C. McVail, for the same period Crown Member for Scotland; and Dr. D. N. Knox, who had represented for 12 years the Royal Faculty of Glasgow. Prof. L. P. Gamgee, he said, now took Sir Gilbert Barling's place as the representative of the University of Birmingham, while Sir Humphry Rolleston had resigned his place as representing the Royal College of Physicians of London but had returned as member for the University of Cambridge. He continued :—

Affairs in the Irish Free State.

"The Medical Act, 1926, of the Irish Free State has been continued from August 21st for successive periods of one month, and still by its operation maintains the previous arrangement by which the Medical Acts of this country are made applicable to Southern Ireland. I am informed that conferences have taken place between the Privy Council and other Government departments in this country, together with representatives of the Free State Government, on the question of our future medical relations. As a result proposals have been formulated for an amicable agreement between the Governments concerned. This agreement, if duly adopted and ratified, gives promise of a practicable *modus vivendi* which may be generally acceptable. Probably a further conference will be necessary for its final adjustment. But it must be ratified before the Free State Medical Act expires in February, or new legislation will be required.

New Brunswick.

"The Lord President was pleased to bring before His Majesty in Council the representations of the Executive Committee regarding a recent change of the law in New Brunswick, to which I made reference in June. These representations have been judged to be well-founded, and accordingly an Order in Council, dated Nov. 5th, 1926, has been issued, declaring that New Brunswick no longer affords to the registered medical practitioners of the United Kingdom such privileges of practising in the Province as to His Majesty seem just. The Order of Oct. 4th, 1913, by which reciprocity with New Brunswick was established, is therefore revoked, and medical diplomas and degrees hereafter granted in the Province will not be registrable in the Colonial List.

The British Pharmacopœia.

"The Lord President has further acceded to the request of the Council, formulated on June 4th, 1926, and has taken steps for the appointment of a small committee, on which the Council is represented, with power to make inquiries, to collect information, to receive evidence, and to make recommendations, on the question whether it is desirable to make any, and if so what, alterations in the existing law or practice relating to the preparation or publication of the British Pharmacopœia and to its adaptation to the requirements of the British Empire. I have grounds for stating that this committee is at present engaged in making inquiries and collecting information bearing on the subject of its reference.

The Poisons and Pharmacy and Dangerous Drugs Acts.

"Another committee, appointed by the Lord President, is sitting to consider the whole question of the scope and administration of the Poisons and Pharmacy Acts, and the regulations made thereunder, so far as poisons other than 'dangerous drugs' are concerned. On the nomination of the Executive Committee I have been appointed a member and have arranged to take part for the present in the Committee's inquiries and deliberations, which are now proceeding.

"The Secretary of State for the Home Department is authorised by the Dangerous Drugs Acts Regulations to refer the question whether a particular duly qualified medical practitioner is supplying, administering, or prescribing 'dangerous drugs,' for himself or others (otherwise than as required for medical treatment), to a tribunal of three practitioners in England and three in Scotland respectively, one of whom is to be nominated on behalf of this Council in each case. As speedy nominations were requested, the Executive Committee proposed Sir Humphry Rolleston for England and Dr. Ashley Mackintosh for Scotland, and by invitation sent up also the names of certain other members of the Council, empowered to act on the respective tribunals in the absence of those first named. The members proposed have agreed to act and have been duly approved by the Secretary of State."

Inspection of Indian Universities.

The President announced that Sir Norman Walker and Colonel Needham were revisiting India for a tour of visitation and inspection of the courses of study and examination required for university medical degrees in that country, and to make reports thereon to the Secretary of State for India and to the Council. The President indicated that the opportunities for observation, consultation, and conference offered by the University and other authorities of India would prove of essential service to the cause of medical education in India, while to the Council, as the body whose recognition of Indian medical diplomas for registration is by law equivalent to a guarantee of their sufficiency for efficient practice in medicine, surgery, and midwifery beyond the limits of India, the visitors' reports would be of primary importance and value. It is of interest, he said, to note that in other parts of the Empire a desire is manifested for similar visits by representatives of the Council. The Governments of the Straits Settlements and Federated Malay States have forwarded a cordial invitation to Sir Norman Walker and Colonel Needham to extend their tour to Singapore as official guests. The President had learned from the Deputy Governor that an inspection of the King Edward VII. College of Medicine, Singapore (whose diplomas are already "recognised") by the Council would be of much service, and the Executive Committee of the Council had recommended acceptance of the opportunity.

The President continued :—

Foreign Inspections.

"Sir Edward Coey Bigger has, during the autumn, been travelling in Canada, Australia, and New Zealand as a member of the Empire Parliamentary Delegation. He was provided with introductions, as a member of this Council, to a number of the medical authorities in these dominions. Though his stay at any one centre was perforce brief, I gather from his letters, and from those sent me by presidents, deans, and others, that his visits were everywhere welcomed, and that he was put in possession of information respecting curricula, examinations, &c., which cannot fail to be of interest and value to the Council. He was able also, while the guest of the Governor of Ceylon, to visit its medical college and to inform himself regarding its activities. These experiences suggest that as communications, aerial, marine and terrestrial, are gradually improved, the time may come when it will be feasible, as beyond question it would be mutually beneficial, to organise frequent and regular, rather than rare and occasional, visits to professional bodies overseas, who are occupied, like us, with problems of medical education and registration in distant parts of the Empire."

The New Medical Curriculum.

The President concluded by stating that the Examination Committee and the Education Committee had been actively engaged during the recess

in gathering information respecting the methods and standards of professional examination employed by the licensing bodies, and in ascertaining the extent to which the new medical curriculum is being brought into operation in the United Kingdom. "They may think it expedient," he said, "to present separate interim reports for the information of the Council on these subjects. The spheres of the two committees, however, include much common ground, and I understand that a joint conference may be proposed, for the coördination of their views and experience, before definite reports are submitted to you."

A vote of thanks to the President, proposed by Dr. W. Russell, seconded by Sir Norman Walker, was passed by the Council. The Registrar then read the official notification of the appointment to the Council of Dr. L. P. Gamgee, representing the University of Birmingham, and Sir Humphry Rolleston, Bt., representing the University of Cambridge; these members were introduced respectively by Sir Holburt Waring and Sir Robert Bolam. The Council proceeded to confirm disciplinary action taken by the Dental Board, and to receive reports from the Dental Education and Examination Committee. It then went on to consider a number of penal cases.

MEDICINE AND THE LAW.

Action for Negligence: Alleged Failure to Diagnose Fractured Collar-Bone.

THE action begun on Nov. 16th, in which Mr. E. H. Battershill claimed damages from Dr. A. C. Mann, of Lauderdale House, Gresham-road, Staines, for injuries alleged to be due to the latter's negligence and lack of skill, ended on the 22nd in the disagreement of the jury. Thus each side has to bear its own costs and the plaintiff is at liberty to begin a fresh action if he chooses. Mr. Justice Horridge made no novel pronouncement upon the responsibilities of medical practitioners, and the case depended, as usual, upon its own facts. The plaintiff's story was that he fell down last December and pitched upon his left shoulder. Dr. Mann was sent for, examined him, assured him nothing was broken, and advised putting the arm in a sling. Pain developed, and a fortnight after the accident the patient consulted another doctor, who diagnosed a severe fracture of the collar-bone. A radiograph then taken revealed a fracture and an overlapping of the broken parts to the extent of 1½ inches. The plaintiff's case was that an X ray photograph should have been taken in the first instance, and play was made with the following passage from the annual report of the Medical Defence Union: "In conclusion the president emphasises the urgent desirability of an X ray examination being made in every case of injury to a bone or joint." The main issues of fact appeared to be whether the fracture existed when Dr. Mann first made his examination and whether the displacement of the bone was then ascertainable. The scientific issues concerned the probability of the absence or presence of displacement and the correct treatment accordingly. Expert evidence was given by Sir George Cheatle for the plaintiff and by Sir Herbert Waterhouse, Sir Robert Jones, Sir Joseph Skevington, and Mr. Frank Romer for the defence. Mr. Romer described a case where a jockey (F. B. Rees) broke his collar-bone while racing, the fracture being in much the same spot as the plaintiff's; there had been no initial displacement, the periosteum keeping the bones in place until (during examination) the jockey lifted his arm, whereupon displacement occurred. Sir Joseph Skevington, during his cross-examination, stated that he thought the gap between Dr. Mann's visits on Dec. 9th and 13th was rather wide, and that the evidence of swelling and loss of use of the fingers on the 13th might have suggested a fresh diagnosis and recourse to radiography: but he added that he had known Dr. Mann for many years and had always found him careful and competent.

ROYAL SOCIETY OF TROPICAL MEDICINE AND HYGIENE:

ANNUAL DINNER.

AT the dinner of the Royal Society of Tropical Medicine and Hygiene, held on Monday last at the Hotel Victoria, London, Dr. Andrew Balfour, the President, in the chair, Lord Balfour was the principal guest. Mr. W. Ormsby-Gore, Under Secretary of State for the Colonies, and Sir Samuel Wilson, the Permanent Secretary, were also present.

Dr. ANDREW BALFOUR introduced Lord Balfour happily, saying that while he could not claim to be a relative of the distinguished statesman, he was of the same clan, and the identity of names in a recent visit to America had been valuable to him, while all the United States recognised Lord Balfour's pre-eminent position.

Lord BALFOUR proposed the toast of the Society, and recalled to his hearers the remarkable growth of inter-communication which had taken place in the past few years between the various divisions of scientific study. Until quite recent days, he said, men of science had remained absorbed in their particular specialties, doing splendid work, but regarding their separate problems from separate standpoints. This was changing, and he pointed to the proceedings which had just taken place at the Inter-Imperial Conference, where the section which had under its attention the various problems of research had recognised the extreme importance of inter-communication, as only by fusion of results could the needs of the world be met. Speaking of the Committee of Civil Research, he claimed for this body that, although it was young, it had already displayed energies which should make it a valuable instrument in the coördination of knowledge, and—as particularly bearing on the interests of those present—he alluded to the work done by the Committee in regard to the problem of the tsetse-fly in Africa. Lord Balfour found it appalling to reflect that, while the creation of the domestic animal was one of the greatest of prehistoric achievements, over a vast area in Africa the use of the domestic animal was prohibited by the ravages of flies. *Homo sapiens*, he said, might be the crown of creation, but the fact remained that he was having a very hard struggle in many places to retain his pre-eminence over organisms which certainly were not the crown of creation. Much investigation was called for by students of tropical medicine if only in this one direction; and in wishing prosperity to the Society he said he could not conceive a greater benefit to the work of the investigators than to have a home in London which, on their return, they could treat as a centre for the record and exchange of experiences. He knew that he had the endorsement of his audience in wishing long life to the Society.

Major E. E. AUSTIN, in reply, said that the particular things which he had been asked to bring out, in narrating the history, objects, and recent activities of the Society, were circulated in printed form among the guests who, he hoped, had read them. He alluded to James Cantlie as the original parent of the Society, in association with Patrick Manson, and pointing out how fortunate the Society had been in its various presidents, deplored the untimely death of Sir William Leishman. He concluded by urging the need of the Society for a house of its own, successful though it had been as a guest in the house of the Medical Society of London.

Mr. ORMSBY-GORE proposed the toast of "Britain in the Tropics and Its Defenders" in eloquent terms. He claimed that for a long period all our colonial possessions had been administered with a view of advancing the welfare of the native peoples, and above all things, he said, the benefit which was most required to turn perilous localities into veritable health resorts was organised medical science. On the many journeys he had taken he had found every-

where evidence that the application of scientific knowledge was necessary for any real advances, and in the struggle of men against the attacks of insects nothing would prevail except that speed and mobility which could only be the outcome of applied science.

Sir JOSEPH COOK, High Commissioner for Australia, in the course of his reply to the toast, begged more of his audience to come to Australia and learn at first hand how fair the prospect was in that country and the territories under its administration. The toast was also replied to by Vice-Admiral Sir J. CHAMBERS, Director-General of the Royal Naval Medical Service.

Colonel W. P. MACARTHUR, Professor of Tropical Medicine in the Royal Army Medical College, proposed the health of the guests, which was replied to by Sir JOHN BLAND-SUTTON, who caused merriment among the guests by describing in strictly heraldic terms the coat-of-arms with its quarterings and crest which he would have suggested if he had been invited to design the armorial bearings of the Society.

The health of the Chairman was then proposed by Sir MATTHEW FELL, Director-General of the Army Medical Service, when Dr. BALFOUR, in reply, thanked Dr. C. M. Wenyon, the Secretary of the Society, and his collaborators for the pains which they had taken in regard to the function.

IMPERIAL CANCER RESEARCH FUND.

ANNUAL REPORT.

A MEETING of the General Committee of the Imperial Cancer Research Fund was held on Nov. 23rd, the Duke of Bedford presiding.

Sir HUMPHRY ROLLESTON, Chairman of the Executive Committee, moved the adoption of the annual report. He pointed out that scientific progress is characterised by successive periods of great activity, with periods of relative quiescence between. Each period of activity is started by some salient discovery or fruitful conception, the working out of which engages for a longer or shorter time the energies of those employed in that field. Cancer research exhibits this phenomenon in a very striking manner. The first period is that following the discovery by Jensen and Borrel of the transplantability of the malignant growths of the mouse. The second period followed the work of Fibiger, Yamagiwa and Ichikawa, and Tsutsui on the actual production of cancer anew, starting with normal animals. If the interest and activity aroused be taken as an indication, the work of Gye and Barnard on cancer causation by ultra-microscopic microbes published 18 months ago can be regarded as starting still a third period in cancer research. A number of papers have appeared in Europe and America, and, as was to be expected, agreement has not yet been reached. Both the facts and their interpretation are in dispute, and in these circumstances it is necessary to exercise patience and continue the investigations. Of the various lines of work bearing on the validity of the conception of Gye, at present in progress in the laboratories of the Imperial Cancer Research Fund, that of Dr. A. H. Begg is farthest advanced. Dr. Begg, whose researches are provided for by the generous donation of Lord Athelstan, has worked with the Rous fowl sarcoma and with another new growth of the domestic fowl which, although differing in structure, behaves in the same way. His results confirm the existence of two factors, as advanced by Gye, in the successful transmission of these tumours, and will shortly be published. The laborious, time-consuming character of these researches cannot be too strongly emphasised, and the public should realise the impossibility of a quick decision on the important problems involved.

Sir ANTHONY BOWLBY seconded the motion, which was unanimously carried.

The PRESIDENT referred to the part played by the late Sir Henry Morris in the initiation of the Imperial Cancer Research Fund and to the fact that the Fund must always depend on donations and legacies if activities were to be prosecuted on a useful scale. It was satisfactory to note that the office expenses, including salaries, printing, stationery and advertisements, worked out at less than 7 per cent. of the total expenditure.

Director's Report.

The report of Dr. J. A. MURRAY, F.R.S., the Director, states that the work of the laboratory during the past year has included studies arising out of the problems presented by the development of tar cancer in animals, in continuation of the earlier work, and the investigations undertaken to test the validity of the conclusions of Gye and Barnard on the ætiology of malignant new growths. A paper by Dr. W. Cramer has been published in the *British Journal of Experimental Pathology* (1926, vii., 1) dealing with the production of tar cancer, in which he has shown that the inception of new growths can be accelerated by an intervention at a site remote from that to which the tar is applied. The other investigations concerned with tar carcinogenesis at present in progress are not yet sufficiently far advanced for report. The Director continues :—

"The work of Dr. Gye, as was to be expected, has aroused the liveliest interest, and has led to a renewed world-wide study of the tumours of the domestic fowl of the Rous type. Several contributions to the discussion have already been published in Europe and in America. The work of Dr. Begg on the Rous tumour and another tumour of the fowl of different structure which behaves in the same way will shortly be published. In our opinion the results obtained can be harmonised with Gye's conceptions with less subsidiary assumption than on any other hypothesis, but some workers in other countries have recorded discordant results and have therefore drawn adverse conclusions. The divergence of opinion is eloquent of the technical difficulties of all investigations on the ultra-microscopic viruses in which a reliable visual control for their presence and identification is absent. In addition, the unfamiliarity of the idea of two distinct factors (each of which is inert by itself) as necessary for the induction of disease, has been a stumbling-block for many who are not familiar with the features of cancer which distinguish it from the recognised infections. It is, however, idle to enter on a speculative discussion of our results and those of other workers at the present time. The subject is essentially one for experimental treatment, and the discrepancies and differences of opinion can be resolved in no other way."

In order to gain an insight into the mechanism underlying the strict specificities of transmission in virus diseases, Dr. G. M. Findlay has undertaken an investigation of inoculable warts in man and in the dog, and of the remarkable epithelial proliferations known as fowl-pox and pigeon-pox. An account has been published, in collaboration with Dr. R. J. Ludford. of the cell-changes in the latter conditions.

The Director described other work in progress at the laboratories of the Fund, and referred to the visit paid by him to America in September, at the invitation of the American Society for the Control of Cancer, to attend the International Conference held at Mohonk, New York State. The conclusions[1] drawn up by the Committee of the Conference, while bringing nothing very new, embodied a sane and practical statement of the approved practice at the present time.

[1] THE LANCET, Oct. 16th, p. 825.

COLLEGE OF PHYSICIANS OF PHILADELPHIA.—The Alvarenga Prize for 1926 has been awarded to Dr. P. S. Pelouze and Dr. F. S. Schofield, of Philadelphia, for an essay entitled The Gamophage. Competitors for next year's prize must send in their essays before May 1st, 1927 ; further details can be got from the Secretary of the College.

QUEEN ALEXANDRA MEMORIAL.—The contributions to this object now amount to £154,000, of which £74,000 has been raised in Scotland, £71,000 in England and Wales, and £9000 in Ireland. The money is to be used to widen the work of Queen Victoria's Jubilee Institute for Nurses. It is estimated that 3000 more nurses are needed to provide an adequate nursing service.

The Services.

R.A.M.C. COMMISSIONS.

A LIMITED number of commissions in the Royal Army Medical Corps, not exceeding 25, will be offered by nomination in January, 1927. Nominations have been allotted to London and Provincial Medical Schools, and intending candidates should apply to the various Deans. In addition, a certain number of nominations will remain at the disposal of the War Office. Candidates must be under 28 years of age on Jan. 31st, 1927, and will be required to present themselves in London for interview and medical examination towards the end of January. Full particulars may be obtained on application to the Under-Secretary of State, War Office, Whitehall, London, S.W. 1, and applications for consideration should reach the War Office not later than Jan. 10th next.

ROYAL ARMY MEDICAL CORPS.

Capt. H. Alcock to be Maj. (Prov.).

Capts. to be Majs.: K. A. M. Tomory, R. I. Sullivan (and remains secd.), A. R. Ross (Prov.), R. A. Anderson, and B. C. O. Sheridan.

Temp. Capt. R. W. D. Hewson relinquishes his commn. and is granted the rank of Capt.

W. H. D. Priest to be temp. Lt.

ARMY DENTAL CORPS.

Temp. Lt. R. G. Law, Dental Surg., Gen. List., to be Lt.

ARMY RESERVE OF OFFICERS.

G. R. Anderson de Montjoie Rudolf to be Lt.

TERRITORIAL ARMY.

Maj. R. Henry, having attained the age limit, is ret. and retains his rank with permission to wear the prescribed uniform.

Capt. W. Ainslie, having attained the age limit, relinquishes his commn. and retains his rank.

Capt. J. K. Holland, R.A.M.C., to be Div. Adjt., 53rd (Welsh) Div., vice Capt. J. D'A. Champney, vacated.

Lts. J. D. M. Cardell and A. F. G. Guinness to be Capts.

D. N. Buchanan, late Lt., 6th Bn. H.L.I., to be Lt.

General Hospitals.—Lt. K. V. Bailey, from the Gen. List, to be Lt.

ROYAL AIR FORCE.

Flying Officer W. A. Beck is transferred to the Reserve, Class D.2.

INDIAN MEDICAL SERVICE.

Temp. Lts. to be Temp. Capts.: Mohan Singh Segat, Chandu Lal Malhotra, Rajindar Singh Sandhu, Rama Shankar Varma, Shiv Das Suri, Kashi Ram Sahgal, Chandriam Ghurbamal Malkani.

To be Temp. Lts.: Patit Paban Chowdry, Abdul Majid Khan, Hari Krishna Handoo, Prabhakar Narayan Sathe, Balwant Rai Bhaskar, Sangham Lal, Shamsul Haque Wali Mohomed Siddiqui.

INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED NOV. 13TH, 1926.

Notifications.—The following cases of infectious disease were notified during the week: Small-pox 218 (last week 302), scarlet fever 1905, diphtheria 1124, enteric fever 49, pneumonia 1155, puerperal fever 44, puerperal pyrexia 170, cerebro-spinal fever 8, acute poliomyelitis 29, acute polio-encephalitis 3, encephalitis lethargica 35, continued fever 1, dysentery 21, ophthalmia neonatorum 127. There were no cases of cholera, plague, or typhus fever notified during the week. The total of cases of acute poliomyelitis and polio-encephalitis taken together is substantially less than that of previous weeks, the only county notifying more than 3 cases being Middlesex (Enfield 2, Hendon 1, Southgate 1), with isolated cases from the counties of London, Cambridge, Chester, Dorset, Essex, Kent (Broadstairs 1), Lancaster, Lincoln, Nottingham, Rutland (Uppingham 2), Stafford, Surrey, Sussex East, Sussex West, Warwick, Wilts, Worcester, and Yorks West Riding. Of the 218 cases of small-pox 164 were notified from the county of Durham, 6 from Northumberland, 22 from Yorks West Riding, 6 from Lancaster (Ashton-in-Makerfield), and 17 from Derby.

Deaths.—In the aggregate of great towns, including London, there was no death from small-pox, 3 (0) from enteric fever, 17 (0) from measles, 5 (1) from scarlet fever, 16 (3) from whooping-cough, 33 (6) from diphtheria, 91 (20) from diarrhœa and enteritis under two years, and 100 (26) from influenza. The figures in parentheses are those for London itself.

THE DISSOLUTION OF INSULIN.

To the Editor of THE LANCET.

SIR,—At the scientific meeting of the State Institute of Hygiene in Warsaw on Nov. 4th of this year, I read a paper on the separation from insulin of two extremely interesting new substances. This preliminary report can be amplified as follows.

From the insulin produced in our Institute (the clinical unit being 0·07 mg.) by an extremely mild fractionation procedure it was found that two substances could be obtained in a crystalline state, which are being designated as A and B.

The substance A is contained in the insulin in a large proportion, the yield corresponding to over half of the weight of insulin taken. Unlike insulin, it decreases the blood-sugar in 70–80 per cent. of normal rabbits, but in those with a high initial blood sugar it decreases the blood-sugar by 10–44 per cent. In rabbits with low initial blood-sugar it produces either no effect or causes increases from 5–20 per cent. This observation has led me to apply the substance clinically on diabetics and non-diabetics in conjunction with Dr. Marceli Landsberg, of Warsaw. From the small amount of cases investigated it would be premature as yet to reach a definite conclusion, but so far we had increases of blood-sugar or no effect in non-diabetics and marked decreases in diabetics.

As to the substance B, it represents a new hormone of complicated and not yet easily understood action. Substance B when injected or given per os causes marked and lasting increases in blood-sugar, so that we have produced hyperglycæmia and glycosuria in normal rabbits with six doses of 0·2 mg. of the substance per day. The substance B causes a high grade dilution of the blood with enormous retention of water, and if one takes that dilution into account blood-sugar increases amounted to over 800 per cent. The rabbits eventually died, and we are investigating the pathological changes, especially in the pancreas, on which a report will follow later.

As the substance B was found in insulin and the latter hormone in a number of organs, and, therefore, probably in food, and as it acts per os, one naturally suspects that this substance may have something to do with the causation of at least certain forms of diabetes.—I am, Sir, yours faithfully,

CASIMIR FUNK.

The Biochemical Department, State School of Hygiene, Warsaw, Poland, Nov. 20th, 1926.

THE MANAGEMENT OF INFECTIOUS DISEASE IN BOARDING-SCHOOLS.

To the Editor of THE LANCET.

SIR,—The address by Dr. A. I. Simey, printed in your last issue, is so carefully thought out and so illuminating that I hope he will pardon me if I make two comments from the point of view of one who was formerly in charge of the city fever hospital of one of our largest towns and who has since devoted himself to the pathology of infectious disease. Briefly stated these are as follows:—

(*a*) Dr. Simey mentions the structural difficulty in providing sufficient isolation accomodation form infectious cases. Has he tried bed, as distinct from ward, isolation? I found that, given marking and disinfection of the utensils of the patient and the wearing of rubber gloves and gown by the nurse when attending to him, it was safe to admit cases of almost any infection, except measles and chicken-pox, to a large ward occupied by patients suffering from a different disease without risk of cross-infection between the patient and the other occupants of the wards

In a school where sanatorium accommodation is necessarily limited, this would seem to be the method of choice.

(*b*) As regards the discharge of patients suffering from scarlet fever, it is, I think, nowadays generally agreed that the nasopharynx is the source of infection. I found that one could with safety discharge scarlatinal patients after four weeks, without regard to desquamation, provided that for a week at least they had been separated from contact with acute cases and had been treated by daily irrigation of the nose. After much experiment, I found that normal saline solution and weak (0·5 per cent.) permanganate of potash were the best, and did not defeat their purpose by setting up irritating catarrh. I found, however, that no amount of previous irrigation was efficacious if the patient was discharged from an acute ward.

The more I see of infectious disease, the less I believe in brick walls and disinfection. Everything seems to point to measures directed to the treatment of the patient himself and to aseptic nursing technique, and that is why Dr. Simey's address is, in my view, so excellent. Old shibboleths, however, die hard.

I am, Sir, yours faithfully,

A. KNYVETT GORDON, M.B. Camb.

Bedford-square, W.C., Nov. 21st, 1926.

PERFORATION OF GASTRIC ULCER DURING X RAY EXAMINATION.

To the Editor of THE LANCET.

SIR,—The case reported by Dr. F. W. Lang in your issue of Nov. 20th is probably an example of an occurrence which is less rare than is supposed. During the past three years I have seen two patients in whom it had happened during X ray examination, in each case at an overseas hospital. I also know of a case where an injudiciously conducted gastric analysis three days after a hæmatemesis was apparently the cause of recurrent hæmorrhage and death.

It is, I think, important to remember that severe pain or hæmorrhage is evidence of an active ulcerative process the extent of which is a matter of conjecture, and with this in mind it is well to postpone all strenuous forms of examination until the alleviation of symptoms gives reason for supposing that the penetration of the ulcer has been arrested. The rapid ingestion of a large mass of heavy material is the very antithesis of the dietetic treatment of gastric ulcer, and the recorded accidents are evidence of the soundness of the principles underlying this treatment.

I am, Sir, yours faithfully,

London, W., Nov. 19th, 1926. T. IZOD BENNETT.

RADICAL OPERATION FOR CARCINOMA OF THE ŒSOPHAGUS.

To the Editor of THE LANCET.

SIR,—I wish to make clear a statement in your report of my remarks at a meeting of the Section of Surgery of the Royal Society of Medicine on Nov. 3rd (THE LANCET, Nov. 13th, p. 1007). The case which I described was one in which an exploratory posterior mediastinotomy had been performed for carcinoma of the œsophagus, but in which the growth, situated just below the arch of the aorta, was too adherent to allow of its being separated from adjacent structures. I mentioned this case in order to illustrate that a mere exploratory mediastinotomy is not, per se, an extremely serious undertaking, as this patient lived for 11 months afterwards. I do not wish to give the impression that the patient lived 11 months after a partial œsophagectomy in the thoracic region, a feat which, as far as I know, has not yet been accomplished in this country.

I am, Sir, yours faithfully,

A. LAWRENCE ABEL.

Harley-street, W., Nov. 17th, 1926.

MEDICAL SCHOOLS AND THE LONDON UNIVERSITY BILL.

To the Editor of THE LANCET.

SIR,—The second reading of the University of London Bill brings to an issue certain considerations which I feel it my duty to lay by your favour before medical graduates of the University of London. I feel deeply responsible towards these graduates, whom I represent both upon the Senate and in Parliament. The large measure of support which was given to me at the Senate election last year, when my poll in the contested election was the largest ever recorded in any faculty—827, as against 281 cast for my opponent—makes me hope that I have interpreted the wishes of my constituents in the action I have taken in opposing the reconstitution suggested by the Departmental Committee. That reconstitution, it seems to me, has not been entirely realised by the medical schools. An admirable analysis of the effect upon the schools of the University of the regulations proposed has been contributed by Dr. Headlam, Bishop of Gloucester, in a letter to the *Times* :

"The control of the University is largely to be in the hands of outside members, and to be taken away from the representative body. Those who desire the independence and self-government of the Universities must feel that this is a most retrograde step. . . . Regulations are to be introduced by which the Senate may require the revision of the constitution, governing body, and statutes of a school of the University, and may interfere with the appeals issued by them, so that no . . . school will be able to appeal for money without the consent of the Council of the University, and will be obliged to consult the University before accepting benefactions. The University also may claim to appoint principal teachers in the schools. . . . The object of the Report and Bill is to give the Senate control over existing schools. If these regulations are given statutory authority the theological colleges will probably cease to exist as schools of the University."

Are the medical schools any more willing to accept these regulations than are, according to Dr. Headlam, the theological colleges? Is it acceptable to the medical schools that their principal teachers—a phrase which must include members of the medical staff—should in the ultimate issue be elected by a Finance Council, nearly half of whom will be Crown and municipal representatives, with no first-hand knowledge of the University and with political rather than educational qualifications for that post?

I happened to be in Chicago seven years ago at the moment when a member of the staff of a certain hospital school had been forced upon the staff by the direct personal influence of the mayor, exercised through municipal representatives upon the governing body of the school. The appointment was so unacceptable to the other members of the staff that they resigned *en bloc*. This action roused the public spirit of the citizens of Chicago, who, at a mass meeting, intimidated the mayor sufficiently to make him cancel the objectionable selection, whereupon the staff resumed their duties.

That seems to me an object lesson of what might happen if hospital appointments are to be influenced by political parties, municipal or governmental. The President, in the course of the debate on Friday, intimated that owing to representations from the theological colleges, he was prepared to insert amendments which should protect their position. I suggest that the medical schools might consider the advisability of following this example, by representations in the same quarter.

I am, Sir, yours faithfully,

E. GRAHAM LITTLE.

Wimpole-street, W., Nov. 22nd, 1926.

A HOSPITAL FILM.—The Prince of Wales last week visited the New Gallery for a private view of a Gaumont film depicting the work of King Edward's Fund. It is entitled "A Hundred Years of Progress," and illustrates a century's advance in the treatment of sickness and accidents.

Medical News.

SOCIETY OF APOTHECARIES OF LONDON.—At recent examinations the following candidates were successful in the undermentioned subjects :—

Surgery.—R. Bobo, Paris ; J. M. Moran, Manchester ; D. D. Stidston, St. Mary's Hosp. ; and L. D. Williams, Cardiff.
Medicine.—P. V. Bamford, London Hosp. ; R. Bobo, Paris ; S. B. Browning, Guy's Hosp. ; K. Roberts, Liverpool ; D. Jacobson, St. Bart.'s Hosp. ; and E. H. Waller, Charing Cross Hosp.
Forensic Medicine.—B. Best, Liverpool ; L. O. Jaggassar, St. Mary's Hosp. ; and H. Bundstrom, St. George's Hosp.
Midwifery.—B. Best, Liverpool ; J. De Rosa, Albany and London Hosp. ; B. Elliott, Durham ; L. J. Lawrie, London Hosp. ; L. W. Rose, Guy's Hosp. ; D. D. Stidston, St. Mary's Hosp. ; and N. W. Wood, Middlesex Hosp.

The Diploma of the Society, entitling them to practise medicine, surgery, and midwifery, was granted to S. B. Browning and J. M. Moran.

UNIVERSITY OF LONDON.—A meeting of the Senate was held on Nov. 17th, Sir William Beveridge, the Vice-Chancellor, being in the chair. Regulations were adopted for the recently established Academic Diploma in Anthropology. Mr. D. T. Harris, an internal student, of University College, was awarded the D.Sc. in Physiology for a thesis entitled Biological Action of Light. Sir Holburt Waring has been elected chairman of the Brown Animal Sanatory Institution Committee. The Semon Lecture (1926) will be given by Dr. A. Brown Kelly in the Lecture Hall of the Royal Society of Medicine, 1, Wimpole-street, London, W., on Thursday, Dec. 2nd, at 5 P.M. The subject will be Nervous Affections of the Œsophagus. Dr. Andrew Wylie, President of the Laryngological Section of the Royal Society of Medicine, will take the chair.

UNIVERSITY OF LEEDS.—The Council of the University has made the following additional appointments to the staff of the Cancer Laboratories, which are to be the main centre for cancer research in Yorkshire : Dr. J. S. Young, Lecturer in Experimental Pathology and Assistant Director of Cancer Research, and Mr. J. H. Channon, M.Sc., Biochemist in the Department of Experimental Pathology. Dr. Georgiana M. Duthie and Mr. G. A. Collinson, M.Sc., have been elected to research fellowships.

ROYAL DENTAL HOSPITAL : ANNUAL DINNER.—The annual dinner of the staff and past and present students of the Royal Dental Hospital of London was held on Nov. 20th at the Trocadero (Empire Rooms), at 7 P.M. Mr. W. H. Dolamore occupied the chair and presided over a large gathering, including representative guests. The Chairman, in proposing the toast of "Past and Present Students of the Royal Dental Hospital and Dental School," said with regard to the "Past Students" he would say, expressing his personal sentiments, that, first, they were professional men ; secondly, they were generous professional men ; and thirdly, they were generous professional men who carried out their work in a skilful manner, promoting the advancement of their profession. Three past students were associated with the three stages of metamorphosis through which the Royal Dental Hospital had passed. There was John Tomes, whose name was always selected as that of the representative of English dentistry. He was the moving spirit in the foundation of the hospital and in its early days spent much time searching in second-hand shops for fitments, so that old records would leave the impression that he was rather an antiquary than a scientist. John Tomes was also one of the few men in connexion with dentistry who had given his name to a part of the human body. The dental fibril is not spoken of as the dental fibril but is known as the Tomes fibril. Edwin Saunders was the man to whose generosity the hospital was indebted when it was moved from Soho-square to Leicester-square, and to him they were indebted for the establishment of the Saunders Prize. The man most associated with the next step was Morton Smale, with whose assistance the hospital moved from one side of St. Martin's-street to the other. Without his energy the authorities could never have ventured upon the expenditure of the large sum of money which the present building represents. Mr. Dolamore associated with the historical portion of the toast the name of Mr. J. H. Badcock, an old fellow student of his own who had wandered to Guy's, a school with which they had always had close association.

With regard to the present students he felt diffidence in speaking about them, because of the possible reply, wh ch was entrusted to the last winner of the Saunders scholarship. The present position of the hospital, which was the third subject of his remarks, he found a difficult thing to speak about. He had in the last few years occupied the post of treasurer to the Dental Board, and it had been his duty to be associated with the educational projects of that board, which fortunately was endowed with financial powers. Thus it devoted a considerable sum of money to dental schools, to the giving of bursaries to dental students, and to the promotion of research. But the board insisted that arrangements for the teaching should be adequate when making grants to carry out improvements which were necessary. As a result of such assistance it was certain that sooner or later new schools would also arise, and every school which had not met the situation would find competition up and down the country, probably in schools which were part and parcel of provincial universities.

The President concluded the address by welcoming cordially the support received from the Ministry of Health and the Dental Board.

Mr. Badcock, in reply, dealt with the changes which the school had undergone. To present students he urged the necessity of joining a defence union in order to protect themselves, so far as insurance was concerned, against accidents and illness ; and to join the British Dental Association "in that every man was a debtor to his profession." Mr. M. Lewis replied on behalf of the present students ; and the Dean, Mr. H. Stobie, on behalf of the school. After touching upon the changes in the staff, their loss by the deaths of Mr. J. Howard Mummery and Mr. Douglas Gabell, he recorded recent valuable gifts to the hospital. They were indebted to Mr. E. F. Ackery for the success of the "at home" that afternoon.

The toast of "The Visitors," proposed by Mr. A. L. Packham, was responded to by Prof. T. B. Johnston, Dean of Guy's Hospital Medical School. That of "The Chairman" was proposed by Mr. Norman G. Bennett.

SOCIETY OF M.O.H.'S ANNUAL DINNER.—The annual dinner of the Society of Medical Officers of Health was held in the Georgian Room at the Piccadilly Hotel on Nov. 18th, when the chair was taken by Dr. Robert Snell, M.O.H. for Coventry, and there was a large attendance of administrative and clinical health officers, largely of the younger generation. Sir Robert Bolam, in proposing "The Society," spoke feelingly of the difficulties of the preventive health service, crushed, as it was, between the upper millstone of its secular masters and the nether millstone of a public with a gift for passive resistance. For the solution of these difficulties he offered the cordial coöperation of their colleagues engaged in clinical and consulting practice. Dr. Snell, in reply, spoke of the present modest membership of his Society, numbering 2000 or so, in comparison with the 32,000 members of the British Medical Association, but foresaw the possibility of a time when these numbers might be reversed. He recounted the circumstances of the Society's birth in 1856, when 47 medical officers of health, none of whom had had any experience, were suddenly flooded on to the metropolitan area, so that they were obliged to meet and talk over how they should spend their time. Even now he doubted whether the country availed itself fully of their help, for the military authorities, who early in the present century had organised an *à la suite* sanitary service, had not yet found an emergency serious enough to call it up. "The Guests" were proposed by Dr. Charles Sanders, who remarked that a society might fairly be judged by the guests who assembled at its annual dinner, and spoke of the notable services to the public health rendered by those who were present. The Duchess of Atholl, in reply, said she regarded the school medical service as the most striking advance in public welfare made since 1902, including, as it did, the inspection and treatment of all the school children of the nation and the setting-up of open air, special and nursery schools. She felt that this work had gained much from the presence of women coöpted on education committees. Mr. Philip Snowden admitted that it was the first occasion on which he had met the public health service on a social occasion. For himself, he regretted he was no longer a local administrator, for, he said, "you see things being done." He paid a high tribute to the *esprit de corps*, the technical knowledge, and the enthusiasm of permanent officials. There was, he said, nothing in the world like our civil service, and the great problem "What to do with our educated boys ?" would find its solution in their absorption into public services which would brighten the lives and increase the health of the population at large. Mr. Snowden disclaimed personal familiarity with vital statistics, illustrating his disclaimer with a story of the newly-elected councillor who asked a more experienced colleague the meaning of a death-rate of 9·5. Nine dead, was the reply, and five on the point of death. But, Mr. Snowden went on, loss of working days from sickness was still six times larger than loss from industrial disputes ; financial economy in public health was met by the Proverb of Solomon : "There is that withholdeth more than is meet, but it tendeth only to want." Sir John Rose Bradford also replied in a few well-chosen phrases, in which he characterised the first duty of a physician as the prevention of disease. During the evening Mr.

Norman Williams delighted the company with some familiar songs and ballads. Besides the guests already mentioned there were present at the dinner Alderman Fred. Lee, Mayor of Coventry, Mr. G. A. Powell, Clerk of the Metropolitan Asylums Board, Sir Arthur Robinson, Lieut.-General Sir Michael Fell, Sir A. Boyd-Carpenter, M.P. for Coventry, and Dr. H. B. Brackenbury.

THE LATE DR. J. D. MCCRINDLE.—The death is announced, on Nov. 19th, of Dr. James Doig McCrindle, for many years medical officer of health for the borough of Northampton.

NEW SUNLIGHT CLINICS.—Princess Marie Louise has opened an artificial sunlight clinic at the Mildmay Memorial Hospital, Islington.—Sunlight and X ray departments were opened at Wigan Infirmary last week by Dr. Robert Knox.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION.—On Thursday, Dec. 2nd, at 5 P.M., at the house of the Medical Society of London, 11, Chandos-street, Cavendish-square, W., Dr. John Parkinson will lecture for the Fellowship on Cardiac Emergencies. The lecture will be free to members of the medical profession. There will be a two weeks' course from Dec. 6th at the Infants Hospital, under the direction of Dr. Eric Pritchard. It will include demonstrations and lectures, and visits to the Model Pasteurising Plant at Willesden, to Thavies' Inn, and to the Nursery Training School. Courses in obstetrics can be arranged at the Queen Charlotte's Hospital and the City of London Maternity Hospital, and the Fellowship can accommodate graduates with posts as clinical assistants at the Samaritan Hospital. In January there will be the following special courses: In medicine and surgery and the specialties at the Prince of Wales's General Hospital; in cardiology at the National Hospital for Diseases of the Heart (early application is desirable), in diseases of children at the Children's Clinic and the Royal Free Hospital, and in psychological medicine at the Bethlem Royal Hospital. A complete list of the special courses for 1927 may be had from the Secretary of the Fellowship at 1, Wimpole-street, London, W., who will also supply copies of other syllabuses, of the General Course Programme, and the *Post-Graduate Medical Journal*.

MEDICAL WOMEN'S FEDERATION.—A half-yearly meeting was held at Leeds on Oct. 22nd, with Dr. Christine Murrell, President of the Federation, in the chair. The national corresponding secretary of the Medical Women's International Association presented a report on the successful meeting of the council of the Association held on August 25th to 28th in Prague. The usual report was made on underpaid posts advertised during the last six months. In all cases where posts were offered at less than the B.M.A. minimum the Federation had written to the women candidates urging them to retire. It was a matter of great satisfaction that of the women who had accepted such posts not one was a member of the Federation. The Loan Fund of the Federation continues to prove of great use to members Sincere thanks were tendered to Dr. Christine Murrell for establishing a new fund, the John Rains Memorial Loan Fund, in memory of her grandfather, Mr. John Rains, and of his active interest in the education of medical women. It will be subject to the same regulations as the Federation Loan Fund, its object being to make loans to medical women, especially to those starting in practice.

A meeting of the London Association of the Federation was held on Nov. 9th, Miss Elizabeth Bolton, the President, being in the chair. Miss Ida C. Mann read a paper on Routine Examination of the Eyes as an aid to Diagnosis. She emphasized the importance of routine examination of the eyes, including an ophthalmoscopic examination. The cases of ocular disease which most often came in the first instance to the general practitioner, and would be discovered by the routine tests, fell into two groups—namely, (1) those who complained of ocular symptoms and nothing else, and (2) those who complained of other symptoms and made no mention of their eyes. Errors of refraction might cause not only headache but feelings of depression, lack of concentration, fatigue, anxiety, and even, in some cases, nausea and dyspepsia. A suitable pair of glasses would do a hypermetropic clerical worker more good than a month's holiday and might often avert a definite breakdown. Even more important than the detection of errors of refraction was the early diagnosis of glaucoma. This was, of course, not actually a matter for the general practitioner, but the disease could at least be suspected. Miss Mann pointed out the danger of injections of atropin before operation in a subject of chronic glaucoma, and quoted six cases which had been treated for gastric influenza, intestinal colic, food poisoning, and other troubles, before advice was sought for the ocular condition. The communication was discussed by Dr. N. E. Dalby, Dr. E. Casson, Dr. A. Sheppard, Dr. R. Ford.

RONTGEN SOCIETY.—A general meeting of this society will be held on Tuesday, Dec. 7th, at 8.15 P.M., in the British Institute of Radiology, 32, Welbeck-street, London, W. Mr. Cuthbert Andrews will demonstrate the Seriascope, a new instrument for serial radiography, and Mr. W. V. Mayneord will give a paper on Crystal Structure.

INCOME-TAX ALLOWANCE FOR THE DOCTOR'S CAR.—On the question of income-tax allowances to a medical man in respect of his car, Lord Decies writes to point out that the allowance for wear and tear which had been granted to traders in respect of plant and machinery was extended to professions as from April, 1925, thus of course including all medical men. The allowance is one of approximately 10 per cent. on the current value of the car. Previously the only method of claim was by way of renewals and repairs, but the Income Taxpayers' Society, moving through its Parliamentary Committee, was instrumental in bringing about the change to the present system.

WEST KENT MEDICO-CHIRURGICAL SOCIETY.—At a meeting of this society held on Nov. 12th at the Miller General Hospital, Greenwich, Dr. H. Nockolds, the President, took the chair, and Mr. Harold Chapple gave an address on Abdominal Pain in Women. A group of women, he said, complained of pain after parturition. There were three tender spots, the sacro-iliac joints (right and left) and the lumbo-sacral joint. Pregnancy caused softening of the ligaments. The symphysis tended to be jammed down, and movement caused pain. Abdominal and lumbar exercises should be ordered after pregnancy and, if the pain persisted, forcible movement under an anæsthetic was required. Pain in the left iliac fossa was common, said Mr. Chapple, and pressure on the pelvic colon caused pain. Bands developed and fixed the colon, after which further bands produced rotation of the bowel on its long axis so that partial obstruction might follow. Abdominal operation was needed to free the bowel and constipation must be avoided. Frequently the ovary was caught with the bowel and dysmenorrhœa developed. The bursting of the Graafian follicle caused pain in these cases. A number of members joined in the discussion.

A PROPOSED CENTRAL INFORMATION BUREAU.—Sir Richard Gregory writes on behalf of the Council of the Association of Special Libraries and Information Bureaux: "As a result of successful conferences which have been held annually for the past three years the Association has been formed and is now in process of incorporation. The Council cordially invites the support of all organisations and bodies, commercial houses, industrial concerns, &c., which attach adequate importance to the collection, treatment, and dissemination of information relevant to their work. The new body will act as a channel through which any inquiring member may be put into direct touch with the source of information required. With the generous assistance of the Carnegie Trust the Association has in preparation a Directory of sources of specialised information in the British Isles; a copy of this will be sent free to each member, as soon as available. In addition it is hoped to establish by coöperation between interested parties, unified policies with respect to abstracting, cataloguing, indexing, and filing."

Membership of the Association is open to all interested bodies. The subscription has been fixed at £2 2*s*. per annum, and to ensure the establishment of a clearing house on an adequate scale not less than 500 members are required by March, 1927. Further details, including a form of application and a list of members will be furnished by the Secretary, 38, Bloomsbury-square, London, W.C. 1.

ROYAL MEDICAL BENEVOLENT FUND.—At the last meeting of the Committee 40 cases were considered and £440 was voted to 31 applicants. The following is a summary of some of the cases relieved:—

Daughter, aged 66, of L.R.C.S. who died in 1883. When able to work made about 25*s*. a week teaching. Has not been strong since an attack of influenza two years ago, and is now unable to work. A friend left her £42 per annum and she received £16 from a relative. Her rent is 6*s*. a week. Voted £18 in 12 monthly instalments.

Widow, aged 58, of L.R.C.P. Was a clerk until Christmas, 1924, when she was discharged and has found it very difficult to get a post since that time. Late husband was an annuitant of the Fund. Applicant receives £52 from the rent of a house less interest on mortgage and ground rent and repairs. Voted £5 while seeking employment.

Daughter, aged 53, of M.D. St. And. who died in 1913. Has maintained herself by taking temporary posts as a clerk, and owing to recent illness has asked the Fund for further assistance. She has an annuity of £40 per annum. Rent and gas amount to £44 per annum. Private typewriting and clerical work brought her in about £78. Relieved twice, £17 10*s*.; voted £12 in 12 monthly instalments.

Subscriptions may be sent to the Honorary Treasurer, Sir Charters Symonds, K.B.E., C.B., at 11, Chandos-street, Cavendish-square, London, W. 1.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

Anti-Vivisection Petition.

Mr. LANSBURY presented a petition in the House of Commons on Tuesday, Nov. 23rd, signed by residents of the Wood Green, Hammersmith, and Lewisham districts praying that the House would pass a Bill withdrawing the sanction of the law from the practice of vivisection.

HOUSE OF LORDS.

THURSDAY, NOV. 18TH.

LEAD PAINT POISONING BILL.

THE House went into Committee on the Lead Paint (Protection Against Poisoning) Bill, the Earl of DONOUGHMORE in the chair.

Lord ARNOLD moved to insert before Clause 1 a new clause prohibiting the use of lead paint in painting the interior of buildings, except in the case of buildings which were excluded from the provisions of the section by an Order of the Secretary of State made after consultation with the organisations, if any, representative of the employers and workers; or painting with lead paint for artistic purposes, or the process of fine lining in such circumstances or in accordance with such conditions as might be prescribed. He said that he held that there was the strongest case for this new clause. It was admitted by the Government that the use of lead paint did lead to serious consequences. Statistics showed that every year some hundreds of men suffered from lead paint poisoning and from 40 to 50 men died every year from its effects. Since he had spoken a week previously the Home Secretary, in reply to a question in the House of Commons, had admitted that this year in the case of one firm in the Potteries there had been three cases of lead poisoning and that one case had proved fatal. The right hon. gentleman admitted that it was a bad case, but he said in effect that the regulations in regard to the system of exhaust ventilation had not been maintained in an efficient state. That was just the point which he (Lord ARNOLD) wished to make. They could not with sufficient effectiveness regulate these matters. Certainly they could not do it in regard to interior painting. He submitted that they ought not to "experiment"—to use the word of the Home Secretary—in a matter of this kind, particularly as doing so involved a breach of faith in respect of the Geneva Convention of 1921.

The Bishop of SOUTHWARK said he hoped very much that the Government would see their way to accept this amendment. He could not see how these Regulations were going to be carried into effect. It was not a matter in regard to which they could safely delay and wait to see how the Regulations worked. They were dealing with human lives and human suffering, and every year they delayed in dealing with this matter effectively added to the sum total of human suffering which could be prevented.

Lord DESBOROUGH said that he regretted that the Government could not possibly accept this new clause. Their lordships knew perfectly well that it was not generally acceptable. Canada was against it and also Australia and South Africa. A committee of experts who considered the whole position with the help of a medical subcommittee really preferred in their own minds a system of regulation rather than total prohibition of lead painting for inside work. If an important change of this character were introduced into the Bill there was not the smallest prospect, having regard to the other legislation which had to be dealt with, that the measure would become law. The Government believed that the desired object could be achieved by regulations. If experience proved the regulations to be insufficient the Government would then be quite prepared to bring in another Bill to deal with the matter.

Earl BEAUCHAMP supported the new clause.

The proposed new clause was negatived by 45 votes to 23.

On Clause 2 (which deals with the prohibition of the employment of women and young persons in painting buildings with lead paint),

Lord BALFOUR OF BURLEIGH moved an amendment to exclude women from the prohibition. He said that he supposed that the Government would rest their case for prohibition on medical grounds. The medical case for prohibition, he believed, rested partly on theory and partly on fact. The theory was that women were more susceptible to lead poisoning than men. He believed that that theory dated from the period when women were engaged, particularly in the Potteries, in very dangerous processes in connexion with lead. The women were on the whole very poorly paid and therefore there were predisposing causes leading to lead poisoning. That theory had become fossilised and crystallised on all subsequent legislation on the point. He did not think that any special inquiry had taken place since women were excluded by regulation in the case of the Potteries. The second point with regard to women was the undoubted fact that in their case lead poisoning led to great racial misfortune as far as the family was concerned. They were very much more likely to have miscarriages and still-births than healthy women, and this fact standing by itself was a good reason for exclusion, but it did not take any cognisance of the other fact that the suffering of the father from lead poisoning produced precisely the same effect. A good many foreign investigators had come to the conclusion that paternal lead poisoning was just as serious from the racial point of view as maternal lead poisoning. Apart from the medical side of the case, if prohibition was applied to women the Government were playing straight into the hands of one of the most powerful vested interests which existed—the trade-unions.

Lord DAWSON said he agreed that there was a prima facie objection to differentiation between the sexes and the onus of proof lay upon those who sought to impose differentiation. He doubted if that case existed, or at any rate if it existed sufficiently proved to justify prohibition. There was a further reason—namely, that it was a serious matter in any way to hinder women in seeking employment where they were able to engage in it. One of the most striking features of the last 50 years was the way in which woman had shown her aptitude in working out her own destiny. She had shown a sureness of touch in extending her activities from one sphere to another, and had widened her outlook in the main with striking success. He would place far more reliance upon the women themselves in deciding whether they should undertake the painting industry or not than on any Regulations. There were a great many occupations which women were precluded from undertaking on account of the fact that they were physically weaker than men. It was, therefore, the more important to give them every opportunity of entering skilled trades for which they were physically suitable; and the painting industry was one of those. They were strong enough to undertake it, the conditions were suitable, unless it could be proved that they were specially prone to the poison of lead. The question, therefore, was: Is the case proved that the proclivity of women is so marked, as compared with men, that it is necessary to prohibit them from taking part in this industry? He freely admitted that if they took the figures at present available there was very striking evidence that lead attacked women, especially young women, more often and with greater severity than men. But those figures were mainly taken from the old days in the Potteries, days which in a great measures were past. In those days the women to a large extent undertook the less skilled, the more dangerous forms of work. They were economically in a less fortunate position, and they were less protected; and there was certainly ground for the view that a large part of that proclivity of women was the result of their economic position rather than of their sex characteristics. At any rate, he would put it as high as this, that unless a further inquiry was undertaken in the light of modern knowledge he would doubt very much whether there was a case for excluding women from the painting trade. The next point was that it had now been established that far and away the most important route for the lead poison to enter the system was by the respiratory tract. The effects of dirty fingers and unclean mouths were indirect: they lowered nutrition, they made the people unhealthy, they lowered their resisting power. But, compared with the respiratory tract, these were relatively unimportant routes for the entry of the lead. If Clause 1 of this Bill, as proposed by the Government, was efficient in its working, and if it was true that by these Regulations, by substituting, that was, wet methods for dry methods, they could eliminate the dust, he thought it was quite likely that the greater proclivity of women would fall very nearly to zero. At any rate, he did not think it was safe to use figures and statistics from the days when the lead industry was not properly regulated. With regard to the very important question of pregnancy, it was quite true that lead was a dangerous poison, in that it produced abortion and miscarriages. But, here again, he thought that the women were quite capable of protecting themselves. If the Regulations under Clause 1 were adequate, if, in other words, dust was prevented—and it was dust that mattered and dust only: that was hardly too strong a statement—if the dust was prevented from entering the respiratory tract of these women they would not abort; and therefore if the measures were efficient the miscarriages would not take place. There was the further point referred to by Lord Balfour of Burleigh, that the lead poisoning, in bringing about miscarriages, very often went through the male as well as the female. The figures were most interesting as well as tragic. For example, there was one set of figures affecting workers in lead mines, where the wives had never worked in the lead mines and the men did work in the lead mines, and 40 per cent. of a given block of pregnancies

miscarried. There they had the poison carried by means of the man. And there were other figures bearing that out. Therefore, if they excluded the women and left the men and their Regulations were bad, they would still have miscarriages. If the Regulations were good—and he believed they were good—they would find that women and men would be protected alike. And the women's trade unions would see to it that the women were protected just as the men's trade unions would see to it that the men were protected. He would call their lordships' attention to Clause 1 of the Bill where the Secretary of State was able to order a medical examination. That got over many of the difficulties, because a medical examination would often discover the early stages of lead poisoning before the sufferer had any symptoms at all. And if in future, as he hoped, through the activities of the Industrial Research Council, a means was found whereby, by some biochemical test, they could say who was prone to lead poisoning and who was not, that would probably be a solution of this problem. The point must be borne in mind that there were a large number of people who could breathe lead with apparent impunity, just as there were large numbers of people who could drink alcohol with comparative impunity, and there were others who after a fortnight's work on lead were apt to be poisoned. Therefore, his suggestion was that the prohibition of women should be withdrawn from the Bill, that it should be left to the option of the Secretary of State to regulate whether they should take part in the industry or not, and he thought the suggestion was a good one that the whole question should go to the Industrial Research Council in the hope of finding a biochemical test whereby they might know whether people were prone or not. If these measures were carried out he thought it would meet all the conditions of the case and meet what to his mind was a great drawback—namely, differential legislation as between men and women.

Lord BANBURY supported the amendment.

Viscount HALDANE said Lord Dawson of Penn had pointed out the very unsatisfactory character of the *ex cathedra* replies that were given off-hand by medical authorities on a question like this. The effect of plumbism could only be ascertained by careful observation in hospitals and by other means, and by careful observation by qualified observers. He felt quite incapable of forming an opinion whether women were in greater danger of lead poisoning than men and of attaching any importance to authorities quoted either in their lordships' House or in the House of Commons. It was a question that needed careful inquiry, and the Government had two bodies—the Medical Research Committee and the Committee on Civil Research—which they could ask to conduct that inquiry.

Lord DESBOROUGH said that for the last 35 years in every Bill dealing with those industries in which lead poisoning was possible the employment of women and children had always been excluded. Noble lords were proposing something quite new. He was quite ready to admit that medical men were not agreed upon this matter. He had known very few cases in which doctors were absolutely agreed, but he thought that the balance of medical opinion was overwhelmingly on the side of the views which were the basis of the policy adopted by successive Governments for the last 35 years. He was sure that Lord Dawson of Penn would agree that these were authorities on this particular matter second to none in this or any other country. They had devoted their lives to the matter. Lead poisoning was a thing rather outside the purview of the ordinary practitioner and ought to be relegated to those who made an absolute speciality professionally of the question. The authorities were Sir Thomas Oliver and Sir Thomas Legge, the Senior Medical Inspector of Factories. This was the opinion of Sir Thomas Oliver: "On the whole, females, particularly young females, suffer more severely from plumbism than males." Sir Thomas Oliver also said: "My contention is that it is largely owing to the power of lead to inflict harm upon the reproductive organs of women that the female sex is so liable to be adversely influenced by the metal." Later on he said: "An interesting point in regard to maternity and plumbism is that while the expectant mother does not show any sign of plumbism and is apparently not suffering from lead poisoning, she transmits to her babe such a legacy of lead that the infant is born dead or dies shortly after birth." In his book on lead poisoning and lead absorption, which was written in conjunction with Sir Kenneth Goadby—also, he believed, an admitted authority—another well-known expert, Sir Thomas Legge, stated unequivocally that women were more susceptible to poisoning by lead than men. The question of lead poisoning was reviewed by a special commission on unhealthy processes appointed by the First International Labour Conference which met at Washington in 1919. There was a great gathering of experts, including a number from the chief industrial countries of Europe. In their report they stated: "What is then the general principle which should be applied in the case of women? That arrived at is one which will probably commend itself to all—namely, only when interference with the function of maternity can be shown to exist, should women's employment be made a bar and lead has been proved medically to be the chief, if not the only, intoxicant, in which this danger is present."

Lord PHILLIMORE supported the amendment.

The amendment was negatived by 35 votes to 17.

The remaining clauses were agreed to and the Bill was reported without amendment to the House.

HOUSE OF COMMONS.

WEDNESDAY, NOV. 17TH.

Guardians and Hospital Treatment.

Mr. WALTER BAKER asked the Minister of Health whether he was aware that the seat of a member of the Bristol board of guardians had been declared vacant because she received treatment following a motor accident in the vicinity of that institution; that it was impossible to remove the patient owing to the serious nature of the injuries, and that the cost of maintenance as a private patient was repaid in addition to the specialist's fees; and whether he was in a position to give an assurance that this special type of disqualification should be dealt with in the measure of Poor-law reform which he proposed to introduce during 1927.—Sir KINGSLEY WOOD (Parliamentary Secretary to the Ministry of Health) replied: My right hon. friend is aware of this case which presents a striking illustration of the anomalies prevailing under the existing law. He is not in a position to say when amending legislation will be introduced, but this matter should certainly receive attention whenever such legislation is considered.

Poor-law Reform.

Mr. SCURR asked the Minister of Health whether he proposed to introduce the Poor-law Reform Bill this session.—Sir KINGSLEY WOOD replied in the negative.

Mental Defective Charged with Attempted Murder.

Colonel DAY asked the Minister of Health whether his attention had been drawn to the charge of attempted murder against Reginald Farndale, aged 11 years, at Chester; and, as this lad was certified as a mental defective three years ago, would he state what action had been taken with a view to providing accommodation for such cases.—Mr. NEVILLE CHAMBERLAIN replied: My attention has been drawn to this case and I am informed that accommodation has been found for the lad in an institution in Gloucestershire. Unfortunately, there is at present a shortage of accommodation for mental defectives throughout the country; and local authorities are being urged to make further provision. The local authorities in the county of Cheshire are now considering a proposal to provide a joint institution to serve the whole county.

The Purity of White Bread.

Rear-Admiral BEAMISH asked the Minister of Health whether he was prepared to make an official pronouncement on the purity of white bread and thus allay the doubts concerning an article of food which was eaten by over 95 per cent. of the population; and whether he will instruct the departmental committee which was examining the question of flour treatment to extend its inquiries with a view to making an authoritative statement on the dietetic value of the people's staple foodstuff.—Mr. NEVILLE CHAMBERLAIN replied: This subject is referred to in a report entitled "Diet in Relation to Normal Nutrition," which was issued by my department a few years ago. I will consider whether it is desirable to extend the terms of reference of the departmental committee, but I am informed that they could not take up the subject referred to in the question until they have disposed of their present reference.

Ventilation on H.M. Ships and Tuberculosis.

Sir BERTRAM FALLE asked the Parliamentary Secretary to the Admiralty whether in view of the incidence of tuberculosis among ratings of the Royal Navy, he would institute an inquiry into whether the ventilating arrangements in living spaces below armour in His Majesty's ships were satisfactory; and whether the regulations laid down for the artificial ventilation of living spaces were properly observed.—Mr. BRIDGEMAN replied: The ventilating arrangements of H.M. ships are the subject of the most careful consideration in every case. The general principles to be followed when fitting the ships were settled by a representative committee a few years ago, and those principles are properly observed when settling details. Moreover, any representations from H.M. ships as to possible improvements in ventilation are considered and acted upon as far as possible. With regard to the last part of the question the necessity of this is considered so important that it is specially reported on by flag officers

at their inspection and a special inquiry is not considered necessary. I may add that I do not agree with the implied suggestion of my hon. friend that the incidence of tuberculosis in the Navy is exceptional.

Malaria in India.

Colonel DAY asked the Under Secretary of State for India what action was being taken by the Government of India with a view to abating malaria.—Earl WINTERTON replied: Public health being a transferred subject, antimalarial measures are a matter for the Provincial Governments except in regard to the health of the army and to central agencies and institutions for research. The measures undertaken include the destruction of breeding places of mosquitoes by oiling and drainage, &c., the prohibition of rice cultivation near certain towns, jungle cutting, propaganda work, the formation of antimalarial [coöperative societies, and the systematic distribution of quinine at low prices. At the same time the area under *cinchona* cultivation is being steadily increased with the object of making India self-supporting in the matter of quinine.

FRIDAY, NOV. 19TH.

LONDON UNIVERSITY BILL.

On the order for the second reading of the University of London Bill, which has already passed through the House of Lords,

Lord EUSTACE PERCY (President of the Board of Education) explained that the object of the measure was to appoint Statutory Commissioners to draw up statutes for the University of London in general accordance with the report of the departmental committee appointed by his predecessor, Mr. Trevelyan. The Bill followed the lines of the Oxford and Cambridge measures. The departmental committee in their report pointed out that the University had practically no financial resources which it could devote to the development of its teaching or research except the balance of examination fees, and yet the total income for the year 1923–24 of the 22 schools at the University in receipt of grants from the Treasury, including the incorporated colleges, amounted to nearly £1,000,000, of which about £360,000 represented recurrent grants from the University Grants Committee, and about £70,000 from the London County Council. The committee defined the object of their recommendations as follows: "We hope to enable the University Grants Committee, the London County Council, and other present or prospective grant-giving bodies to deal with a central University body as to the needs of the University and its colleges, and to make block grants to the University on the basis of such needs. It is fundamentally inconsistent with the idea of a self-governing university that it should not have sufficient financial resources and authority to initiate and pursue a policy of well-balanced development, and to prevent wasteful duplication and competition." While all were agreed, Lord E. Percy continued, that the financial impotence of the University of London, alone among all the universities of the country was an undesirable thing, yet so far as he knew there was no section of opinion in the University of London, and no one connected with it in any way, prepared to accept the present supreme governing body of the University—the Senate as at present constituted—as the authority for allocating grants from public bodies. The University of London had grown as Englishmen liked institutions to grow, on no fixed lines, developing to meet national needs as they arose without any preconceived principle of organisation. That character of the University ought to be preserved and there should be no question of standardising the University of London according to preconceived ideas or analogies with other universities. The departmental committee, broadly speaking, limited its main recommendations to two things. In the first place the committee proposed so to modify the present constitution of the Senate as to give representation on the Senate to the constituent schools of the University, who with the exception of King's College and University College, had no representation as such on the governing body. The second proposal of the committee was the establishment of a new finance council to deal with all questions of finance.

Dealing with criticism of the proposals of the Bill, Lord E. Percy said that it was alleged that the Board of Education had hitherto had nothing to do with the University and that this was a means of establishing Board of Education control over the University. As a matter of fact, the Board of Education had nothing to do with the Bill and would have nothing to do with the University statutes, or with the University, after the statutes were passed. It was well understood that the relations between the Government and the universities should be entirely in the hands of the Privy Council and that would be the position under this Bill. The second criticism related to the number of appointees of the Crown and of local authorities on the proposed new finance council. At present the Crown appointed four representatives on the Senate and the London County Council appointed two. That made six representatives in a total Senate of 26. It was proposed that the Crown and the London County Council should nô longer be represented on the Senate, but that those six members should be transferred to the council of 16 members. He agreed with the principle that the Crown and the public authorities should not in exchange for their grants exercise any control over University policy. But the reason for the proposed Crown representation was this: practically the whole of the finance of the University of London was at present in the hands of no university and no college body. It was in the hands of the University Grants Committee, a purely departmental, and if they liked, bureaucratic organisation. The reason for this Bill was to get rid of that undesirable control, and to hand over the allocation of Government money to a university body. It was desirable that the financial administration of a university should be carried out very largely with the assistance of elements outside the university competent in matters of business administration and finance. In London it was far more difficult to get a natural local business element on the council of the University than it was in provincial centres, and the sole object of Crown representation was not to retain any control for the Government over the allocation of grants, but to get in the most efficient way the most eminent men to supply that outside independent element. A third criticism related to the elimination of what was commonly known as the nominated third on the Senate. He recognised that that nominated third had done excellent work in the past, and was capable of doing excellent work. Its elimination was really due to the hard facts of the case. If it were true that they should not interfere with the representation of the graduates or the faculties on the governing body and on the Senate, and if it were true that they should in the University of London secure some organic representation of the schools of the University as such, they could not include that in the miscellaneous element in the Senate without making it so large a body as to be absolutely unworkable. It was only by chance that the nominated third did represent the outside independent element. It was constituted, for instance, of representatives from the Royal College of Surgeons and the Royal College of Medicine. At the present moment there was no representation of the medical schools in the University at all, but the Royal College of Surgeons and the Royal College of Medicine were there at the present moment far more as representatives of the medical schools than as representing outsiders. The same was true of the Incorporated Law Society and the Inns of Court. Finally, the City and Guilds Institute was there now far more as representing the Imperial College of Science than any general body of business opinion or interests. Therefore, the answer to the criticism with regard to the nominated third was that they could not get any proper organic representation of the schools of the University without eliminating some element, and moreover, the functions of the nominated third would be better secured by getting organic representation of the constituent schools on the Senate and by leaving the outside element to the council.

Mr. TREVELYAN (President of the Board of Education in the Labour Government) said that the Labour Party supported the Bill and hoped that it would become law this year.

Dr. LITTLE, the Member for the University, moved the rejection of the Bill. He said he was elected because he took up a position of opposition to the reconstitution of the University on the lines suggested by the Haldane Report. Those who opposed the Bill objected to it in the first place on the ground of its interference with the independence of the schools of the University. The schools were strong institutions having traditions of very many years and even of centuries. They were very largely financially independent and many of them would prefer to renounce grants altogether rather than receive grants on condition that their independence was taken away. The colleges had already raised a warning note against the proposed reconstitution, and he begged the House to have regard to what might happen to a university which was the largest in the world which was likely to be put into a position when its component schools, which were its glory, might depart from it. It was of great importance also to the University to maintain the Imperial link which could only be done by the external examinations. The grants that were proposed to be given constituted little more than a third of the revenue of the University, but the grant-giving bodies would control not only the application of the grants which they gave themselves, but all the funds of the University. He denied that the University of London was unwilling to accept changes, but they contended that it was better that changes should come by agreement, and to force a solution on the University would not be worthy of the House of Commons.

After further discussion the motion for the rejection of the Bill was negatived without a division, and the Bill was read a second time.

The money resolution in connexion with the Bill was also agreed to in Committee.

Encephalomyelitis after Vaccination.

Mr. GROVES asked the Minister of Health whether he had drawn the attention of the Committee on Vaccination, now sitting, to the cases of death from encephalomyelitis after vaccination; and whether he would direct the Committee to make an investigation into the whole question of the risk of spreading encephalomyelitis and other kindred diseases which appeared to be associated with the practice of vaccination.—Mr. NEVILLE CHAMBERLAIN replied: The answer to the first part of the question is in the affirmative. As regards the second part, one of the terms of reference of this Committee is to inquire into and report on the practical methods which are available in the light of modern knowledge to diminish or remove any risks which may result from vaccination.

Mr. TREVELYAN THOMSON asked the Minister of Health whether encephalomyelitis was mentioned as a cause of death on the certificates of death in the case of the seven deaths from that disease which occurred shortly after vaccination; whether an inquest was held on any of the cases in question; and whether the lymph used for the vaccinations was issued by his Department.—Mr. NEVILLE CHAMBERLAIN replied: I assume that the hon. Member is referring to seven cases recently discussed in the medical press, and I am informed that, so far as it has been possible to identify these fatalities, in none of the seven deaths was "encephalomyelitis" mentioned on the practitioner's certificate as a cause of death. An inquest was held in one case. In 4 of the 7 cases the lymph used for the vaccination was issued by my Department, and in one instance a proprietary lymph was used, but no information as to the source of the lymph used in the remaining two cases is now available. I may remind the hon. Member that these deaths occurred in 1912, 1922, and 1923.

MONDAY, NOV. 22ND.

Disease in Nigeria.

Viscount SANDON asked the Secretary of State for the Colonies what steps the Government of Nigeria were taking to deal with the critical health and mortality situation as indicated in the annual report.—Mr. AMERY replied: The Nigerian Government is taking every possible step to deal with the outbreaks of disease referred to in the report, which is for the year 1925. I am given to understand that the severe epidemics in the Northern Provinces did not recur in 1926. As regards plague in the Southern Provinces, a special visit was paid to Nigeria by Sir Edward Thornton, of the Union of South Africa, and as a result an energetic campaign has been undertaken with the aid of personnel borrowed from the Army. Thirty-one medical officers have been appointed to Nigeria since January, 1925, and the medical and sanitary departments have been expanded, and will be further enlarged. It is not correct to describe the situation as critical. In a country so large as Nigeria it is quite impossible to prevent the introduction of epidemic disease from time to time.

Condensed Skim Milk as Infants' Food.

Viscountess ASTOR asked the Minister of Health whether he was aware that the importation of condensed skim milk was prohibited in Cuba, the Bahamas, Chile, Argentine, British Honduras, British East Africa, the Straits Settlements, Italy, and other countries; and why he considered that it was not practicable to take similar steps to prevent the sale in this country of a product which he recognised to be unfit for babies.—Sir KINGSLEY WOOD replied: My right hon. friend is aware that the importation of condensed skimmed milk is prohibited in some countries. He is advised that though the absence of fat renders this article unfit for feeding babies, it is not unsuitable for other purposes. Containers in which condensed skim milk is sold are at present required to bear the label "unfit for babies," and from the point of view of the public health he sees no grounds so long as this warning is given, for prohibiting its importation into this country.

Viscountess ASTOR asked if the hon. gentleman would bear in mind that many Medical Officers of Health had reported that the labelling was quite inadequate as a means of ensuring that this condensed milk was not used for babies, and would it not be possible to get a more prominent label, as this was a real danger in many parts of the country.

Sir KINGSLEY WOOD said he would look into the question of the labelling and see what could be done.

Infantile Paralysis among Schoolboys.

Viscount SANDON asked the Minister of Health, in order to obviate the danger of infantile paralysis being spread by reason of boys being withdrawn from infected schools by parents, if he would take steps to prevent any school so infected from being closed down or the boys leaving.—Mr. NEVILLE CHAMBERLAIN replied: I am not empowered to take the course suggested, but I am always ready to arrange for the medical officers of my Department to confer with the school authorities as to the precautions appropriate to any outbreak of infectious disease.

TUESDAY, NOV. 23RD.

Hospitals and Coal Priority.

Col. LANE-FOX (Secretary for Mines) stated in reply to Mr. Briant that on the list of priority consumers of coal, hospitals, workhouses, and similar institutions stood first, and manufacturers of drugs and medicines last.

Segregation of Children from Mental Defectives.

Mr. DAY asked the Minister of Health what action had been taken by the Walsingham, Norfolk, board of guardians, following the visit of Inspector Bushell, to segregate children from mental defectives.—Sir KINGSLEY WOOD replied: All children over three years of age have now been removed from this institution; the only mentally deficient persons associating with the children in the institution are the mothers of those children.

Medical Diary.

Information to be included in this column should reach us in proper form on Tuesday, and cannot appear if it reaches us later than the first post on Wednesday morning.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

WEDNESDAY, Dec. 1st.—5.30 P.M., TROPICAL DISEASES AND PARASITOLOGY. Papers: Dr. R. T. Leiper: Tyranny of Nomenclatural Rules in Medicine. Dr. S. V. van Nierkerk: Hermaphroditism in Native Labourers in Johannesburg. Miss I. Hiles: Serological Tests in the Diagnosis of Hydatid Cyst. Dr. M. A. Azim: Coccidium in White Rats in England (communicated by Dr. J. Gordon Thomson). Dr. W. Broughton-Alcock: A Spirochætic Infection with Neuroses and Perforation of the Ileum. 8.30 P.M., SURGERY. Discussion: The Treatment of Gangrene of the Extremities. Opener: Prof. G. E. Gask. Mr. Sampson Handley will follow.

FRIDAY.—5 P.M., LARYNGOLOGY. Cases and specimens will be shown at 4 P.M. by Dr. Andrew Wylie (President), Mr. Frank Rose, Mr. Norman Patterson, and others. 8.30 P.M., ANÆSTHETICS. 8.15 P.M., OTOLOGY, MEDICINE, AND NEUROLOGY. Special Discussion: The Relation of Abnormalities of the Blood Pressure to Diseases of the Ear, to be opened by Sir William Milligan, followed by Dr. Lewis Smith (for the Section of Medicine), Dr. W. J. Adie (for the Section of Neurology), Mr. G. J. Jenkins (for the Section of Otology.)

SATURDAY.—10.30 A.M., OTOLOGY. Cases and specimens will be shown at 9.45 A.M. by Mr. Philip Franklin, Mr. Leslie Powell, Mr. Banks-Davies, and others. Papers: Mr. George Wilkinson: Have We a Resonance Theory of Hearing, or only a Resonance Hypothesis? Sir James Dundas-Grant: Remarks on the Use of Weber-Liel's Intratympanic Tube in Chronic Eustachian Catarrh.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, W.

MONDAY, Nov. 29th, to SATURDAY, Dec. 4th.—FELLOWSHIP OF MEDICINE. Special lecture at the Medical Society, 11, Chandos-street, Cavendish-square, W. Thurs., Dec. 2nd, at 5 P.M., Dr. John Parkinson: Cardiac Emergencies. Free to members of the medical profession. —ROYAL WATERLOO HOSPITAL, Waterloo-road, S.E. Special course in medicine, surgery, and gynæcology. —ST. JOHN'S HOSPITAL, Leicester-square, W.C. Special course in Dermatology.—WEST END HOSPITAL FOR NERVOUS DISEASES, 73, Welbeck-street, W. Late afternoon course (5 P.M.) demonstrations upon selected cases. Further information from the Secretary of the Fellowship of Medicine.

UNIVERSITY COLLEGE, Gower-street, W.C.

WEDNESDAY, Nov. 24th.—5 P.M., Dr. C. H. Best: Insulin. (Third of four advanced lectures in Physiology.)

POST-GRADUATE HOSTEL, Imperial Hotel, Russell-square, W.C.

TUESDAY, Nov. 30th.—9 P.M., Mr. W. E. Miles: Fistula.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.

MONDAY, Nov. 29th.—10 A.M., Surgical Clinic. 2 P.M., Medical Cases in the Wards. 2.30 P.M. to 5 P.M., Medical, Surgical, and Gynæcological Clinics. Operations.

TUESDAY.—2.30 P.M. to 5 P.M., Medical, Surgical, Throat, Nose, and Ear Clinics. Operations.

WEDNESDAY.—2.30 P.M. to 5 P.M., Medical Skin and Eye Clinics. Operations.

THURSDAY.—11.30 A.M., Dental Clinic. 2.30 P.M. to 5 P.M., Medical, Surgical, and Ear, Nose, and Throat Clinics. Operations.
FRIDAY.—10.30 A.M., Throat, Nose, and Ear Clinics. 2.30 P.M. to 5 P.M., Surgical, Medical, and Children's Diseases Clinics. Operations.
On Monday, Nov. 29th, and Friday, Dec. 3rd, at 2.30 P.M., there will be special demonstrations of Surgical and Medical (Children) Cases by Mr. H. W. Carson and Dr. Bruce Williamson respectively.

WEST LONDON POST-GRADUATE COLLEGE, West London Hospital, Hammersmith, W.
MONDAY, Nov. 29th.—10 A.M., Mr. Macdonald: Genito-Urinary Operations. 12 noon, Mr. Simmonds; Fractures and Applied Anatomy. 2 P.M., Dr. Scott Pinchin: Medical Out-patients.
TUESDAY.—12 noon, Dr. Burrell: Demonstrations of Chest Cases. 2 P.M., Mr. Addison: Operations. 2 P.M., Mr. Sinclair: Surgical Out-patients.
WEDNESDAY, Dec. 1st.—10.30 A.M., Dr. Burnford: Medical Wards. 2.30 P.M., Mr. Donald Armour: Surgical Wards. 2 P.M., Dr. Owen: Medical Out-patients.
THURSDAY.—10 A.M., Dr. Grainger Stewart: Neurological Dept. 2 P.M., Mr. Simmonds: Surgical Out-patients. 2 P.M., Mr. Bishop Harman: Eye Dept.
FRIDAY.—10 A.M., Sir Henry Simson: Gynæcological Operations. 10.30 A.M., Dr. Dowling: Skin Dept. 2 P.M., Mr. Vlasto: Throat, Nose and Ear Dept.
SATURDAY.—9.30 A.M., Dr. Burnford: Bacterial Therapy Dept. 10 A.M., Dr. Saunders: Medical Diseases of Children.
Operations, Medical and Surgical Out-patients, Special Departments, daily, 10 A.M. to 5 P.M., Saturdays, 10 A.M. to 1 P.M.

CENTRAL LONDON THROAT, NOSE, AND EAR HOSPITAL, Gray's Inn-road, W.C.
FRIDAY, Dec. 3rd.—4 P.M., Mr. Archer Ryland: Demonstration of Some Museum Specimens.

HOSPITAL FOR SICK CHILDREN, Great Ormond-street.
THURSDAY, Dec. 2nd.—4 P.M., Dr. Theodore Thompson: Encephalitis in Children.

LONDON SCHOOL OF DERMATOLOGY, St. John's Hospital, 49, Leicester-square, W.C.
TUESDAY, Nov. 30th.—5 P.M., Dr. J. H. Sequeira: Tuberculosis Cutis (2).
THURSDAY, Dec. 2nd.—5 P.M., Dr. Haldin-Davis: Acne. Rosacea.

MANCHESTER ROYAL INFIRMARY POST-GRADUATE COURSE.
TUESDAY, Nov. 30th.—4.15 P.M., Mr. F. H. Westmacott: Middle-Ear Suppuration.
FRIDAY.—4.15 P.M., Dr. G. R. Murray: Hypothyroidism and its Treatment.

UNIVERSITY OF SHEFFIELD POST-GRADUATE CLINICS.
FRIDAY, Dec. 3rd.—3.30 P.M., at the Royal Infirmary: Mr. Pooley: Infections of the Lacrymal System.

ROYAL INSTITUTE OF PUBLIC HEALTH, 37, Russell-square, W.C.
WEDNESDAY, Dec. 1st.—4 P.M., Dr. P. C. Varrier-Jones: Settlements for Tuberculous Workers.

CHADWICK PUBLIC LECTURES.
THURSDAY, Dec. 2nd.—8 P.M. (in the Barnes Hall, Royal Society of Medicine), Sir Henry Gauvain: Sun, Sea, and Open Air in Relation to Health.

JAMES MACKENZIE INSTITUTE FOR CLINICAL RESEARCH, St. Andrews.
TUESDAY, Nov. 30th.—4 P.M., Mr. A. Ernest Maylard: The Bearing of Such Conditions as High Blood Pressure, Albuminuria and Glycosuria on the Performance of Surgical Operations. Discussion to be opened by Dr. Norman McLeod.

Appointments.

PICKWORTH, F. A., M.B., B.S. Lond., has been appointed Director to the Research Board for Mental Disease, City and University of Birmingham.

Vacancies.

For further information refer to the advertisement columns.

Birmingham and Midland Eye Hospital.—Two H.S.'s. £120 and £110 respectively.
Brighton, Borough Infectious Disease Hospital and Sanatorium. Res. M.O. £350.
Brighton, Royal Alexandra Hospital for Sick Children.—H.S. At rate of £100.
Brighton, Sussex Maternity and Women's Hospital.—Second Res. H.S. £100. Also Second Hon. Obstet. Phys.
Buxton and District Cottage Hospital.—Aural Surg.
Cambridge, Addenbrooke's Hospital.—H.S. At rate of £130.
Cambridge, Papworth Sanatorium and Village Settlement.—H.P. At rate of £100.
Cancer Hospital, Fulham-road, S.W.—Pathologist. £1000. Also H.S. At rate of £100.
Canterbury City and Borough, &c.—M.O.H. and School M.O. £800.
Charing Cross Hospital, W.C.—Asst. P.
City of London Hospital for Diseases of Heart and Lungs, Victoria Park, E.—Res. M.O. £250. H.P. At rate of £100. M.O. to Out-patient Dept., At rate of £150.
Dublin, Dr. Steevens' Hospital.—Reg. Surg.
Dudley Guest Hospital and Eye Infirmary.—H.S. and Asst. H.S. £175 and £150 respectively.
East African Medical Service.—Two Asst. Bacteriologists. £600.
General Lying-in Hospital, York-road, Lambeth, S.E.—Res. M.O. At rate of £100.
Hampstead General and North-West London Hospital, Haverstock-hill, N.W.—H.S. Also Cas. Surg. O. to Out-patient Dept. Each at rate of £100.
Hospital for Sick Children, Great Ormond-street, W.C.—H.P. and H.S. Each at rate of £50. Also Surg., Phys. to Out-patients. Anæsthetist. £15 15*s.*
Hull Royal Infirmary.—Asst. H.P. At rate of £130.
Infants Hospital, Vincent-square, Westminster.—Med. Ref. £120.
London Homœopathic Hospital.—Three Res. M.O.'s. At rate of £100.
London Hospital, E.—First Asst. and Reg. to one of the five Surgical Firms. £300.
London Lock Hospital, 91, Dean-street, W.—Clin. Assts. to Out-patients.
Lucknow University.—Prof. of Anatomy. Rs.1450 per mensem.
Macclesfield, Cheshire County Mental Hospital, Parkside.—Asst. M.O. £350.
Manchester Royal Infirmary.—Asst. Res. Surg. O. At rate of £150. Also Res. M.O. £200.
Margate, Royal Sea-Bathing Hospital for Surgical Tuberculosis.—Two H.S.'s. At rate of £200.
Melbourne University.—Director of Tubercular Research. £1000.
Mildmay Mission Hospital, Austin-street, Bethnal Green, E.—Sen and Jun. Res. M.O.'s. £140 and £100 respectively.
National Hospital, Queen-square, W.C.—Res. M.O. £200.
Norwich, Norfolk and Norwich Hospital.—H.P. and H.S. Each £120.
Nottinghamshire County Council, &c.—Asst. Sch. M.O. and Dist. M.O.H. £700.
Perth, James Murray's Royal Asylum.—Asst. Phys. £300.
Prince of Wales's General Hospital, N.—Hon. Clin. Assts.
Queen Mary's Hospital for the East-End, Stratford, E.—Res. M.O., H.S.'s., H.P.'s., &c.
Royal Army Medical Corps.—Commissions.
Ruthin Castle, North Wales.—Jun. P. At rate of £200.
Salford Royal Hospital.—Two Hon. Asst. Surgs.
St. John's Hospital, Lewisham, S.E.—Cas. O. At rate of £100.
Swansea General and Eye Hospital, Beck Laboratory.—Asst. Pathologist £500.
University College Hospital, Gower-street, W.C.—Two Clin. Assts. to X Ray Dept.
West Bromwich County Borough.—M.O.H. £1000.
West London Hospital, Hammersmith, W.—Phys. Also H.S., H.P., Res. Asst. Cas. O. and Aural and Ophth. H.S. Each at rate of £100.

The Chief Inspector of Factories announces the following vacant appointments for Certifying Factory Surgeons: Ripponden (Yorks), Earl Shilton (Leicestershire), Denbigh (Denbighshire), and Torrington (Devon).

Births, Marriages, and Deaths.

BIRTHS.

BAXTER.—On Nov. 13th, at Wollaston, Northants, the wife of Stephen E. Baxter, M.R.C.S., L.R.C.P., of a daughter.
COX.—On Nov. 19th, 1926, at 49, West Cliff, Preston, Lancashire, the wife of G. Lissant Cox, M.A., M.D., of a son.
KERR.—On Nov. 12th, at 64, Clarence Gate-gardens, N.W., Gwendolin, the wife of R. A. Kerr, *M.C.*, M.B., F.R.C.S., of a son.
KINGDON.—On Nov. 20th, at Knayton, Thirsk, Yorks, the wife of A. T. L. Kingdon, M.R.C.S., L.R.C.P., of a daughter.
STUTTAFORD.—On Nov. 20th, at Horning, near Wroxham, Norwich, the wife of W. J. E. Stuttaford, *M.C.*, M.R.C.S., L.R.C.P., of a daughter.

DEATHS.

COOPER.—On Nov. 20th, at Orchards-way, Highfield, Southampton, William Frank Cooper, L.R.C.S., L.R.C.P. Edin., aged 61.
JAMESON JOHNSTON.—On Oct. 8th, 1926, at 16, Fitzwilliam-place, Dublin, after a very short illness, George Jameson Johnston, M.A., F.R.S.C.I., late professor of surgery, Royal College of Surgeons, Ireland.
LOWE.—On Nov. 20th, at Lyndhurst-terrace, Weymouth, Charles Henry Lowe, M.R.C.S., late of Burton-on-Trent, aged 77.
LOWER.—On Nov. 20th, at St. Blazey, Cornwall, Nynian Yeo Lower, M.R.C.S., L.R.C.P., late of Presteign, Radnorshire, aged 54.
REID.—On Nov. 17th, at Richmond (Surrey), John Reid, M.A., M.D. Aberd., aged 71.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Comments, and Abstracts.

THE ACTIVATED SLUDGE PROCESS OF SEWAGE TREATMENT.

Abridged from the Chadwick Lecture delivered at Southampton on Oct. 25th, 1926,

BY H. T. CALVERT, D.Sc., F.I.C.

AT an early date imperfect drains were laid with the object of keeping the neighbourhood of dwellings reasonably dry, but the solid waste products of human existence were allowed to accumulate near the dwellings, and it was only when a supply of water became available that the opportunity arose in the more thickly populated districts of swilling the refuse into the drains and thus into the nearest watercourse. This was the first step in rendering the dwellings more cleanly, but the resulting evils of river pollution made it necessary that further steps should be taken. At first there was little or no opposition to this growing pollution, and the general impression seemed to be that the use of rivers was to carry away sewage and trade refuse, but the burden which they were called upon to bear was beyond the power of their purifying ability. In spite of official inquiries matters were allowed to drift from bad to worse, but in 1876, as a result of a Royal Commission, the Rivers Pollution Prevention Act was passed, though it was not until county councils were formed in 1888 that any real progress was made and the necessity for treating sewage before discharge into rivers and streams was brought home to local sanitary authorities.

The Principle of Activation.

All artificial biological methods of sewage treatment—whether by means of contact beds, percolating filters, or activated sludge—are really developments of the "intermittent downward filtration through land" process of Frankland, and when once the principles underlying that process have been grasped the mechanism of these newer processes is easily understood. Oxygen is the purifying agent and the air furnishes a practically unlimited supply of this gas. If oxygen is brought in contact with organic matter at the ordinary temperature oxidation proceeds only slowly, but at higher temperatures the same process takes place more rapidly. It is then termed combustion, and this is the process which takes place in refuse incinerators. It is obviously impracticable to evaporate sewage and to oxidise the remaining organic matter in a refuse incinerator, and hence in sewage purification we have to aim at oxidising the organic matter by introducing oxygen in the concentrated or active form in which it occurs in various chemicals (such as permanganates) or by having present along with the oxygen some other substance which hurries up the process of oxidation. The former method proves more expensive than the latter, which is the essential feature of land treatment and artificial biological methods. The other substance which hurries up the process of oxidation is a biological one, either bacteria and other micro-organisms or even larger living organisms, but the actual mechanism of the change is not yet thoroughly understood. It would lead us too far from our subject to discuss the various theories which have been formulated to explain the biological oxidation of sewage, but it may serve a useful purpose to cite the analogous process of manufacturing vinegar from wine. Wine (for this purpose a weak solution of alcohol) is allowed to trickle over shavings which have been inoculated with a specific bacterium (*Mycoderma aceti*), and in doing so the alcohol in the wine is oxidised to acetic acid; the wine is converted into vinegar. Vinegar is an oxidation product of wine, just as carbon dioxide and nitrates are oxidation products of the organic matter in sewage. The analogy serves to suggest that the future may teach us to recognise, to cultivate, and to use specific organisms for the better oxidation of the organic matter of sewage.

Apart from all theories we are on safe ground if we say that the presence of organisms enables the oxygen of the air to oxidise the organic matter in sewage very rapidly, and it remains to consider what are the best methods of bringing the three reacting substances—the organic matter of the sewage, the oxygen of the air, and the organisms—into as intimate contact as possible. In land filtration each particle of the soil becomes coated with a gelatinous film derived from the organic matter of the sewage. This film forms a nidus for organisms and at the same time such an extensive surface that it attracts more organic matter out of the sewage and a partially purified liquid passes on to the next particle of soil, where the process is carried a stage further. Following the sewage comes a supply of air, and we thus have the three reacting substances together. Oxidation takes place and the gelatinous film on the soil particle is ready for another dose of sewage. In the case of contact beds and percolating filters the mechanism of the process is somewhat similar, except that the material of the beds and filters is very much larger in size than the soil particles, whilst in the case of the activated sludge process the particles of soil or other filtering material are entirely dispensed with and the gelatinous film or activated sludge is agitated with the sewage and air is either blown in or supplied at the surface of the agitated mixture of sewage and sludge.

From what has been said it will have been gathered that activated sludge is produced from the organic matter of sewage and that it is an oxidation product of this organic matter, but the exact function of the oxygen of the air in the production of activated sludge is as yet undetermined. It may be that it fosters the growth of micro-organisms pre-existing in the sewage or even in the air; or that it kills off another kind of micro-organism; or again it may be that it destroys certain constituents of the organic matter or sludge which are inimical to its use for the purpose of purifying further quantities of sewage; or the action may be a mechanical one in developing an enormous surface area on the sludge, but experiments have shown that the addition of chloroform, toluol, and other substances which kill micro-organisms, to a fully activated sludge impair or destroy its activity. We are therefore justified in assuming that activated sludge owes its activity, in great part at any rate, to the micro-organisms which it contains.

[Dr. Calvert described various methods of applying the activated sludge process to the treatment of sewage, notably those used in this country at Worcester, Manchester, Bury, Birmingham, and Sheffield respectively. He continued:—]

Certain Difficulties.

Before the process is applied to any sewage, or indeed before any kind of sewage treatment works are constructed, it is of prime importance that full information should be obtained as to the volume and nature of the sewage which may be expected to reach the works.

Included in the question of volume of sewage is the question of storm water, but the indications of existing plants are that if the final settling tanks are of sufficient capacity the plants are able to deal with three times the dry weather flow for periods which are generally likely to occur in times of storm. This, of course, presupposes that the first rush of storm water does not wash out of the sewers too much solid matter which has been deposited in the sewers during dry weather and become septic, and also that the flow of storm water is not so prolonged as to give rise to the phenomenon which has been termed "bulking" of the sludge.

This phenomenon, about which little definite information is available, is due to a condition which activated sludge assumes under certain unknown conditions. At times it is found that the sludge, in a comparatively short space of time, say a few hours, swells up and occupies a much larger volume of the tank space than normally. If the normal amount of sludge is, say, 20 per cent. (measured after settlement for one hour) it is sometimes found that the sludge, whilst containing no more dry solid matter, will occupy a volume twice as great or even greater. Under such circumstances it is often difficult to maintain the requisite amount of sludge in the aerating or agitating tank and to prevent it escaping with the effluent from the final settling tanks.

Included in the question of the nature of the sewage we have not only the variations in strength due to varying water consumption and to variations due to the class of the population tributary to the sewers, but also the question of any trade refuse which may be admitted to the sewers. Here our knowledge is not by any means definite, but the indications are that with domestic sewage the application of the process presents little difficulty. With trade refuse, however, the matter is otherwise, and difficulty has been experienced with such classes of refuse as spent gas liquor, brewery waste, oil and tar, and refuse from the manufacture of dyestuffs. The process is able to deal with certain proportions of these classes of refuse in the sewage, but it would appear that when once the sludge has acclimatised itself to those proportions any very material variation either up or down is likely to cause difficulty, either by depriving the sludge of its activity or by giving rise to "bulking."

These difficulties can be counteracted to some extent by the preliminary treatment to which the sewage is subjected before it enters the activated sludge tanks. Such preliminary treatment should always include screening and the removal of grit in detritus tanks.

The final settling tanks, following the aeration, agitation, or activated sludge tanks, serve the purpose of separating the activated sludge from the purified sewage and concentrating the former for return into the process tanks or for disposal of the surplus, for more is always produced than is required in the process tanks. The form of construction which has been almost always adopted for these tanks is that of the Dortmund or hopper-bottomed tank.

The volume of sludge which is returned from these tanks into the process tanks is regulated according to the amount which it is desired to maintain in the process; 15 or 20 per cent. (measured after settlement for one hour) may be regarded as an average amount.

It is difficult to give figures relating to the cost of the process, the power consumption, and the size of plant which may be regarded as the smallest economical unit, since local circumstances vary so enormously. The capital constructional costs of a plant to deal with a daily dry-weather flow of a million gallons of average domestic sewage, and with three times this volume in wet weather, would be under average conditions, approximately £30,000, and the annual working costs from £1200 to £1400. The power required has been found to vary from 15 to 30 h.p. per million gallons, but the price of electrical energy varies at the several plants from ½d. to 4d. per Board of Trade unit. Skilled supervision is necessary where the process is installed, and it is not usual, though it might be advantageous, to provide such supervision at small works where the daily dry-weather flow is less than, say, 500,000 gallons.

A Modified Process.

The methods of application of the activated sludge process aim at what is termed the complete purification of the sewage—that is, the production of an effluent which is non-putrescible and which is not likely to give rise to a nuisance when discharged even into the smallest watercourse. We will now turn our attention for a moment to a modification of the process which has been worked out at Birmingham and which promises a wider applicability.

At Birmingham the basic idea is to stop the purification process at an early stage, separate the partially purified liquid from the partially deactivated sludge, and reactivate the sludge separately for re-use in the process. The partially purified liquid is then passed on to existing percolating filters at a rate of two or three times the ordinary rate of feed. The short period of agitation enables the plant to be constructed correspondingly smaller, but the reactivation or reaeration of the sludge in the concentrated form is a more difficult matter than in the dilute form, so that the size of plant necessary for this part of the process is not reduced strictly in proportion to the concentration of the sludge. A large-scale plant to deal with 2½ million gallons per day has been operated on these lines for some time at Birmingham, and the size of the plant is now being trebled. Local conditions make the process peculiarly applicable. The settlement tanks are situated some four or five miles higher up the valley than the percolating filters, and in traversing the carrier between the two portions of the works the tank liquor becomes septic and is liable to give rise to nuisance from smell when it is sprayed on to the percolating filters. The partial treatment, or bio-flocculation, as it has been termed, for it consists essentially in a flocculation of the colloidal organic matter in the sewage, deprives the sewage of its septic character, so that no nuisance from smell is caused when the sewage is sprayed on to the filters, and owing to the high rate of feed of the filters the normal extension of filter area to meet the needs of increasing population is avoided. It is also probable that with this partially purified liquor the question of fly nuisance on the percolating filters will be lessened.

The process is a peculiarly inviting one, for there are few large towns in a position to afford absolutely new sewage disposal works, and most of the activated sludge plants installed in this country have been adjuncts to existing works which required extension. In most cases they deal with a portion of the whole flow of sewage and not with the whole flow and its daily variations. The process in use at Birmingham affords an opportunity of extending existing works, especially where percolating filters exist, without separating the works into two parts and without constructing further expensive percolating filters.

The Nature of Activated Sludge.

When seen in the aeration tanks activated sludge has a brown flocculent particulate appearance, and the experienced eye can judge its activity, knowing that a greyness and ultimately a blackness comes over it when it loses its activity. Under the microscope great differences are seen in activated sludge produced at different places.

From its mode of formation activated sludge contains the whole of the mineral matter present in the settleable and colloidal solids of the sewage, and such portions of the organic matter as have not been oxidised to gaseous or soluble forms. The particles of sludge are heterogeneous masses which have a tremendous surface per unit of weight, and they teem with life. Many forms of bacteria and other organisms have been recognised in the sludge, but up to the present our knowledge of these forms of life and their functions is very limited. It would appear that the phenomenon of "bulking," to which reference has been made, is associated with the preponderance of protozoal forms.

Activated sludge has a higher percentage nitrogen content than ordinary sewage sludge, and percentages of 5 or 7, measured on the absolutely dried sludge, are not uncommon.

Experiments have demonstrated that activated sludge possesses a higher manurial value than ordinary sewage sludge and that its nitrogen is as available for plant life as the nitrogen of sulphate of ammonia. For horticultural work and the dressing of golf greens and in market gardens the activated sludge produced at Milwaukee and Chicago has been dried and put up in 100 lb. bags and has found a ready sale. The problem of using activated sludge as a fertiliser has not yet been tackled seriously in this country, and at the various works where it is produced it has been dealt with much on the lines in which ordinary sewage sludge has been dealt with—by shallow ploughing into the land, by lagooning, or by drying on special drying beds and then spreading on the land. At most works it is mixed with the ordinary sewage sludge produced at another part of the works, but in no case has a preliminary dewatering in presses or filters with subsequent drying by heat in mechanical driers proved successful. At Milwaukee and other places in America very large plants have been constructed to deal with the sludge on these lines, but whether the success which is reported from these plants is due to some difference in the American sludges or to a want of vision on our part is not clear.

There is still a chasm of ignorance concerning the activated sludge process of sewage treatment. Much more research will have to be done before we are in a position to define the future possibilities of the process, but there is every reason to expect that these possibilities will be large.

OPHTHALMOLOGY IN EGYPT.

MODERN Egyptian ophthalmology, which owes its inception to the late Sir Ernest Cassel, who endowed the ophthalmic hospitals, and to Mr. A. F. MacCallan, who during his twenty years' residence in the country organised their work, continues to flourish. This year's report of the Ophthalmological Society of Egypt records an increase of three permanent and three travelling hospitals during the years 1924 and 1925, the number of new patients treated in the latter year having increased to 236,903. The main cause of blindness, as in all Eastern countries, is trachoma, but it is encouraging to read that whereas in 1919 the percentage of blindness in one or both eyes among the patients was 15·3, this percentage has been gradually reduced until in 1925 it was 10·4. There is an entertaining paper in the current *Bulletin* of the Society by Dr. Max Meyerhoff entitled New Light on the Early Period of Arabic Medical and Ophthalmological Science. It contains photographs of anatomical sketches from an Arabic manuscript of the year 1003 A.D., now preserved in a private library at Cairo. One of the diagrams shows the external ocular muscles, and another the decussation of the optic nerves at the chiasma.

DENTAL CARE OF MOTHERS AND YOUNG CHILDREN.

AT the quarterly meeting of the National Baby Week Council, held at Carnegie House on Nov. 17th, a discussion on Dental Care of Expectant and Nursing Mothers and Children under Five was opened by Dr. Helen P. Dent, of Leicester. She said that anæmia, digestive troubles, and debility followed an unhealthy mouth, and it was quite possible that pyorrhœa might have a share in the production of puerperal sepsis. There was much ignorance and prejudice amongst mothers in regard to the need and the safety of dental treatment during pregnancy. The provision of dental treatment for mothers should always be part of the local authority's maternity and child welfare scheme, and it should be available at least for all those attending the welfare centres, whether they were expectant or nursing at the time or not.—Dr. Harry Campbell said that caries was absolutely preventable, and pyorrhœa largely so; if teeth were kept perfectly clean they would never decay. The food given to young children was often not of a kind to develop mastication; the greater part of the right sort of food belonged to the vegetable kingdom, and a considerable proportion of farinaceous food which compelled grinding should be provided.—Dr. Vincent Denne emphasised the importance of the hereditary factor in connection with teeth. Many women suffered from malnutrition owing to diseased teeth. Toxins from the teeth were absorbed, and the infant was not only badly nourished but poisoned. A number of women were unable to suckle their infants; they could not elaborate the ingredients of breast-milk because they were damaged by bacterial infection. There was no reason why fillings should not be carried out at any time during pregnancy and extractions until quite an advanced stage, if proper precautions were taken.

A CHEQUE for 100 guineas has been sent to the New Health Society by a firm of cigarette manufacturers as an expression of regret for having inadvertently included in an advertisement a photograph of Sir W. Arbuthnot Lane.

A Discussion
ON THE
DIAGNOSIS AND TREATMENT OF COLITIS.

The Opening Paper in a Discussion on Colitis at the Medical Section of the Royal Society of Medicine, on Nov. 23rd, 1926,

BY ARTHUR F. HURST, M.D. OXF.,
F.R.C.P. LOND.,
PHYSICIAN TO GUY'S HOSPITAL.

THE Committee of the Medical Section of the Royal Society of Medicine has acted wisely in choosing colitis as a subject for discussion. No diagnosis is made more frequently and with less justification. In most cases in which colitis is diagnosed, a name indicating a definite organic disease is given to explain the presence of symptoms which are purely functional in origin, and much time and money are spent on vaccines, intestinal douches, and visits to spas, when nothing more than a little judicious psychotherapy is really required. On the other hand, the same diagnosis is often made when a much more serious condition—cancer of the colon or rectum—is really present, and weeks or months are allowed to pass with futile bacteriological or local treatment until all chances of cure by a radical operation are lost. It is clear, therefore, that colitis should never be diagnosed until a thorough investigation has shown that inflammation of the colon—nothing less and nothing more—is present.

There is nothing characteristic about the subjective symptoms of colitis. Pain and tenderness are often absent even in the most severe cases. All that can be said is that when discomfort or pain is present in the lower part of the abdomen the possibility of some disorder of the colon requires consideration.

1. THE STOOLS.

The state of the bowels is of much greater importance, but it is essential that the patient's statements should not be accepted without examining the stools. It is quite insufficient to ask the patient to send a specimen in a small bottle. Each stool passed on two or three consecutive days should be inspected by the clinician, in addition to the microscopical and bacteriological investigations carried out by the pathologist. It is essential, too, that the stools should be natural ones and not obtained after an aperient or an enema.

Mucus.—Many people, medical as well as lay, appear to regard the presence of mucus in the stools as evidence of "mucous colitis." It should be remembered, however, that it is a function of every healthy mucous membrane to secrete mucus under certain conditions. In the colon it is normally secreted in order to protect the mucous membrane from mechanical and chemical irritants. Consequently hard fæces are likely to be coated with mucus, which at the same time facilitates their evacuation; it is secreted chiefly in the pelvic colon, where the fæces normally accumulate before evacuation, and, in patients with dyschezia, in the rectum.

Most aperients act by irritating the mucous membrane of the bowel; it is therefore natural that, unless the dose is very small, the soft or liquid stools to which they give rise should often contain mucus, secreted with the object of diluting the chemical irritant and so protecting the mucous membrane from damage. A similar response frequently occurs after injecting fluid into the bowel; the old custom, still followed in some spas, of sending every patient for a trial Plombières douche and, if mucus is found in the ejected fluid, diagnosing colitis as the cause of the rheumatism, eczema, or neurasthenia, for which the patient seeks treatment, has no scientific foundation, because many healthy colons respond to the abnormal stimulation of the douche by secreting mucus, even if the secretion gradually diminishes during the "cure," as the mucous membrane becomes accustomed to the treatment. Whenever possible, I like to examine a patient with the sigmoidoscope without any preparation by aperients or lavage, as I have frequently observed that the latter cause the mucous membrane to be slightly redder than usual and excess of mucus to be present, even if nothing more irritating than normal saline solution is used for the douche. The temporary congestion and the secretion of mucus under these conditions are the natural response to the irritant and are not signs of colitis. The mucus secreted with hard fæces and after the use of aperients or enemas contains no pus cells, no red corpuscles, and no excess of broken-down epithelial cells; evidence of inflammation is entirely lacking.

In the condition badly described as muco-membranous colitis, shreds or large membranes of mucus are excreted with hard fæces. I have repeatedly sigmoidoscoped patients with this condition, and I have never seen the slightest sign of inflammation, unless they have been treated with irritating douches. Nearly 20 years ago I suggested that this condition was strictly analogous with asthma; I still think that the analogy holds good. In asthma over-activity of the vagus leads to spasm of the bronchial muscles and excessive secretion of mucus by the bronchial mucous membrane. Owing to the spasm the mucus is retained long enough to coagulate, and, as it is slowly extruded along the spiral bronchi, it is moulded into the characteristic Curschmann's spirals. In uncomplicated cases there is no bronchitis, and the mucus contains no pus cells or albumin; the secretion ceases abruptly when the spasm relaxes at the end of an attack, whether this occurs spontaneously or after an injection of adrenalin. In the colon the spasm and over-secretion of mucus, which have been shown experimentally to occur on stimulation of the pelvic nerves, are due to similar nervous influences; the mucus, which contains no albumin and no pus cells, is retained owing to the spasm and is coagulated by a ferment, mucinase, which Roger [1] has isolated from both the bronchial and intestinal mucous membrane. Just as asthma may be complicated by bronchitis as a result of treatment by irritating inhalations, so muco-membranous colic, as it should be called, may be complicated by a mild form of true colitis as a result of daily irritation by injudicious local treatment. It is this fact which led Mathieu many years ago to say that more cases of colitis came from Plombières than went there, and I have no doubt from my own experience that this is also true of many other spas, both at home and abroad, though matters have greatly improved since the war.

Pus and Blood.—In true colitis the mucus always contains pus cells, and in the severe forms small quantities of pure pus can often be recognised in the stools. Microscopical examination reveals the presence of disintegrated epithelial cells, often in large numbers, but the presence of such cells without pus or mucus is not necessarily pathological. The presence of blood recognisable with the naked eye in a stool containing mucus and pus, whether mixed with them or in separate bright or dark red clots, generally indicates the presence of ulceration, but smaller quantities, and especially isolated red corpuscles only recognisable with the microscope, may be present in acute colitis without actual ulceration. When the source of blood and pus in the stools is the inflamed mucous membrane of the colon, the stools are always soft and generally liquid. In the typical stool of ulcerative colitis isolated patches of liquid fæces, mucus, pus, and blood can generally be recognised, in addition to muco-pus and pus stained with blood. The presence of solid fragments of fæces in such a stool would point strongly to the presence of a growth. When blood is passed alone or on the surface of lumps of solid fæces, together perhaps with a little mucus or muco-pus, colitis is certainly not the cause, and a local source in the anal canal or rectum should be looked for.

2. BACTERIOLOGY.

Incredible as it may seem, I have often met with cases in which colitis has been diagnosed simply because an examination of the stools has shown that the relative proportion of streptococci to *B. coli* differs from what the pathologist regarded as normal, or because he has isolated certain organisms which he did not regard as normal inhabitants of the bowel. It is not sufficiently realised how wide are the variations in the fæcal flora of normal individuals, and how greatly the number, character, and proportion of the bacteria present are influenced by diet and by changes in the consistence of the fæces, such as may be caused by the use of an aperient. It is also, apparently, forgotten that pathogenic organisms in the sputum, tonsils, or teeth may find their way into the fæces without causing infection of the mucous membrane of the alimentary tract, and how even typhoid bacilli or other obviously pathogenic organisms may be discovered in perfectly healthy carriers long after they have recovered from the acute infection. Moreover, intestinal toxæmia may result from the absorption of poisons produced by excessive bacterial decomposition of proteins in the intestines in the complete absence of enteritis or colitis.

There can, of course, be no doubt that colitis of all kinds is almost always due to infection of the mucous membrane of the colon. But, unfortunately, our knowledge of the normal intestinal bacteriology is still so incomplete that it is rarely possible to recognise which of the organisms found in the stools of a definite case of colitis is responsible for the development of the disease. In most cases the abnormal flora in ulcerative colitis are not due to the infection, but to the fluid nature of the stools and the presence of excess of soluble protein, blood, and pus, which form a culture medium specially favourable for the growth of certain bacteria at the expense of others. When allowance was made for this, the evidence in favour of any particular organism found in the stools being the cause of the colitis has, in no single case coming under my observation, appeared to be conclusive.

In a report on an epidemic of "idiopathic ulcerative colitis," which resulted in 118 deaths in the Lancaster County Asylum in 1898, Gemmel [2] expressed his belief that this condition, which had always been well known in asylums, was really dysentery. Vedder and Duval,[3] working under Flexner in 1902, proved that epidemics of "dysentery" occurring in institutions in America were caused by the *B. dysenteriæ*, and two years later Eyre[4] showed that asylum dysentery in England was also caused by this organism. As the *B. dysenteriæ* is likely to be enormously outnumbered by the *B. coli* in the stools, the isolation of the former, except at the onset of acute cases, is extremely difficult. So far as I am aware, no bacteriologist has yet succeeded in isolating a dysentery organism from the stools in the sporadic disease as it occurs in England, but Dudgeon[5] has isolated the Flexner bacillus from material obtained from the surface of an ulcer through a sigmoidoscope in two cases. I was so struck in 1921 with the resemblance between the appearance of the colon seen with the sigmoidoscope in bacillary dysentery and in sporadic ulcerative colitis that I revived the suggestion made by Saundby[6] in 1906 and Hawkins[7] in 1909 that the latter might also be due to infection with the *B. dysenteriæ*, but in no case have my bacteriological colleagues been able to isolate the organisms from the stools or from swabs taken directly from the ulcers through the sigmoidoscope, and in no case has the patient's blood agglutinated any of the known strains of *B. dysenteriæ*.

In 1924 Barger,[8] of the Mayo Clinic, isolated a Gram-positive non-mannite-fermenting diplococcus from swabs taken through a proctoscope from the ulcers in 80 per cent. of 68 cases of ulcerative colitis, but in only 1 out of 20 healthy patients. Intravenous injections of the diplococcus produced similar lesions in rabbits and dogs. In a few cases the same organism was isolated from apical dental abscesses and from infected tonsils in patients suffering from the disease.

So far as I know these observations have remained unconfirmed until now. Dr. T. Houston, of Belfast, has, however, recently isolated a similar organism, but he is not yet convinced that Barger is correct in regarding it as the specific infective agent in sporadic ulcerative colitis. A recent paper on ulcerative colitis from the Mayo Clinic by Buie[9] raises a suspicion that the ulcerative colitis, from which Barger isolated his diplococcus, is not the same disease as that occurring in England. He refers to "the most significant phase" in its development being the appearance of miliary abscesses immediately beneath the superficial layer of the mucous membrane; these abscesses are said to rupture and leave miliary ulcers. I should have regarded this as a good description of the development of the ulcers in amœbic dysentery; I have never seen anything of the kind in ulcerative colitis and bacillary dysentery, in both of which the ulcers appear to result from superficial necrosis of the acutely inflamed mucous membrane.

3. THE SIGMOIDOSCOPE.

When, 18 years ago, I was invited to take part in the discussion on ulcerative colitis held in this Section, I declined, as I realised I had no knowledge of the clinical aspects of the disease. On reading the report of the meeting it is clear that Mr. J. P. Lockhart-Mummery, who had recently examined six cases with the sigmoidoscope, was the only speaker who was in a position to add anything to our knowledge of the disease, since it was first described in 1875 by Sir Samuel Wilks[10] and subsequently in 1888 by Sir William Hale-White[11] as a result of their observations in the post-mortem room at Guy's Hospital. Since 1908 I have passed the sigmoidoscope in every case in which disease of the colon has been suspected, and I have constantly urged upon others that its use should be regarded as within the province of the physician, just as much as that of the ophthalmoscope. Unfortunately, however, it is still often considered to be a surgical instrument, with the result that numerous cases of cancer, which could not be recognised without its aid, are diagnosed too late, and a totally wrong conception of colitis is still widely prevalent. Nobody would think of treating a case of tonsillitis without looking at the tonsils; it is even less justifiable to treat a case of colitis without looking at the colon, because the symptoms are far less distinctive, and the possibility of cancer can be excluded in no other way.

The sigmoidoscope can almost invariably be passed if the patient is in the knee-elbow position without any special preparation and without causing any pain. Ulcerative colitis can be recognised at the first glance, but the appearance it presents is indistinguishable from that of bacillary dysentery. On the other hand, amœbic dysentery presents a quite distinctive picture, and I have several times been able to diagnose it, occasionally in individuals who had never been abroad, when examination of the stools had failed to reveal either amœbæ or cysts; in every case the diagnosis was confirmed by complete recovery within a few days as a result of treatment with emetine.

If the mucous membrane of the rectum and pelvic colon is quite healthy, ulcerative colitis can be excluded, as the disease seems always to begin in the most distal segment of the colon and to persist there longer than in any other part. When, therefore, stools containing blood and pus are passed by a patient, in whom the sigmoidoscope has revealed no evidence of ulcerative colitis, a growth of the colon is almost certainly present, and if it is situated within 12 inches of the anus it should be possible to recognise it with the sigmoidoscope, even if it cannot be felt by either rectal or abdominal examination.

4. RADIOLOGICAL EVIDENCE.

Certain radiologists, whose work does not bring them into sufficiently close association with the clinical and pathological aspects of the cases they investigate, frequently diagnose catarrh of a part or the whole

of the colon from the appearances obtained with the X rays after an opaque meal. The evidence upon which they depend is very variable, but as the diagnosis is made independently of any pathological or other confirmation, it is, of course, completely unreliable. I have seen numerous patients, who have been treated for months or years for a colitis which they never had, but which had been diagnosed on radiological evidence alone; many had become confirmed hypochondriacs as a result. When the sigmoidoscope has revealed nothing abnormal and the symptoms point to the presence of some disease of the colon, a barium enema should be given. By this means alone is it possible to recognise diverticulitis, a comparatively common disease, which generally involves the iliac and pelvic colon, and which was formerly almost invariably mistaken for either a growth or colitis; it is, moreover, the only common cause of pericolitis sinistra. An opaque enema also often shows the presence of a growth at a stage when it is still impalpable and causes no delay in the transit of an opaque meal.

An X ray examination after an opaque enema should always be made in long-standing cases of ulcerative colitis which are not responding satisfactorily to treatment, as this may be due to the development of a stricture, the exact position and extent of which can be recognised in no other way. By this means the need for a short-circuiting operation was discovered in two of my cases, although there was nothing in the symptoms to suggest that obstruction was developing. The extent of the ulcerative process in the earlier stages can also be recognised with the X rays after an opaque meal by the disappearance of the normal haustration and the mottled appearance of the shadow, but as the whole colon is almost always involved, the examination rarely provides information which was not already available from the known pathological anatomy of the disease.

CLASSIFICATION.

Long-continued irritation of the colon by hard scybala or by aperients might theoretically produce a definite catarrh of the mucous membrane, but there is nothing about the stools or the sigmoidoscopic appearance which makes it possible to recognise such cases from those in which the mucous membrane is still healthy and simply responding to the irritation by the secretion of mucus. Moreover, symptoms and signs of irritation rapidly disappear when the cause is removed, though excess of mucus may continue to be passed for some time. Other mechanical irritants, such as excess of indigestible vegetable residue, and other chemical irritants, such as excess of mustard, pepper, or curry, may exert a similar action, but here, again, it is very doubtful whether they ever give rise to true catarrhal colitis.

On the other hand, the chemical and bacterial irritants resulting from the consumption of decomposing and infected food may leave behind a condition of chronic inflammation after the acute entero-colitis to which it at first gives rise has disappeared. It is necessary, however, to add that the chronic diarrhœa, which is an occasional sequel of acute food poisoning, is more often due to the achlorhydria caused by the associated acute gastritis than to colitis, as no inflammatory products are found in the stools, the sigmoidoscope shows no sign of inflammation, and the diarrhœa ceases abruptly when hydrochloric acid is administered, even if it has been present for several years.

Apart from the specific forms of colitis caused by infection with the *Amœba histolytica* and *B. dysenteriæ*, and sporadic ulcerative colitis with its clear-cut clinical and pathological picture, I am doubtful whether any other forms of severe colitis exist. Occasionally symptoms of ulcerative colitis are found to be associated with a very red and swollen mucous membrane which is not actually ulcerated; I believe, however, that this generally represents an early stage of the same disease. The acute colitis caused by various mineral poisons and the ulcerative colitis which is a rare terminal event in various toxæmic states, such as uræmia, do not come within the scope of to-night's discussion.

COMPLICATIONS.

The high recovery-rate following improved methods of treatment has resulted in the occasional development of late complications, which were formerly rare or unknown. Thus the autopsy records of the London hospitals for the 25 years ending in 1908 did not contain a single example of stricture following ulcerative colitis. I have, however, now watched this develop in four cases*; in the last two the strictures, which were multiple, were so severe that short-circuiting operations had to be performed before complete recovery could occur.

I have also on three occasions watched the development of polypi as the ulceration healed, and Dr. J. A. Ryle tells me he has had the same experience. In a case of polyposis of the colon now under observation there is a long history pointing to a similar origin, and the polypi are still accompanied by severe colitis. I expect that it will ultimately be found that most cases of polyposis of the colon originate during the healing of ulcerative colitis. As the polypi show a definite tendency to become malignant, an intermediate stage of polypus formation was the probable explanation of the development of a growth of the pelvic colon two years after complete recovery from ulcerative colitis in one of my pre-war patients and of cancer of the rectum following chronic dysentery in two others. In one of my cases innumerable small polypi had developed by the time the ulcers had healed; the stools were normal and the patient felt perfectly well. All the polypi disappeared, leaving no trace behind, as a result of treatment with deep X rays by my colleague, Dr. W. L. Watt.†

In spite of the complications I have described the majority of cases heal completely, healthy mucous membrane developing where at one time confluent ulceration was present. Much scarring is often present, but with a magnifying eye-piece the sigmoidoscope shows that this is situated in the submucous tissue, where widespread white scars may alternate with deep red patches of dilated and sometimes stellate blood-vessels; the mouths of new-formed crypts of Lieberkuhn can be seen to be evenly distributed over the whole surface of the mucous membrane. I had recently an opportunity of observing this condition four years after recovery from an exceptionally severe attack of ulcerative colitis which had lasted for three years.

TREATMENT.

The patient should be kept in bed until the sigmoidoscope has shown that complete recovery has taken place. As this may require many months and sometimes even a year or more, a greatly restricted diet, such as one of milk and milk foods, is likely to lead to anæmia and other undesirable complications, which can be avoided by a generous mixed diet, from which everything leaving any solid residue is removed, all vegetables and fruit, for instance, being passed through a fine sieve. Fresh air and exposure to the sun, and in winter to ultra-violet rays, help to improve the patient's general condition. When much blood has been lost transfusion is of great value, not only in combating the anæmia, but also, apparently, by directly increasing the patient's power of overcoming the infection.

Until recently all attempts at specific treatment had failed, as the infective organism remained unknown. In 1919 in the belief that the disease was really an aberrant form of bacillary dysentery, I tried the effect of intravenous injection of large doses of polyvalent antidysenteric serum. In the first case the result was little short of miraculous. A young

* The first two of these cases were recorded in Guy's Hospital Reports, January, 1925, by Dr. C. Ive and Dr. J. F. Venables respectively.

† This case was recorded by Mr. J. G. Kingsbury in Guy's Hospital Reports for 1926 (lxxvi., 101). The other two cases of polyposis, both of whom are now quite well, were described in Dr. Ive's paper, loc. cit.

man, who was almost moribund after being very ill for over a year, and in whom no improvement had followed an appendicectomy, recovered completely in a fortnight; five days after the first injection the sigmoidoscope showed that the innumerable ulcers seen a few days before had vanished, and nine days later the appearance of the mucous membrane was absolutely normal. In the eight years which have since elapsed he has had no recurrence; in reply to a letter of inquiry a fortnight ago he wrote that he is perfectly fit and well able to carry out his strenuous duties as an engineer on the underground railways. Since 1919 I have used antidysenteric serum in every case, often with excellent results, though occasionally with little or none. I realise that the treatment may really be non-specific and nothing more than a form of protein shock, although in one case it proved very effective after a series of injections of ordinary horse serum had failed to produce improvement. The dose of serum I now use is 40, 60, 80 and 100 c.cm., injected intravenously on successive days, and then 100 c.cm. for a few additional days. The reaction is occasionally somewhat alarming, but it is never really dangerous.

Barger and Logan have vaccinated 93 patients with the diplococcus they have isolated from the surface of the ulcers. All have been treated by other means as well, and as they reported that only 10 were "clinically, radiologically, and proctologically" cured, I do not think that there is yet sufficient evidence to say that the vaccine exerts a definite influence on the course of the disease. In the most recent report of the new vaccine treatment (April, 1926) Buie refers to 17 cases in which "the stools became normal and the weight satisfactory, but ulceration in the rectum and sigmoid persisted, as revealed by sigmoidoscopic examination." He then expresses his belief that "the chronic ulcerative colitis was cured in most of these and the ulceration was of the secondary infective type," which he does not think is influenced by the vaccine. It is, however, just this persistent ulceration which presents the chief difficulty in treatment, and it is far from clear what effect the vaccine is supposed to have if such ulcers persist after a course of inoculation. I agree with Barger and Logan as to the wisdom of removing such infective foci as teeth with apical abscesses and inflamed tonsils, though, like them, I have seen a severe local reaction follow the operation. In such cases, which I believe are rare, a secondary infection of the specific ulceration has probably taken place.

Local treatment of the colon is undoubtedly of use. Instead of albargen, which I formerly employed, but which cannot now be obtained in its original unirritating form, I generally use tannic acid (gr. i.–ii. to 1 oz.); in my experience it has been more satisfactory than other silver preparations, potassium permanganate, or acriflavine. It is most important that the fluid should be introduced through a soft catheter, which should not be passed more than an inch beyond the anus, as otherwise the rectal mucous membrane is likely to be injured. I give half an ounce of charcoal and kaolin two or three times a day in the hope that they will absorb toxins; the former certainly absorbs gas and so relieves colic, and it also deodorises the stools. There is no evidence that any so-called intestinal antiseptic exerts any action in the colon when given by mouth. During the last two years I have tried the effect of a culture of *B. acidophilus* instead of the sour milk I formerly used, but I am not convinced that either is of proved value in overcoming the infection, and in one instance a contaminated preparation led to a severe relapse.

It is of the utmost importance that the stools should not be allowed to get hard during convalescence, and for this reason a saline aperient or paraffin should be regularly taken; the former may also reduce the frequency of defæcation in the early stages and in this way may help to give the patient a less disturbed night. I am convinced, too, that every patient who has ever had ulcerative colitis should for the rest of his life keep his stools soft by means of salts or paraffin, and should avoid all food leaving any solid fragments which could irritate the muco membrane of the colon. The danger of relapse however, largely due to the fact that patients a allowed to get up and discontinue treatment wh they feel well and the stools look normal, which often many weeks before the sigmoidoscope sho that true recovery has taken place.

I have already referred to the occasional necessi for a short-circuiting operation in order to overcor the obstruction caused by the development of stricture in the process of healing. Apart from tl I believe that surgery is very rarely required. T only fatal case I have had among my 19 hospital a private patients since the war was a woman, w died of broncho-pneumonia when she was improvi as a result of an appendicostomy, performed on n advice a few weeks earlier. In three other cases appendicostomy had been performed, but witho obvious benefit; it was allowed to close when th came under my care, and the medical treatment I ha described was substituted with ultimate succes The bowel can certainly be more efficiently wash out through the appendix than from below, and t operation itself is almost devoid of danger, so th in cases which are not improving satisfactorily und medical treatment the question of operation requi consideration; if it is performed, none of the oth forms of treatment which are known to be of u should be discontinued. But the results of medic treatment in my series of cases compares very favou ably with the statistics of appendicostomy. Th in 1923 Lockhart-Mummery [12] referred to 49 cases which 9 died; if to these are added the statistics Logan from the Mayo Clinic (51), Bastedo,[13] of Ne York, and Strauss [14] of Berlin, we get 118 cases wi 29 deaths, or a mortality of 24·6 per cent., compar with a mortality of 1 out of 19 cases in my serie only 4 of which had undergone appendicectomy.‡

‡ In one case it was found necessary to perform a coloston and excise the pelvic colon and rectum owing to persistent rect hæmorrhage; this was, however, done at the patient's hom several months after she had left hospital against my advice, I believed that further treatment would have resulted in a cur a belief which was, I think, confirmed by the pathologic examination of the exeised bowel, which showed that healin had progressed so far that nothing more than a few superfici erosions of the mucous membrane were still present.

ROYAL MEDICAL BENEVOLENT FUND.—The followin are some additional cases relieved at the last meeting:—

M.R.C.S. Eng., aged 63. After an assistantship ended 1924, tried to establish a practice in the Midlands, but has h to give it up on account of deafness. From the practice mad £47. Gifts from relatives £6. Board and lodging £68. Fun voted in 1925 £30, and this month £40 in 12 monthly instalment

Daughters, aged 62 and 54, of M.R.C.S. Eng. who died in 190 Eldest suffers from phlebitis and younger one is epilepti Total income amounts to £79 per annum. Rent and rates £3 Relieved 18 times, £393. Voted £26 in 12 monthly instalment

Daughters, aged 64 and 66, of M.R.C.S. Eng. who practise in Wales and died in 1873. They live in a two-roomed hut f which they pay £1 per annum for ground rent. One has th R.U.K.A. Annuity of £26, and they made £5 from poultry Friends gave £7. Relieved 10 times, jointly £154. Last yea voted £24 each in monthly instalments, which was renewed.

SOMNIFEN TREATMENT IN THE PSYCHOSES.

BY W. S. DAWSON, M.D. OXF.,
SENIOR ASSISTANT MEDICAL OFFICER;
AND
M. R. BARKAS, M.D. LOND.,
ASSISTANT MEDICAL OFFICER, MAUDSLEY HOSPITAL.

THE use of "Somnifen" for the production of a state of twilight sleep in psychotic cases has had a considerable trial abroad since the first publication by Kläsi in 1922.[1] The general opinion held after three years was summed up by Müller[2] in 1925—namely, that while the induction of such a twilight sleep lasting about a week has proved of sufficient value to be accepted as a useful form of treatment, the use of somnifen for its production has dangers and disadvantages—the death-rate among cases recorded being about 5 per cent.—that this drug should be used only as one of the many available hypnotics, and that suitable combinations of these should be tried according to the requirements of the individual case.

In England the new drug was first tried at the Maudsley Hospital in September, 1924. The advantages claimed for it over the other drugs of the barbituric acid group are that it is soluble and, therefore, readily absorbed and excreted, and its solution is stable, so that it can be kept and used conveniently for intramuscular and intravenous administration. In the annual report of the medical superintendent of the hospital for 1925 mention is made of the effects produced. In view of the recent notice in THE LANCET (Sept. 25th, p. 662) of the results achieved abroad, it seems worth while to report a series of cases in which it has been used in this country.

Kläsi emphasises that it should be used strictly according to his method—namely, giving at first an injection of morphine gr. ¼ and hyoscine gr. 1/100, followed in half an hour by two ampoules each containing 2 c.cm. of somnifen solution (diethylamine diethyl dipropenyl barbituric acid). The injection must be injected deeply into the muscles if not given intravenously, as subcutaneous injection produces sloughing. After this a twilight sleep condition must be maintained by doses of one ampoule at intervals, usually of six to eight hours. The treatment is best carried out in a darkened quiet room; fluid diet, attention to excretion, and careful watching of the pulse are needed, and the patient can be roused for attention and will doze off again. If he is allowed to become fully awake the treatment must be restarted. Contraindications are heart or kidney disease or extreme emaciation. The treatment must be stopped if vomiting or cardiac failure occur, and during menstruation.

The cases treated may be divided into (1) those given the full course according to Kläsi's plan, being kept in a twilight sleep state for five days or more; (2) those started in this way and stopped for some reason; (3) those given in a different way.

1. The first group contains seven female and six male cases.

Females.—1. Mrs. A., aged 30; post-puerperal confusion with hallucinations, five months duration. Morphine and hyoscine (M. and H.) followed by two ampoules somnifen, and ten subsequent doses of one ampoule in five days, with two doses of paraldehyde in addition; only occasionally restless and slept most of the time; stopped as she became more restless and vomited. Rather quieter and more accessible for about one month, though still hallucinated; relapsed then, and no further improvement.

2. Miss B., aged 28; acute melancholia with delusions of unworthiness; agitated but not hallucinated. Had strict somnifen treatment (M. and H. followed by two ampoules) and then ten ampoules in five days; slept constantly, cyanosed hands became warm and moist, pulse became rapid and weak, so that treatment was stopped. Improved considerably for about a week, during which she was interested in occupations and mildly depressed, but relapsed badly after that, and became hallucinated for sight and hearing and acutely suicidal.

3. Miss C., aged 32. Case of ten years recurrent attacks of excitement and depression with hallucinations; was confused, incoherent, hallucinated, and restless. M. and H. followed by somnifen, two ampoules, and then 11 doses in five days; constant drowsiness; stopped because pulse became weak. Marked improvement for about a week, accessible, clear, no hallucinations, then relapsed into alternating between days of normality and days of hallucination and incoherent chatter.

4. Miss D., aged 19; acute mania; noisy and destructive. M. and H. followed by somnifen; kept drowsy and quiet for seven days with 22 doses of one ampoule; had retention of urine and cystitis. Required other sedatives for a time, then lapsed into confused depressed state and finally recovered some months later. No evident benefit from somnifen over other sedatives.

5. Miss E., aged 28; acute mania; three months noisy, destructive, and dirty; M. and H. followed by somnifen, then one ampoule b.d. with a few doses of paraldehyde; remained drowsy and quiet; total nine doses in five days; quiet and rational for two days after, then relapsed completely. Stopped because pulse became weak.

6. Mrs. F., aged 31; recent melancholia, screaming in agitation. Given digitalin (nativelle) 1/600 with each dose, as pulse poor from start; had one ampoule eight-hourly for five days, needed 1 drachm of paraldehyde in between, with this remained quiet and drowsy; treatment stopped as pulse weaker. No subsequent improvement.

7. Mrs. G., aged 27; puerperal mania. Received six ampoules of somnifen in four days in addition to three injections of ¼ gr. morphine and 1/100 gr. hyoscine. The excitement was reduced, but the periods of drowsiness were very brief. The course of the excitement was not influenced.

Males.—8. Mr. H., aged 47. Acute depression with agitation and phases of vivid hallucinosis. Treatment was begun with M. and H., followed by nine ampoules of somnifen given over a period of five and a half days. The patient remained drowsy while the drug was given, but afterwards relapsed to his former state. The treatment was repeated two months later and ten ampoules were given over a period of six days, but there was no physical or mental improvement beyond a gain of a pound in weight.

9. Mr. I., aged 43. Manic phase of manic depressive psychosis. After M. and H. he received seven ampoules in seven days, together with several doses of paraldehyde. The excitement was controlled and drowsiness maintained, but there was no lasting benefit.

10. Mr. J., aged 41. Mania. Received seven ampoules in six days as well as bromides, and was quiet and drowsy during this period, but relapsed afterwards.

11. Mr. K., aged 60. Tabes with agitated depression. Received six ampoules in five days when the treatment was discontinued owing to signs of cardiovascular failure.

12. Mr. L., aged 55. Agitated depression with arteriosclerosis. Received five injections in four days, together with several doses of paraldehyde. He became collapsed, but the signs of cardiovascular failure passed off when the drug was discontinued. The course of the depression was not influenced.

13. Mr. M., aged 23. Acute excitement, probably schizophrenic. Emotionally exalted with hallucinations and rather fantastic delusions. He received six ampoules in five days and seemed to be better for some days afterwards, but then relapsed to his former state.

2. In four cases treatment by somnifen was stopped prematurely.

1. Mrs. O., aged 35. Anxiety state passed into agitated depression with hallucinations; restless, impulsive, confused. M. and H. and somnifen started, six doses given in three days; no twilight sleep could be maintained and pulse got very weak and rapid, so that treatment was stopped.

2. Miss P., aged 50. Agitated melancholia with fears of torture, &c. Given M. and H. and 2 ampoules somnifen, slept well all night but awoke next day with persecutory delusions about the injection and very agitated and resistive; treatment was not continued as she had been getting more agitated for some time and no benefit appeared from the somnifen sleep.

3. Mrs. Q., aged 28. Acute confusion with hallucinations; agitation and restlessness following childbirth—possibly encephalitis lethargica. Somnifen one ampoule was given, but her pulse became bad and no further doses were given.

4. Mrs. R., aged 27. Acute mania of some months duration. Given one ampoule somnifen twice and slept well on it, but her pulse became weak and colour bad, so it was discontinued.

3. One other case—a long-standing hypochondriacal woman of 27 with vague ideas of suspicion and intractable sleeplessness which resisted all drugs, was given M. and H. followed by somnifen every night for four nights; on two she slept well, another night she needed paraldehyde in addition, and then she

was kept awake by a sore arm from some necrosis around the site of injection of somnifen, so that treatment was stopped. Here there seemed only slightly better sedative effect than with other drugs, and her sleeplessness and general mental condition was unaffected.

Conclusion.

Summarising these results, one may say that in most cases where the treatment can be continued a twilight sleep state can be maintained; that any improvement following this treatment is quite transitory, there being no change at all in some cases; that there are considerable risks attached to the use of somnifen, as in many instances the pulse becomes progressively weak, rapid, and often irregular: and that while in our series there have been no deaths—this is largely owing to careful watching of the heart's action and stopping treatment in good time. Only one case had retention of urine and cystitis. The improved contact with the environment claimed by Kläsi was not conspicuous, a few cases showing it for a few days only and then relapsing. Generally speaking, one may say that somnifen, as a soluble sedative which can be given intramuscularly, has its place in the list of available sedatives for psychotic patients, but has considerable risks and no special advantages. If a twilight sleep of some days duration is of benefit in some cases, this has not been evident in our series, and the advice of Müller may well be taken, to produce it where desirable by means of combinations of hypnotics rather than by somnifen.

We wish to thank the medical superintendent of the Maudsley Hospital, Dr. Edward Mapother, for his permission to publish these cases.

A CASE OF LYMPHATIC LEUKÆMIA OF UNUSUAL TYPE.

BY A. E. NAISH, M.B., F.R.C.P. LOND.,
LECTURER ON MEDICINE, SHEFFIELD UNIVERSITY, AND PHYSICIAN TO THE SHEFFIELD ROYAL HOSPITAL;
AND
CLARA TINGLE, M.D. SHEFF.,
PATHOLOGIST, SHEFFIELD ROYAL HOSPITAL.

WE have provisionally classed this case as lymphoid leukæmia. It presents certain remarkable features, and is recorded in view of the interest that is now being taken in the pathology of blood diseases and the difficulty of classification of border-line cases.

Male, aged 16, admitted to Sheffield Royal Hospital on March 11th, 1925, and died on Sept. 30th, 1925.

He was working as a hammer driver in October, 1924, when he wounded the middle finger of his right hand. It became septic later and was "lanced." Three weeks afterwards a lump appeared above the right elbow and another in the right armpit. They were at first painful, but the tenderness gradually disappeared, though the lumps remained up to death. In the latter half of November lumps were noticed behind both ears, and a little later in other parts of the neck and under the chin. In December the eyes became bloodshot and shortly after this he had to cease work on account of weakness. About February his face became puffy and discoloured and dark patches began to appear on the skin wherever it was rubbed. At this time also some lumps were noticed over the shoulders. The appetite was becoming more and more impaired, he vomited sometimes, and he had particular difficulty in swallowing hard solids. The bowels were opened regularly, and occasionally the stools were noticed to be very black.

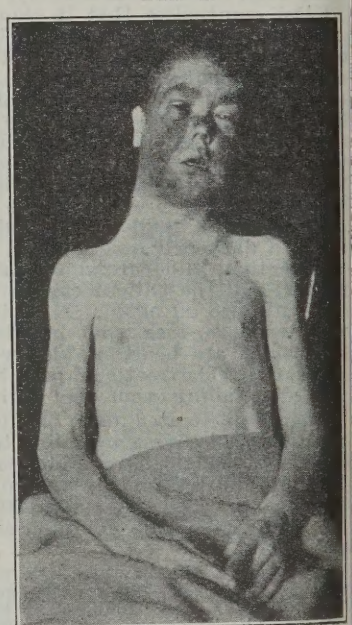
Previous History.—Scarlet fever at 5, followed by glandular swelling in the neck and operation. Influenza at 8; in bed two months. Has always bled freely when cut.

Condition on Admission.—The whole face was puffy and swollen; very marked purplish discoloration of the cheeks, eyebrows, and chin. Eyelids swollen so as to produce a condition of half closure; large subconjunctival hæmorrhages on both sides. The skin of upper part of chest shows numerous purple lines, suggesting subcutaneous hæmorrhage caused through scratching himself. Deep purple discoloration around both nipples. Ears: Old-standing otitis media suppuration with loss of both tympanic membranes. Larynx: General infiltration, swelling, superficial ulceration, and ecchymosis of the epiglottis. Hard and soft palate, including the alveolar portion, swollen and infiltrated with areas of ecchymosis. Lymphatic glands: In the neck there was widespread moderate enlargement of glands in both anterior and posterior triangles; there was a chain of rather smaller glands running the anterior border of each trapezius muscle. Numerous glands in both axillæ and groins showed enlargement. The right supratrochlear considerably enlarged and somewhat tender, left only slightly enlarged. Some comparative dullness for two inches to the right of sternum in first and second interspaces. No glandular enlargement detected in the abdomen. Besides the enlarged glands there were some other subcutaneous lumps, evidently not in the position of normal lymph glands. The largest are four about the size of a bean, one above and one to the outer side of each scapula. Heart: No apparent enlargement. A faint systolic bruit heard along left border of sternum. Lungs and pleuræ: At left base there was a small area of comparative dullness with diminished breath sounds and voice sounds. Abdomen: Liver somewhat enlarged; margin reached about one finger's-breadth below ninth costal cartilage. Spleen just palpable; its area of dullness considerably enlarged. No evidence of ascites detected.

Ophthalmoscopic examination: Both retinæ appear to be a brighter red than normal; edges of both discs blurred, especially that of left eye. No hæmorrhages detected. Wassermann reaction and blood culture give negative results.

Blood count: Red blood cells, 4,260,000; hæmoglobin, 78 per cent.; colour-index, 0·91; white cells, 10,10[illegible]. Differential count (per cent.): polymorph. neutrophils, 4; polymorph. eosinophils, 1·5; small mononuclears, 40; large, 49; cells transitional between the two last, 5·5. The small mononuclear cells were comparable in size to the small lymphocytes found in normal blood. The cytoplasm was, if anything, a little more in proportion to the nucleus, but in other respects such as appearance and staining properties they were indistinguishable from a normal small lymphocyte. The large mononuclear cells, on the other hand, showed certain differences from the usual large lymphocyte. In the first place they were sharply marked off in size, being of at least twice the circumference of the small mononuclears. (Cells of intermediate size were always counted separately and were found to be comparatively few; in most counts being not more than 1 per cent. of the whole, and never reaching above 5·5 per cent.) The nucleus of these large cells, although staining rather less deeply than that of the small cells, was not comparable in pallor to that of the large cells described by Sternberg as characteristic of leukosarcoma; neither was it vacuolated or honeycombed as in his description and no mitotic figures were seen. The cytoplasm was abundant, clear, and free from granules; it surrounded the nucleus on all sides, the radius of the cytoplasm being about equal to half that of the nucleus, which is placed nearly centrally. None of the mononuclear cells gave a positive oxidase reaction. The erythrocytes appeared normal in size, shape, and staining properties. No nucleated red cells seen.

FIG. 1.



Progress of the Case.—For the first week after admission the temperature was not raised, but subsequently it was always raised for some part of every successive week; at first only slightly and at irregular periods, but gradually tending to become higher without showing any definite type.

Throughout the whole period of his stay in hospital he seemed weak, drowsy, and disinclined to talk or move about. He would remain all day in bed without speaking a single word if left to himself, but he showed no lack of intelligence when questioned. All the time he was becoming progressively more weak and drowsy, though there were slight remissions. The discoloration of the face remained about the same for a month and then got much deeper, so that about the middle of the summer his face was nearly black. It then became gradually lighter and towards the end it was much less discoloured even than on admission. The general swelling of the face also diminished, but to a less extent, towards the end. The photograph (Fig. 1) was taken not long after admission and, therefore, does not show the intense discolouration which was reached about the middle of his stay. The tendency to ecchymosis on scratching the chest disappeared shortly after admission and never recurred. On the other hand, a mottled purple discoloration appeared on both shins on the rare occasions when he had his legs hanging down, and now and then the same rash appeared on his arms. The glands, after remaining about the same size for a couple of months, slowly began to get smaller, and at the time of his death there was not a quarter of the amount of glandular swelling that there had been on admission. The skin after a couple of months became tender to pressure and scratching the sole of the foot was particularly complained of. Tapping over the bones also produced much pain. By May hæmorrhages had appeared in both retinæ, and from that time onwards they were always detected when looked for. On April 23rd a gland was excised for the purpose of examination. It appeared to the naked eye of a mottled purple colour on section. Microscopically it was found that the ordinary lymph nodes had disappeared and the whole structure was infiltrated by cells which resembled large lymphocytes. These cells were not confined to the gland, but tended to infiltrate the surrounding tissues, including some muscle that was adherent. The liver and spleen became considerably bigger towards the middle of the summer, each reaching down to about the level of the umbilicus. They appeared to shrink a little in size during the last few weeks of life. Signs of considerable pleural and peritoneal effusion appeared towards the end.

Numerous blood counts were made. By April 20th the total number of leucocytes had sunk to 8600, and from this date up to the first week of September the total and differential count remained remarkably constant (the extreme figures being 8600 and 8000) with the lymphocytes almost precisely at 95 per cent. and the relative proportions of small and large not varying greatly from that of the first count. The erythrocytes fell gradually during the first two months to between two and three million and then remained at this level till September. The hæmoglobin followed the red cell count pretty closely. Nucleated red cells were never seen till September, and there was no alteration in size, shape, or staining properties. From the first week of September there was a rapid fall in both erythrocytes and leucocytes. The count on Sept. 25th was: R.B.C., 850,000; W.B.C., 2900; polymorphs, 25 per cent.; small monos., 13 per cent.; large monos., 62 per cent. The fall in the total number of leucocytes had thus taken place mainly at the expense of the small lymphocytes. Normoblasts were now present.

Post-mortem examination Oct. 2nd, 1925.

External Appearances.—Some wasting. Several small soft glands palpable in both posterior triangles of neck and in right groin. Also some deposits felt below the skin in several places—e.g., left forearm and back of neck; these are small white raised nodules, hard to the touch and not ulcerated. No apparent increase in lymphoid tissue at root of tongue.

Chest.—In the anterior mediastinum and along course of great vessels of neck there are many enlarged glands. None are very large, the maximum being $1\frac{1}{4} \times \frac{3}{4} \times \frac{3}{4}$ in. They are very soft, fairly discrete, and deep red on section. In a few of the glands are small white masses about $\frac{1}{8}$ in. across; these are very hard but not gritty, and readily separated from the surrounding gland tissue. It appeared as if the glandular mass was considerably smaller than it had been and was now replaced by œdematous fibrous tissue. Within the glands this change suggestive of shrinkage could be made out; there seemed to be a replacement of the soft hæmorrhagic tissue by dense white connective tissue, affecting first the periphery and spreading centripetally.

Pleura: Small hæmorrhages below the visceral pleura. Lungs: Œdema at both bases. Early broncho-pneumonia with patchy consolidation at the right base. Heart: Marked fatty degeneration of the muscle (tabby cat striation). Pericardium: Sero-fibrinous pericarditis with much blood-stained fluid. Abdomen: Peritoneal cavity contained about two pints of blood-stained fluid. Liver: Weight 70 oz., marked fatty degeneration. A few scattered nodules, dense white in colour, hard to the touch, and about $\frac{1}{8}$ in. in diameter; those on the surface being raised above the surrounding tissue. These nodules were sparsely scattered at intervals of four or more inches. Spleen: Weight 28 oz., deep red and soft. Contains scattered nodules similar to those seen in the liver. Capsule much thickened in parts. Kidneys: Together weigh 12 oz., very pale, especially the pyramids, which on this account stand out conspicuously from the cortex. Capsule strips readily and is not thickened. There are some hæmorrhages beneath the epithelium of the pelvis. Suprarenals: Some general œdema involving also the surrounding tissues. Glands: Many enlarged in the mesentery, along the lesser curvature of the stomach, and in the lumbar region. Bone marrow: Right femur four inches from tip of external condyle. Intensely red in colour. No apparent enlargement of medullary cavity.

Microscopical Examination.

Liver: Sections show aggregations of round cells in connective tissue surrounding portal spaces. These cells are large and mononuclear, and in every way resemble the large mononuclear cells of the blood, except that mitotic figures seem fairly common. A few of these cells are also seen in the sinusoids between columns of liver cells. The aggregations around the portal spaces in some places attain to such a size as to be visible to the naked eye, and in these larger masses there is a tendency to central necrosis. Repeated examinations for bacteria have given negative results. The liver cells show some fatty degeneration (Fig. 2).

FIG. 2.

Section of liver: showing invasion with large mononuclear cells which, in the lower right-hand corner, have become necrotic.

Spleen: The pulp shows evidence of congestion and there is well-marked perisplenitis of a chronic type. Malpighian corpuscles cannot be differentiated. Here and there are seen aggregations of large mononuclear cells comparable to those found in the liver and showing the same tendency to central necrosis where the mass is above a certain size. An occasional large mononuclear is seen in the sinusoids. No organisms found. Lymph glands: Replacement of the glandular tissue by aggregations of the same type of large mononuclear cell, but showing less tendency to central necrosis than in liver and spleen.

Discussion.

The most striking features of this case are: (1) The complete absence of any even temporary leucocytosis. (2) The very low total number of polymorphs. (3) The stability of the leucocyte count over a long period. (4) The character of the large mononuclear cells. (5) The fact that the glandular enlargement began in the right arm shortly after a septic wound of this extremity. (6) The subcutaneous deposits of mononuclear cells and the invasion of muscular tissue in the neighbourhood of glands. (7) The tendency to subcutaneous and submucous hæmorrhage and œdema.

In some respects this case corresponds to those described by Sternberg as leucosarcoma, but (*a*) in his cases the total leucocyte count was particularly high (up to 800,000); (*b*) the type of large mononuclear which he describes has a pale, vacuolated, and honeycombed nucleus with comparatively little cytoplasm, and mitosis is common in the blood; and (*c*) he particularly mentions that subcutaneous hæmorrhage or affection of the skin is very uncommon.

There seems to be here a possible connecting link between germ invasion, leukæmia, and neoplasm, which, in view of Gye's recent work, is not without significance.

THE RATIONALE AND TECHNIQUE OF COMBINING OPERATION WITH RADIUM TREATMENT IN CANCER.

BY WALTER C. STEVENSON, M.D., B.CH., D.P.H. DUB.,

SURGEON TO DR. STEEVENS' HOSPITAL AND THE ORTHOPÆDIC HOSPITAL, DUBLIN.

IT is well recognised that radiation of a cancer increases the difficulties and risks of subsequent operation when undertaken some weeks later to remove the malignant growth. For instance, unexpected deaths have occurred after the removal of a cancerous cervix which has previously been radiated. The difficulty of operation is greatly increased by the amount of fibrous tissue encountered and by hæmorrhage which is not easy to control. These conditions are Nature's efforts to effect a cure, and surgical interference with them appear to be resented by the organism. Furthermore, efficient radiation induces a severe and prolonged state of shock and malaise in all patients, and especially in those whose vitality has already been lowered by disease, partly due to the absorption of products of cell destruction. When the shock of a severe operation is superadded the strain may prove too great for the patient's recuperative powers, and if death does not supervene at once the patient lingers on, fighting a losing battle against metastases, sepsis, and the effect of radiation, possibly lighted up by surgical interference, till the end comes.

Surgeons have from time to time advocated removal of fungating cancerous masses, as a palliative measure, when radical operation is out of the question on account of the extent of the disease. This procedure is justified when it adds to the comfort of the patient, but is an acknowledgment, if not of defeat, at least of abandoned hope of cure. A number of these patients are now treated with radium or X ray alone with fairly satisfactory results. Healing in these circumstances is necessarily very tedious, and much disabling scar tissue is formed in the process, because the patient has not only to cope with masses of malignant cells destroyed by radiation, but also to overcome the chronic septic condition.

The golden rule for successful treatment should be to put as little strain on the patient's recuperative power as possible, consistent with restoration to health. As far as the individual is concerned, not till a growth, or part of a growth, is removed is it finished with. This ablation is all to the patient's advantage and justifies a radical Halstead's operation for cancer of the breast, even though it be followed by great shock. Subsequent radiation as a prophylactic measure is also justified, though it, too, causes shock. The problem is different in inoperable cancer—i.e., one which cannot be removed completely and cured by operation alone, more particularly where it is only possible to get rid of part of the growth by cutting through malignant tissue, the remains of which are left in situ and can spread the disease. The following was such a case.

The patient, a woman aged 41, was admitted to Dr. Steevens' Hospital from the country with a fungating mass the size of a fist, situated in the right breast in a line with the anterior axillary fold. The tumour, an encephaloid carcinoma, bled when touched, was firmly adherent to the chest wall, and broken down in the centre, to a septic foul-smelling crater. There were some glands below and in the axilla; but none could be felt above the clavicle. The patient first noticed the lump in December, 1924. It broke down in June, 1925. The case was inoperable, in the sense that it would have been necessary to remove part of the chest wall in order to avoid disseminating the disease by cutting through malignant tissue and leaving a cancerous and septic area behind.

I was guided in my treatment of this patient by my experience in combined radium and operative treatment of what might be called redundant malignant tissue. Administering to a cancer an efficient radium treatment and operating some weeks later do not appeal to me for the reasons already cited. Radiation by inserting needles or tubes in the parts of dissemination immediately after radical operation is a rational procedure, but increases shock, though probably not to such an extent as when there is much malignant tissue to be acted on. But if a patient is radiated immediately after a partial removal of a growth by operation some of the malignant cells disturbed may escape into the circulation before they are efficiently treated. Also, one is certain to meet with a great deal of hæmorrhage which is not easy to stop, and this naturally increases the shock. I have treated, mainly with beta rays of radium, a number of very vascular fungating malignant growths, mostly on the skin, some projecting from mucous membranes as in the rectum, and in two or three days, or as soon as the treatment is finished, curetted away the redundant tissue till I reached the more or less healthy base. The procedure is surprisingly bloodless, as I give a greatly excessive dose to the malignant tissues which I intend to remove, so that the mass has become practically necrotic and inert when it is surgically dealt with. The redundant tissue, which is useful as a pin-cushion to hold radium needles, acts as a filter to cut off the beta rays from the base of the growth, so that the parts that remain after operation receive gamma ray treatment alone of such intensity as will destroy the malignant cells, but at the same time will not destroy the normal cells and connective tissue, which I depend upon to effect repair in the raw area that is left.

The advantage of this method of treatment over diathermy in the removal of such growths is that the latter produces a necrosis of everything for a certain depth, but beyond that depth has little influence on malignant cells. If the tumour described above were treated in this way necrosis of the ribs might follow, which would be a very undesirable after-effect. As this radium treatment is a local one, and as the greater part of the mass which is treated is removed immediately afterwards, its radiation cannot seriously effect the amount of shock from which the patient may subsequently suffer. As a matter of fact very little shock results from this procedure. When, however, the condition to be treated is such that it requires more than simple removal of a malignant mass, it is necessary to take into account other tissues which have to be disturbed in order to obtain the results required. In the above breast case I wished to deal efficiently with the base of the mass I was about to excise, and also to cover up the raw area left by a plastic operation. I was careful, therefore, not to radiate excessively before the operation the skin I intended to use for this purpose, nor did I think it advisable to treat areas which were suspicious and the paths of the dissemination of the disease before I performed the operation. In fact, I did not wish to run any risks from the constitutional disturbance which would be produced before operation by a prolonged treatment by radium of the glands in the axilla, or in any extension there might be above and below the clavicle, so as to minimise the amount of shock that would be present during any one period of the treatment, especially that following operation.

The actual procedure in this breast cancer was as follows.

At 1 P.M., on Oct. 24th, 1925, without an anæsthetic, I inserted 16 tubes, containing 91·4 mc. of radon divided evenly among them, into the cavity of the growth, and pushed them into the surrounding fungating mass. This caused a certain amount of hæmorrhage, but otherwise did not inconvenience the patient; a 2 mm. thickness of gauze had first been placed at the bottom of the cavity against the chest wall to prevent over exposure in the area which required a lethal cancer dose, but not an overdose. The overdose in the remaining part was immaterial, as I intended to remove it. At the same time two brass boxes containing radon capillaries were applied to the surface over the glands below the axilla as I intended to remove these glands with the superimposed skin. On Oct. 26th, 46 hours later, the fungating mass, still containing the radium tubes, the glands that had been radiated with the skin over them, and some glands further up the axilla and half the breast, including and beyond all the indurated portion were removed

without encroaching on any septic skin. The whole of the breast was not removed, as I expected that the skin brought together over the originally diseased area might not unite owing to the septic condition of the part, and the intensity of the radiation it had received, and I intended to use the remaining skin of the breast to cover this area at a later date. The 16 tubes, after being cleansed and sterilised and arranged in bandolier fashion, were pushed up into the axilla, being separated from the axillary vessels by 1 cm. of gauze and from the anterior axillary fold by three or four thicknesses of gauze, and left there for 24 hours. The skin incision was closed over the breast area, but a small gap remained just at the axilla where two or three stitches were not tied till the tubes had been removed from the axilla. I considered it important to treat the axilla, which had not been previously radiated, immediately it had been incised, so as to minimise the risk of dissemination from this area.

Although the patient stood the operation extremely well and did not appear to suffer from much shock I considered it wiser not to continue the radium treatment at once. On Nov. 6th the chest below the clavicle comprising an area of 14 by 2 cm. was treated by surface application for 42 hours, and the applicator was applied above the clavicle for 60 hours. On Nov. 23rd the area at the top of the incision where the skin had not been quite brought together was treated for 34 hours; a similar dose was given along and in front of the healed incision, and including the part of the breast that was not removed for 37 hours. Three days later the side of the chest behind the incision was radiated. The total amount of energy from radium used up in this case was:—

	Mcd.
Before Operation.	
16 tubes, 3 cm. long, 5 mm. external diameter, wall 1·75 mm. brass. Inserted into fungating mass. Area 6 by 5 cm.	26·7
Surface treatment glands, area 7 by 2 cm., distance 3 mm. brass screen	5·3
Treatment 46 hours, Oct. 24th to 26th, 1925.	
At Operation.	
16 tubes as above, area 8 by 2 cm., inserted into operation wound axilla	10·5
Treatment 24 hours, Oct. 26th to 27th, 1925.	
After Operation.	
Surface treatment at 18 mm. screen and distance piece of felt +2 mm. brass—	
Below clavicle area 14 by 2 cm., 42 hours, Nov. 6th to 8th, 1925	28·1
Above clavicle area 14 by 2 cm., 60 hours, Nov. 8th to 11th, 1925	26·9
Over upper part of incision, area 9 by 9 cm., 34 hours, Nov. 23rd to 25th, 1925	22·6
Over lower part of incision and breast in front of it, area 9 by 9 cm., 37 hours, Nov. 24th to 26th, 1925	22·5
Anterior axillary fold, area 10 by 2 cm., 28 hours, Dec. 9th to 10th, 1925	18·7
Surface beta ray treatment, area 2 by 3 cm. Thin rubber glove filter, distance 3 mm., over unhealed area to stimulate formation of epithelium, 36 hours, Nov. 16th to 17th, 1925	0·3
Total	182·9
Equivalent to 24,400 millicurie-hours or milligramme-hours.	

The above dose is calculated and measured by the destruction or loss of radium emanation (mcd.) during treatment. Radium emanation obtained from the Royal Dublin Society Radium Institute in glass radon capillaries and 53·93 mg. of radium element in six capillary metal cells have been used together indiscriminately. The loss of activity of radon is obtained from a table.[1] The loss from the element is taken as ¾ per cent. in mc. of the mg. of element present. 3 mcd. is equal to 400 mg., or mc. hours.

The patient was in Dr. Steevens' Hospital from Oct. 17th to Dec. 15th (62 days). When she left there was no sign of inflammation or thickening, and most of the operation scar had healed by first intention. A small area below the axilla and above the original site of the fungating mass, which had not been covered with skin at the operation still required dressing. She wrote twice since, on the last occasion at the end of February, stating she was quite well and able to do her house work. One of the most satisfactory results of the treatment is that the whole skin incision, which could be brought together at the operation, healed up at once without the least signs of recurrence or sepsis, in spite of the original septic condition of the breast, the malignant nature of the tumour, and the fact that the operation was incomplete, for the specimen revealed a gap at the bottom of the crater where the cancer had involved the chest wall. I advised this patient to return for a further prophylactic treatment in about two months, but she has not done so.

[1] Walter C. Stevenson: A Convenient Radium Emanation Table for Clinical Work, Archives of Radiology and Electrotherapy, March, 1916; Medical Press and Circular, April 19th, 1916.

It will be noticed that the radium treatment of the above patient was extended over a considerable period to avoid unduly taxing her strength at any one time. The operative interference was also limited to the removal of palpable growth or metastases. The procedure was dictated by the experience of a similar case a year before.

The patient on that occasion was 62 years old, had a growth for six years in the upper part of her right breast, with glands in the axilla and above the clavicle, and chest trouble. The growth had ulcerated through the skin in two places, where there was sepsis and an offensive odour, but there was no fungating mass. On April 29th, 1924, I inserted 12 steel needles 12 cm. long containing 10 cm. of radon each, in glass capillaries 2 cm. long, through the tumours and under the adjacent skin of the breast. These needles were in for 60 hours, but each needle was withdrawn 2 cm. at intervals, so that each intensely radiated six areas, or 72 in all. At the same time three tubes with walls of 1 mm. thickness of brass with extension wires screwed into one end of each tube were similarly inserted into the axilla for 60 hours, each tube being withdrawn into three different positions. The ulcerated area was treated by surface application on May 4th and 5th, 1924. On the last date, when a total dose of 90·6 mcd. had been given, I removed the breast and axillary glands, and succeeded in covering the raw area with skin. The patient was very prostrate for about a fortnight after the combined treatment. About the end of this period a great deal of pus formed under the skin, small areas of which sloughed. Undoubtedly, in her debilitated condition from cancer, sepsis, and pain, her skin, particularly where unprotected by masses of malignant tissue, was unable to stand the beta ray treatment which had been administered. Though the pus formation practically ceased and the ulcers were healing, she gradually lost ground and died with increased chest symptoms three months after treatment.

This patient was a hopeless case from the beginning on account of metastases in the thorax, but would have probably benefited more by a less drastic radium treatment with gamma rays alone, administered at intervals, and a more limited operation. One is handicapped in such a case by the fact that the prolonged treatment is not always possible for a country patient in a general hospital.

Conclusions.

Experience appears to show that when operation and radiation are combined in the treatment of cancer: 1. There is no advantage in giving a lethal cancer dose of radiation first and delaying operation more than a week, as further delay increases the difficulty of the operation and the shock. 2. Over-radiation of a cancerous mass which cannot be completely removed, followed immediately by its partial removal, lessens the shock, and the operative difficulties. 3. At the operation it is an advantage to bury radium tubes and needles in the incised area and in the paths of dissemination. 4. It is an advantage to radiate the whole operation and suspicious area about three weeks after operation when the incisions have soundly healed. 5. The patient's general condition is the best guide to the extent of the operation and the intervals of time at which different areas are to be efficiently radiated.

WIGAN INFIRMARY.—New X ray and sunlight departments were opened at Wigan Infirmary by Dr. Robert Knox, director of the electrical department of the London Cancer Hospital, on Nov. 16th. In the absence of the President of the institution, the Earl of Crawford, Mr. William Johnson, J.P., Chairman of the board of management, presided. Dr. Knox said that to get the best possible value from X ray examination it was essential that the radiographic outfit should be one of the highest standard. That was provided in the splendid equipment of the radiographic room. For the examination of injuries immediately after, and for observation, at a later date, of the progress of the condition and for the guidance of the orthopædic surgeons, the highest standard of radiographic work was demanded. Expert skill in interpretation was also essential, and the after-treatment of cases of injuries of bones and joints had been provided for in the light and massage department. Nothing in the scheme of the new department seemed to have been overlooked. Prior to the opening ceremony Dr. Knox was entertained to luncheon by the honorary medical staff of the infirmary, when Dr. E. H. Monks, J.P., honorary consulting surgeon to the institution, was in the chair.

TREATMENT OF DIABETES IN CANADA AND THE UNITED STATES.

BY LESLIE J. WITTS, M.B., CH.B. MANCH.,
DICKINSON TRAVELLING SCHOLAR, UNIVERSITY OF MANCHESTER.

A REVIEW of present theory and practice in the treatment of diabetes in Northern America may not be without value in showing fresh aspects of this interesting disease. No single scheme of treatment has been adopted as a standard, and the different methods employed illustrate differences of opinion as to the real nature of the disease. The most striking thing in diabetes is undoubtedly the loss of the power to deal with glucose. The main point at issue is whether insulin is required only for the metabolism of glucose, or whether it is required for the metabolism of fatty acid also, and possibly for other processes in the organism; and the essential conflict of opinion is over the relative importance attached to restriction of the glucose metabolism alone or to restriction of the total metabolism—total food intake and body-weight.

A brief discussion will be given of recent work, which shows that by scientific planning of the diet we can safely reduce the glucose metabolism far below the level attained by simple carbohydrate deprivation. For any given number of food calories required we can calculate the minimum amount of glucose that can be given without the formation of harmful waste products from incomplete combustion of the fat, and this is, in fact, the method by which the diet is usually planned in America. Within the limits set by the total calories and the necessity for a minimum quota of glucose, we can in addition devise diets of varying glucose content while maintaining the same calorific value. It is, therefore, possible to test the rival theories by noting the amount of insulin required to keep a stable diabetic patient sugar-free on diets designed to isolate such factors as variation in the total calories with constant glucose content, or variation in the glucose content with constant calories. It will be seen that the results obtained contradict the belief that diabetes is a disease of glucose metabolism alone.

I have been associated with Dr. F. M. Allen, and it is natural that a bias in his favour should appear. Allen's methods have undergone modification, but the principle of restriction of the total calories remains fundamental. The advent of insulin removed the necessity for the extreme degrees of undernutrition which were considered advisable in severe diabetes and which may often have actually reduced the tolerance. Starvation and emaciation are no longer practised, and Allen now stands in a middle position between rather widely divergent schools of treatment. It must be emphasised that whatever the differences in dietary regulation a normal blood-sugar and a sugar-free urine are regarded by all as essential end-results of treatment. Very little reference is made to insulin in this paper; it is assumed that insulin is given in the necessary dosage whenever these end-results cannot be obtained by an adequate diet alone. It will be convenient to discuss first the total food allowance and secondly the composition of the diet.

Total Food Allowance.

Woodyatt [1] believes that the endocrine function of the pancreas has to do with the utilisation of glucose and nothing else. Allen [2] states that the most important factor governing the insulin requirement, with any ordinary plan of diet, is not the carbohydrate content but the total caloric content. In the Woodyatt scheme the total calories of the diet are determined by the quantity of glucose the patient can assimilate. The quantity of glucose a patient can assimilate is a highly speculative factor. It is affected by the state of nutrition and treatment and, except in total diabetes, by the amount of glucose administered. Glucose may be derived from all three elements in the diet. Carbohydrate produces roughly its own weight of glucose; protein produces 58 per cent. of its weight glucose and the equivalent of 46 per cent. of its weight of fatty acid; fat produces 10 per cent. of its weight glucose from its glycerol fraction and 90 per cent. fatty acid. Fat has the highest calorific power, but the need of carbohydrate for its complete combustion sets an upper limit to the amount that can be given; protein is an indispensable food. Within these limits it is possible to devise any number of diets with the same glucose content but very different caloric values. If diabetes were a disorder of glucose metabolism alone, we should naturally plan a diet containing the maximum number of calories compatible with the glucose tolerance. It is easy to test Woodyatt's hypothesis by giving a stable diabetic patient diets of the same glucose content but different caloric values and observing the insulin requirement. It is, however, the actual food metabolised with which we are concerned and not the food eaten.

Let us suppose that a patient has a glucose tolerance of 100 g. and a weight of 60 kilos. If a gramme of protein is given per kilo of body-weight, the largest diet possible will contain 52 g. carbohydrate, 60 g. protein, 134 g. fat, 1622 calories. The same amount of glucose would be contained in 66 g. carbohydrate, 60 g. protein, 504 calories, but on this allowance the patient would burn not only some of his own fat, which would affect the experiment very little, but some body protein in addition. This would yield extra sugar and the deductions would be false.

Experiments have been made by Allen [3] in which this fallacy is guarded against, and it has been definitely shown that on isoglucogenetic diets the insulin requirement is directly proportional to the total calories. Increase in calories causes increase in body-weight, and this is probably the essential cause of the increased insulin requirement. It is illustrated in the following case:—

—	P., g.	F., g.	C., g.	Calories.	Insulin daily.	Weight in pounds.
March 18th–31st	60	262	100	3000	40	113
April 1st–3rd ..	60	362	90	3860	40	114
Same diet till—						
June 1st–2nd ..	60	362	90	3860	80	133

Restriction of the total calories has, therefore, been generally adopted. The privations of the war caused physiologists to devote more study to undernutrition, and the subject has been recently reviewed by Lusk.[4] If undernutrition is not carried to the prelethal stage its most striking result is a decrease in the basal metabolism. This is well exemplified in the torpor of anorexia nervosa. It is out of proportion to the loss of body-weight and seems to be a protective response of the body to starvation.

During Levanzin's fast the basal metabolism fell from 1432 at the start to 1002 on the twenty-first day. His metabolism thus produced 30 per cent. less heat than at the start, though he had lost only 16·7 per cent. of his body-weight. A group of athletic young men were taking 3200 to 3600 net calories a day. They were then placed on a diet of 1400 calories for three weeks without reducing their mental or physical activities. After the average weight had fallen 12 per cent. below its original level it was found that they were able to maintain this weight on a diet of 1950 calories, a little more than half of the amount originally required. There was a falling off in strength and vigour, but on account of their lower weights they were able to walk a mile with less expenditure of energy than at the beginning of the experiment.

There is thus a simple explanation for the benefits of undernutrition in diabetes. With the loss in body-weight and the decrease in metabolism the diabetic organism is able to support life on a lower plane of nutrition. A diet sufficient to maintain this level is within the tolerance of the pancreas, and there is, moreover, a gain in tolerance when the pancreas is relieved of the strain of constant hyperglycæmia. If the tolerance is very poor, insulin is needed in

addition to maintain a level of nutrition compatible with a full life. Allen [2] argues that undernutrition has a specific effect in diabetes apart from decreased metabolism and relief from hyperglycæmia.

The Toronto school [5] believes that the patient should be kept at 10 per cent. below his normal weight. Others use a calculated value for the basal metabolism in estimating the total calories. The usual method is described by Wilder.[6] The basal metabolism is calculated from the patient's height, ideal weight, age, and sex by the Dubois standards. If the actual basal calories are allowed for a hospital patient, and an additional 20 to 30 per cent. for a patient in a sedentary occupation, it is believed that the food intake is about 20 per cent. below the normal requirement. This undernutrition should lower the metabolic rate of the patient about 15 to 20 per cent. below that of an individual of like surface area, age, and sex on an unrestricted diet, and a constant weight should be maintained.

These methods are very simple and practical but they are much too inelastic. Many patients so treated are overfed and insulin is required by patients who would be happier without it on a lower plane of nutrition. The wide variations of weight in healthy people of the same height are well known, and there is no reason to believe that the normal weight of the diabetic is more standardised. In general we estimate the weight in health too high. The New York Life Insurance Company's figures [7] show that average weights at the age of 45 have a mortality 5 per cent. above the optimum rate, which is found at 20 lb. under the average weight. The ideal weight for a diabetic patient can only be found by observation of the effects of treatment. Joslin and Allen maintain him at the least weight at which he is able to do his work and "feel good." Many youthful patients need building up; the majority of older patients need reduction. Reduction is spaced over long periods by giving diets of 600 to 1000 calories with fairly liberal protein (60–100 g.) and carbohydrates (40 to 100 g.). Allen gives thyroid quite freely in these cases and considers that there is no danger of aggravation of the diabetes if toxic manifestations are avoided. There is no loss of body nitrogen and the diets can be made satisfying. Obese patients often appear to have a severe diabetes, the blood-sugar is over 400 mg. per cent., and ketonuria may be present. When the weight has been reduced the tolerance is found to be quite high and a diet liberal in carbohydrate can be given.

The weight is the most important single factor in diabetes. A physician suffering from diabetes, when asked what diet he was taking, said, "I keep my weight at about 128 lb." The weight is kept constant at the optimum level, the calories vary somewhat with the degree of activity. In experiments where dogs were fasted and exercised, Anderson and Lusk [8] found that the basal metabolism was determined by the condition of the body and was not affected by a large influx of food on the day previous. Similarly, extra food used by the diabetic in exercise and not stored in the organism rarely causes much increase in insulin requirement. Diabetics need not give up arduous occupations on account of the disease, and the majority are benefited by exercise.

In a few cases, however, the tolerance is so poor and the transitions from hyper- to hypo-glycæmia are so sudden and alarming, that the patient can only be balanced on a low diet which is insufficient for an active life. Fortitude is needed in the handling of these cases of "total" diabetes, especially when they occur in children. They should never be given up and allowed to spill sugar in the urine. The insulin may have to be given as often as six times in the 24 hours, and temporary undernutrition may be advisable. It is usually most convenient to keep the carbohydrate low, while a high proportion of fat in the diet seems to buffer the organism against insulin shock. With care the tolerance generally improves markedly and a more natural life can be resumed.

A rather long section has been devoted to the total food intake. It is not disproportionate, because the weight and the total calories are the most important factors in the disease. Diabetes should not be treated by simple carbohydrate restriction, however simple it may seem. The weight and the total calories should be reduced, and though carbohydrate restriction is of prime importance, restriction of fat is also necessary in the obese patient on account of its great calorific power.

Diet Composition.

The so-called Shaffer ratio has very greatly influenced methods of composing diabetic diets in America. It is well known that fat is incompletely metabolised in carbohydrate starvation—"the fats are burned in the fire of the carbohydrates." On the basis of experiments in vitro and metabolism studies on patients, Shaffer [9] believes that two molecules of fatty acid can be completely burned during the oxidation of one molecule of glucose. In practice ketonuria appears when the proportion of fatty acid metabolised exceeds one molecule for every molecule of glucose on account of unequal distribution of the metabolites in the organism, but no severe ketosis develops until the proportion exceeds two molecules of fatty acid to one of glucose. We have stated above that while carbohydrate yields only glucose in the organism, protein and fat yield definite amounts of glucose and fatty acid. For a given number of calories it is therefore possible to calculate a diet containing the maximum amount of fatty acid and the minimum of glucose. From the equimolecular ratio (fatty acid molecules : glucose molecules = 1) Woodyatt [1] has devised the equation

$$F. = 2\,C. + \tfrac{1}{2}\,P.$$

—i.e., the weight of fat may equal twice the weight of carbohydrate, plus half the weight of protein. From the higher ratio (fatty acid molecules : glucose molecules = 2) Wilder [6] has devised the equation

$$F. = 4\,C. + 1{\cdot}4\,P.$$

The Woodyatt formula is more popular, for the Wilder formula gives a dangerously high proportion of fat. Insulin patients may rapidly develop acidosis as a result of infections or indiscretions, and the liability is greater when the patient is constantly on the threshold of ketosis.

The amount of protein is usually determined arbitrarily. Woodyatt gives 1 g. per kilo body-weight; Wilder, and Newburgh and Marsh [10] give $\frac{2}{3}$ g. There is a certain amount of evidence that protein is harmful in diabetes, though Allen absolutely denies this. The Sage investigators [11] and workers at the Mayo Clinic reported their highest D : N ratios during periods of high protein feeding. Wilder and co-workers found that the same dose of insulin, given to a diabetic patient at one period when the diet contained a high proportion of protein, caused much less reduction of glycosuria than it did at another when the protein was largely replaced by carbohydrate, the caloric and total glucose balance of the diet being kept the same. McCann,[12] therefore, gives the minimum amount of protein with which it is possible to keep the patient in nitrogenous equilibrium. Dr. R. R. Hannon tells me that with patients on diets of basal calories plus 10 per cent. (1800 calories) composed on the Woodyatt formula the nitrogen metabolism can be reduced to 2 to 3 g. per day; the sugar is easier to control, but the patients feel weak on so little protein. Allen has published experiments where the replacement of protein by equivalent amounts of carbohydrate has *increased* the insulin dosage, and a deleterious influence from protein is far from certain. Protein is more satisfying and it produces a greater sense of well-being than other foods, and it should not be needlessly restricted.

However the proportions of protein and carbohydrate are manipulated, the real aim in using the Shaffer ratio is to give as little glucose-forming food as possible. On Wilder's scale a man 5 ft. 10 in.

in height and 140 lb. in weight would require a diet of 2100 calories, which would be furnished as 45 P., 33 C., and 199 F. The Woodyatt ratio would allow 60 P., 72 C., and 174 F. A normal individual of the same size would take 120 P., 500 C., and 60 F. (3000 calories). The first difference from the normal is the decrease in total calories, the second is the disproportionate decrease in protein and carbohydrate and the increase in fat. It is impossible to construct pleasant diets when so many calories are derived from fat, and as the insulin dosage is governed by the total calories a very high proportion of fat is not such a desideratum. It is still necessary to reduce the carbohydrate and protein intake, just as we eliminate sugar and all concentrated carbohydrates from the diet, for these foods cause an immediate rise in the blood-sugar. But fat has an effect, less obvious and immediate, on the insulin dosage, and experience shows that diets composed on the above formulæ may finally call for as much insulin as isocaloric diets with more carbohydrate and protein. The ingestion of fat has little immediate effect on the blood-sugar, but when there is a high proportion of fat in the diet the blood-sugar may slowly rise for some months even though weight is not gained, and it is not till the end of this period of stabilisation that the real insulin requirement is known.

Joslin and Allen, therefore, give rather more liberal allowances of protein and carbohydrate than are suggested by the Shaffer ratio. "In average cases comfort, strength, and convenience are served by allowing in the neighbourhood of 100 g. carbohydrate and 100 g. protein daily, and any excessive insulin dosage is avoided by restriction of fat and total calories."[3] These diets certainly entail a higher initial insulin dosage than an isocaloric diet containing more fat, but it is rarely much higher in the long run. It may be necessary to follow patients over rather long periods to see the full effect of fat and total calories on the insulin requirement—often loosely called a loss of tolerance. These points are illustrated by data from Dr. Allen's cases which have been collected by Dr. Garfield G. Duncan.

Of 64 insulin patients followed for two years 39 showed a decreasing insulin requirement, two discontinuing its use, eight showed an increase, and 17 were unchanged since discharge. Of the eight taking more insulin, four were on high fat diets, three showed a considerable gain in weight, and the remaining patient had received a diet increase from 1000 to 2400 calories.

Case 1940 may be reported in greater detail, as the patient was employed in hospital and treated under ideal conditions; there were no intercurrent infections and the weight was kept at 108 to 110 lb. throughout. A diet of 70 g. protein, 60 g. carbohydrate, and 1600 calories, with 60 units of insulin daily, controlled the diabetes from Oct. 6th to Oct. 19th, 1924. Carbohydrate and protein were then reduced to 30–30, the total calories being unchanged. The insulin was reduced to 14 units with moderate hyperglycæmia but no glycosuria. To keep the weight constant and thus exclude any influence of weight on insulin requirement, fat was increased on Nov. 30th to bring the total calories to 1800. There was a gradual increase in the insulin till he was taking 46 units a day. On March 1st, 1925, the protein was increased 10 g. with no change in total calories, the necessary reduction being made in fat. On March 6th he had a hypoglycæmic reaction and the insulin was reduced to 42 units. Gradual increases were then made in protein and carbohydrate with no change in total calories, until on August 14th he was taking 60 P., 60 C., and 1800 calories. Insulin was further reduced to 40 units daily and he remained balanced on this régime. Thus when time was given for stabilisation on isocaloric diets, 60 P. and 60 C. actually required a little less insulin than 30–30 and higher fat.

It is clear that the insulin dosage depends on the total food intake and that fat may ultimately have almost as much influence as carbohydrate. In practice it is necessary to restrict the carbohydrate because of its immediate effect on the blood-sugar, but there is no advantage in reducing it to the lowest possible figure.

The idea of high carbohydrate diets has been pushed to an extreme by Sansum.[13] Whereas the usual diabetic diet contains 2 to 2·5 g. of fat to every gramme of carbohydrate, Sansum's diets contain adequate protein and 2 to 2·5 g. of carbohydrate to every gramme of fat. The insulin requirement is usually increased, but to a far less extent than might have been anticipated. One case is reported in full.

On a diet containing 200 g. of fat this patient gradually lost tolerance till he needed 30 units of insulin daily. When the fat in the diet was reduced to 117 g. and replaced by an isocaloric amount of carbohydrate, so that he was taking 278 g. of carbohydrate a day, the insulin requirement at once increased to 112 units. It then slowly declined, and at the end of some months he needed only 34 units per day. Intercurrent infection cannot be excluded as Sansum does not mention this possibility.

He concludes that on isocaloric diets the insulin requirement increases as the carbohydrate is raised, but not in proportion to the glucose as was formerly believed. Calorie for calorie, glucose requires more insulin than fat, but gramme for gramme it requires less. Successive diets and dosage from another patient were—

C., g.	P., g.	F., g.	Calories.	Insulin.
77	65	182	2206	68
179	82	85	1809	73

These carbohydrate-rich diets are more palatable and the patients feel stronger and are less tempted to break diet. Sansum's reported cases seem to have been mild. In the severe forms of the disease such large amounts of carbohydrate produce excessive fluctuations in the blood-sugar and are quite inadvisable.

Interesting work has been done on artificial foodstuffs. It is probable that any food, just because it is a food, must ipso facto cause a demand for insulin. Certain of these substitutes, such as glycerol, lævulose, caramel, and hexose-phosphates, are known to produce glucose in the body and need not be considered further. Rabinowitch[14] has recently experimented with dihydroxyacetone ($C_3H_6O_3$), which polymerises into glucose ($C_6H_{12}O_6$). In short experiments it causes less hyperglycæmia than an equivalent amount of glucose and seems to accelerate the metabolism of carbohydrate, but there is not evidence that it has any advantage over longer periods.

Kahn[15] in 1923 introduced an artificial fat, intarvin. It is the glycerol fat of margaric acid ($C_{16}H_{33}COOH$), and its importance is that it contains an odd number of carbon atoms. The ordinary fats we eat contain an even number of carbon atoms. In the body fats are oxidised at the β carbon atom, losing two carbon atoms at a time

$$(R.\overset{\beta}{CH_2}.\overset{\alpha}{CH_2}.\ COOH \longrightarrow R.CO.CH_2.COOH \longrightarrow R.COOH + CH_3.COOH).$$

All the common food fats thus finally descend to the four carbon atom stage of butyric acid ($CH_3.CH_2.CH_2.COOH$). In the absence of carbohydrate metabolism, as in starvation or diabetes, the oxidation of this acid stops at aceto-acetic acid ($CH_3.CO.CH_2.COOH$) and ketosis occurs. When intarvin is given no such ketosis can arise. Nevertheless, although intarvin can be completely burned in normal metabolism, it produces an acidosis in the absence of carbohydrate metabolism. The fatty acid is again oxidised two carbon atoms at a time till it comes to the three carbon stage of propionic acid ($CH_3.CH_2.COOH$). Oxidation then stops at the derivatives of this acid, which are pyruvic acid ($CH_3.CO.COOH$) and lactic acid ($CH_3.CHOH.COOH$), and these acids are excreted in the urine. Intarvin is so nauseous that it is difficult to eat it for long periods, and we are not well informed as to the degree of this failure of oxidation or the possibility of a pyruvic acid acidosis, though it is suggested that the CO_2-combining power of the blood may be diminished. It is an extremely valuable substance for studies of the intermediary metabolism and its possibilities have not yet been fully explored.

Such studies might modify present-day views of ketogenesis.

This description of intarvin is based on Lundin's [16] experiments. Keefer's [17] tables likewise show very little decline in organic acid excretion when intarvin is substituted for ordinary fat.

Conclusion.

It has been the object of this paper to reveal the point of cleavage between two widely different interpretations of the disease diabetes. For Woodyatt diabetes is a disease of glucose metabolism understood in its proper sense and only the metabolism of glucose asks for insulin. For Allen diabetes is a disease of total metabolism, and all foodstuffs, whether of the nature of glucose or fatty acid, cause a demand for insulin both in their catabolism and anabolism. This suggests that all foodstuffs pass through a final common stage where insulin is demanded. The diffusion of insulin through all the tissues, and the dependence of insulin dosage on the body-weight and the total food intake, make it appear most likely that insulin is necessary, not merely for the metabolism of glucose, but for the process of metabolism itself.

Clinical and Laboratory Notes.

A CASE OF DOUBLE INTESTINAL OBSTRUCTION.

BY L. F. O'SHAUGHNESSY, F.R.C.S. ENG.,
SUDAN MEDICAL SERVICE.

A Sudanese woman, aged 50, was admitted to Makwar Civil Hospital with a history of three days' severe abdominal pain. During this period she had not vomited nor had her bowels moved. The woman was moribund; her breath smelt of acetone, and there was marked abdominal distension. The following were the findings at an autopsy two hours after admission:

Coils of distended small intestine and a very distended cæcum and ascending colon were displayed on opening the abdomen. On further examination the terminal six inches of the ileum were found to be collapsed, as complete obstruction had been produced by a tight fibrous band which passed from the posterior abdominal wall across the gut to the mesentery. Some adhesions were also present in the region of the duodeno-jejunal flexure and a traction diverticulum of the jejunum had resulted. The cause of obstruction in the large intestine was found to be an annular growth of the hepatic flexure which completely occluded the colon.

A report on this tumour, by Major T. N. Whitehead, described it as a columnar-celled carcinoma.

There appear to be three points of interest in this case: (1) The absence of vomiting, associated with a tightly contracted ileo-cæcal sphincter. (2) The lesson that blind cæcostomy would have been useless. (3) The occurrence of intestinal carcinoma in a person living a very primitive life on a diet unaffected by modern methods of food preservation or adulteration.

AN UNUSUAL CASE OF REMOVAL OF THE COLON

BY S. A. LANE, M.D. DUB.,
SURGEON, BOGNOR WAR MEMORIAL HOSPITAL.

THE following case seems sufficiently uncommon to justify its being recorded.

The patient, an unmarried woman of 50, was admitted to hospital in a state of profound collapse. She had been seized with agonising pain a few hours previously, quickly followed by vomiting and collapse. A hypodermic injection of morphine was given, and she was taken at once to hospital, where resuscitation measures were employed.

On examination a tumour was found extending nearly up to the umbilicus; this was thought to be a twisted ovarian cyst. The patient was very thin and gave a history of long-standing attacks of pain, constipation, and frequent vomiting.

On recovery from the severe collapse the abdomen was opened under spinal analgesia and a large black mass immediately seen. Examination of the pelvis showed a normal uterus and normal appendages. The small intestine was seen to pass into the tumour, which was tethered to the posterior abdominal wall by a stout pedicle which was tightly compressed by a band which could be readily felt. Emerging from the black mass was large intestine which proved to be the sigmoid colon.

After dividing the constriction surrounding the pedicle the state of affairs became clear. The bowel, from the last six inches of the ileum to the termination of the descending colon, possessed a very long mesentery, which had permitted strangulation of the entire segment of intestine by a band originating from the healthy colon below the strangled segment. This band probably arose from an appendix epiploica, and its ultimate attachment could not be made out.

As it was certain the injured intestine was beyond recovery there was no choice as to procedure. Accordingly the entire segment of intestine was resected, the ends closed, and the ileum implanted into the sigmoid by lateral anastomosis. The operation was easy owing to the long mesentery, which did away with the need to mobilise the colon, and to the ready access to the blood-vessels in the mesentery.

The patient's condition was critical, and had it not been for the spinal analgesia it is thought she would have succumbed. She remained in hospital eight weeks, during most of which time diarrhœa was extremely troublesome. This cleared up and convalescence was uneventful thereafter.

The operation was carried out in September of 1924. The patient is now an active and well-nourished looking woman in striking contrast to her previous condition.

TWO CASES OF SUICIDAL CUT-THROAT.

BY SYDNEY SMITH, M.D., D.P.H. EDIN.,
PRINCIPAL MEDICO-LEGAL EXPERT, EGYPTIAN GOVERNMENT SERVICE.

IN cases of death from wounding, medical evidence frequently becomes of paramount importance in deciding whether the wounds were of homicidal, suicidal, or accidental nature, for it often happens that no evidence is available other than that gained from an examination of the body and the locus. In view of the responsibility placed upon the medical examiner, it is desirable to record cases in which the

injuries of the victim are of an unusual or unexpected nature, and I think it worth while to report the two following cases of suicidal cut-throat which present widely different characters.

CASE 1.—An Austrian subject, 55 years of age, was discovered lying on the floor of his room with a razor by his side. A letter was found stating his intention to take his own life because of ill-health and poverty. The deceased was right handed.

On examination the only injury found was a superficial wound one and three-quarter inches long on the right side of the neck behind the level of the sternomastoid muscle and about the position of its lower third. The wound had a clean-cut sliced appearance and was directed from above downwards and forwards. It passed through the skin and subcutaneous tissues and incised the wall of the external jugular vein forming a small slit a quarter of an inch long, just above the omohyoid muscle. There was no effusion of blood into the tissues, nor was there any other sign of violence. A few bubbles of air were found in the right auricle of the heart but nothing suggestive of the usual frothy appearance of air embolism. There was no air in the ventricle nor in the pulmonary artery. There was a considerable amount of blood in the heart and vessels, and the condition of the body did not suggest death from hæmorrhage. Both lungs showed advanced tuberculosis and the kidneys subacute interstitial nephritis.

The case has a certain medico-legal interest. In the first place the selection of a site behind the sternomastoid is very unusual, as is the position of the wound on the right side in a right-handed man. The superficial nature of the wound is also remarkable as it would scarcely have been imagined that a person intent on self-destruction would have satisfied himself with such a superficial incision. Death was no doubt partly due to hæmorrhage, partly to embarrassment of the heart produced by the entry of a few bubbles of air.

CASE 2.—An adult male Egyptian was seen to cut his throat in the street, after which he staggered along for about 50 yards and fell dead. On examination seven transverse wounds of the throat were found. These were all superficial and separate on the right side of the neck but joined together into one deep incision on passing to the left. Three of them, deeper than the others, started behind the level of the right sternomastoid; the other four, which were lower down and much more superficial, commenced midway between the sternomastoid and the middle line. They all passed almost horizontally across the throat and ended in a jagged incision on the anterior margin of the left sternomastoid.

Considerable damage was done to the deeper tissues of the neck and in the cartilaginous structures four well-defined incisions were observed. The highest of these passed horizontally through the thyroid cartilage and completely divided the larynx. The second passed completely through the larynx between the thyroid and cricoid cartilages. The third passed through the middle of the cricoid in the same horizontal plane as the others. The fourth passed through the lower part of the cricoid in front, but sloped downwards at an acute angle and reached the upper rings of the trachea posteriorly. This incision cut the left common carotid artery and the left internal jugular vein. There was also a superficial cut on the right wing of the thyroid cartilage which could be produced only by a cut commencing on the right and indicated that the victim was left handed.

Other structures divided included the thyroid gland in two places, the superior thyroid artery and the cricothyroid branch, and the sternohyoid, sternothyroid and omohyoid muscles, while the sternomastoid muscles on both sides were severely injured.

These two cases illustrate vividly the extreme difference which may be found in suicidal wounds. In the first the injury was of such slight extent and was in such an extraordinary position that the suggestion of suicide might not arise, while the second shows such excessive violence that it might readily be assumed that the case was one of murder. No doctor experienced in medico-legal work is likely to make a statement that such injuries were certainly self-inflicted or otherwise, without more evidence than is forthcoming from the examination of the injuries alone, but there is a tendency for medical men of less experience in these matters to be more dogmatic, and I trust that the publication of cases similar to the above may induce caution in giving a definite opinion as to whether a given wound is of a suicidal, homicidal, or accidental nature.

Medical Societies.

ROYAL SOCIETY OF MEDICINE.

SECTION OF MEDICINE.

DISCUSSION ON THE DIAGNOSIS AND TREATMENT OF COLITIS.

A MEETING of this Section was held on Nov. 23rd, when Dr. HUGH THURSFIELD, the President, took the chair, and Dr. ARTHUR HURST read a paper on this subject, which appears on p. 1151 of this issue of THE LANCET.

In the discussion which followed, the PRESIDENT said that in many years' experience he had never heard such a sane and clear address on a difficult subject. He agreed that many physicians had never seen what happened in a case of colitis, because they did not use the sigmoidoscope. He would extend Dr. Hurst's remarks on the bacteriology of intestinal diseases so as to include practically all intestinal infections, with the exception of such specific conditions as typhoid. Bacteriologists, radiologists, and clinicians appeared to have lost their heads on this subject during the last few years, and his hope was that Dr. Hurst's address would do much to bring the profession back to its moorings. With regard to the use of antidysenteric serum, for some years he had noted a group of infants who, particularly in the summer and autumn, had very violent attacks of diarrhœa, with high fever; several years ago he had concluded that these attacks were probably dysenteric, and in his ward at the Children's Hospital antidysenteric serum was at once given to cases showing these symptoms. The bacteriology was investigated afterwards, and in a fair proportion some types of dysenteric organisms were isolated. He was sure this course had saved the lives of many infants.

Dr. WILFRID EDGECOMBE thought that the main reason why Dr. Hurst had been able to be so precise in his generalisations was that he had long used the sigmoidoscope as a routine. It should no longer be regarded as an instrument for the surgeon alone. Referring to so-called muco-membranous colitis, Dr. Edgecombe agreed that there was no evidence of a true inflammation of the colon. "Colonic mucorrhœa" would better describe the condition, for it was purely a secretory neurosis, causing an excessive outpouring of mucus, to the accompaniment of colicky spasms; it was more common in psychasthenics than in neurasthenics. In comparing it with asthma Dr. Hurst had been very apt. Sometimes the mucous casts were very large, but usually there was no membrane; a few epithelial cells were present and some leucocytes, but practically never pus. Normal denizens of the alimentary tract were very numerous in these casts. Infection, he thought, was only secondary in this condition, but probably some intestinal toxæmia followed the retention and decomposition of the large collections of foul-smelling mucus. The effect of this on the nervous system made the patient worse. The subjects of colonic mucorrhœa were querulous individuals whose attention was focused on their abdomen; they had a muddy complexion and lustreless skin. They were constipated, and usually had run the gamut of aperients, which acted as irritants and perpetuated the excessive secretion of mucus, Nature's answer to the irritation. The attacks of colicky pain were due to a local spasm in the bowel. Many of these patients had visceroptosis, and presented the signs of what Dr. Robert Hutchison called "the chronic abdomen." Some had had the appendix removed, but without mitigation of the symptoms. He differed from Dr. Hurst about lavage of the colon for these cases; he thought it was good treatment. Every case demanded consideration of: (1) the local abdominal condition, (2) the general somatic neurasthenia, and (3) the mental condition, which was usually at the bottom of the whole trouble. He stopped aperients

and put patients back on to ordinary diet excepting fibrous vegetables. Usually they had become diet-faddists. Colonic lavage was done on alternate days, the fluid used being the equivalent of normal saline, made isotonic with the blood, and heated to 102° F. Forty ounces of this was allowed to enter the rectum at low pressure—i.e., from a height of 18 inches. After two or three applications large quantities of mucus came down, which had probably been clinging to the intestinal wall. Douches caused a speedy improvement in the patient. A good diet was given and massage and exercise ordered; to deal with the mental distortion it was necessary to persuade the patient that the secretion of mucus was normal and that there were better objects of interest than abdominal symptoms and evacuations. Among drugs he found most benefit from bromide, belladonna, and valerian; of the last named he used not less than a drachm of the ammoniated tincture. These drugs were very beneficial in moderately severe cases. Some of the serious cases seemed quite hopeless, and drifted into a state of hypochondriasis, and might even end in a mental institution.

Prof. L. S. DUDGEON commented on the frequency with which radiologists diagnosed colitis on the X ray picture. Evidence in favour of colitis was the discharge of leucocytes, pus, and epithelial cells from the rectum. Manson-Bahr and others had shown that when ulcers were seen with the sigmoidoscope, scrapings might reveal the organism when it had not been found by other means. He agreed with what Dr. Hurst had said about the bacteriology of the fæces. The fæcal flora varied considerably in healthy people according to the diet they happened to be taking. Extraordinary results were seen to follow gross dietetic errors. Very often a diagnosis of colitis was made on the strength of such unusual flora, partly induced, perhaps, by the use of various purgatives. He considered that ulcerative colitis could be put into three groups: (1) amœbic; (2) those due to the Shiga and Flexner group of organisms; and (3) those in which no Shiga or Flexner organisms could be found, an ulcerative colitis showing ulcers of the colon like those of bacillary dysentery. He considered that only two organisms could be regarded as abnormal; they were found in a certain number of cases. One was the *B. coli hæmolyticus;* the other, the *B. mucosus capsulatus*. With regard to the first of these, it was not a question of finding the organism once, but of finding it repeatedly in a patient who was passing blood and pus per rectum and who had ulcerative colitis. In two such patients he had seen very considerable benefit follow vaccine treatment, but only in two. The *B. capsulatus* frequently occurred in large numbers in abnormal conditions of the colon associated with ulceration. He thought that streptococcal invasion had nothing to do with ulcerative colitis.

Speaking of polypoid conditions of the colon, Prof. Dudgeon recognised three forms—true carcinoma of the colon, which caused polypoid growths; genuine adenomata of the bowel, which might or might not be associated with carcinoma; and the form met with in true chronic dysentery and ulcerative colitis—polypoid masses composed of granulation tissue and perhaps covered with mucous membrane. Only two kinds of treatment seemed good—diet and absolute rest. He could not understand there being any value in antiserum treatment of these cases, although admittedly Dr. Hurst had quoted cases in which the patient had markedly improved after it was given. He had never seen it do good in chronic bacillary dysentery, and he had no use for vaccine treatment in ulcerative colitis.

Dr. J. A. RYLE said that he had noticed much benefit from the use of serum and inspection with the sigmoidoscope in the kind of cases being discussed. Patients who had been making no progress for months—some for a year or two—had their symptoms immediately relieved and the appearance of the mucous membrane restored by the use of serum. One female patient, with advanced ulceration of the colon, had been very anæmic and ill, and weighed only 6 st. She had been treated in this way, and now weighed 10 st. and had never felt better. He had not seen the serious condition, polyposis of the colon, in any case being treated with serum, but it had been observed in two cases which had not had serum treatment. He maintained that amœbic ulceration could be diagnosed with certainty by using the sigmoidoscope, sometimes when negative reports came from the laboratory.

Dr. ADOLPHE ABRAHAMS spoke of the variety of conditions sometimes classed as colitis. He remembered cases in which rectal crises, carcinoma, pelvic tumours pressing on the bowel, and abdominal aneurysm had been diagnosed as colitis, simply because there was an abnormal quantity of mucus coming from the bowel. He agreed that mucomembranous colitis was a very definite entity, and one that called for careful consideration and treatment. It was admittedly a neurosis, especially of bowel mechanisms. London practitioners were a good deal debarred from spa treatment for such cases, but they could largely make up for this by using olive oil enemata and belladonna, the latter pushed to the toleration point.

Dr. PARKES WEBER asked whether the polyposis developing in ulcerative colitis was identical with that which followed amœbic or bacillary dysentery. He believed that cases of colica mucosa were now rare, and he regarded them as the result of an abnormal reaction which was found only in certain people. Everybody who indulged in dietary vagaries and neglected to take exercise was subject to abnormalities in bowel conditions and fæces. Muscular exertion seemed to improve the tone and motility of the whole bowel.

Dr. RENE WYBAUW spoke of having often seen the condition known as mucous colitis benefited reflexly by the successful treatment of cardiac irregularities.

Dr. HURST, in reply, expressed his disappointment that no surgeon had participated in the discussion. Medical treatment was satisfactory enough to enable him to say that surgery was seldom necessary. Of the 19 cases he had attended since the war only one died, and she might have died in any case as she had very severe broncho-pneumonia. None of the patients had died of the colitis, nor of indirect results from it, and 17 were still well. As to the treatment of mucomembranous colitis, he agreed with Dr. Edgecombe, but at one time the Plombières treatment had been so commonly used that he had seen it cause colitis when not previously present. Admittedly olive oil enemata were sometimes useful, but the olive oil did not dissolve the fæces. Experimentally, fæces had been placed in three test-tubes and covered with olive oil, water, and liquid paraffin respectively. At the end of 24 hours the fæces in the olive oil were even harder than before; water dissolved them well, and paraffin made a useful difference. Abdominal ptosis he did not consider important; in a series of quite healthy medical students he had found all sorts of abnormalities of position, the man whose viscera were lowest being a first-class forward in Rugby football.

SECTION OF ORTHOPÆDICS.

EXHIBITION OF CASES AND SPECIMENS.

A CLINICAL meeting of this Section took place recently at the Middlesex Hospital, the chair being occupied by Dr. GORDON PUGH, the President.

Rickets with Deformity of Femora.

Mr. E. T. BAILEY demonstrated the case of a male child, aged 1 year 10 months, the subject of rickets, who had an unusual bilateral deformity of the femur. There was a backward curvature of the lower end of the femur, immediately above the epiphysis, of a type which was unusual. The child was fed at the breast for only two weeks immediately following birth; it then had a proprietary milk for five months. At a year old the child had whooping-cough, and other illnesses followed. The other members of the family were healthy. The skiagrams of the case were

shown. The possibility that it was a case of renal rickets had arisen and been discussed, but, so far, no satisfactory specimen of the urine had been obtained, as the child was so young. An effort would be made to do so. He invited views.

Mr. BLUNDELL BANKART said the case came to his out-patient department and showed the evidences of rickets—the square head, the conformation of back and abdomen, the enlargement of the lower ends of the radius, and the crooked legs. But he had not previously seen in association with rickets the fixed flexure at the knees which this patient presented. In some features the epiphysial changes in this patient were not the characteristic ones of rickets, and he thought the trumpet-shaped contour of the extremities of the shafts of the long bones gave it a resemblance to renal rickets. If this was likely to be the condition, it would cause hesitation in undertaking operation for rectifying the deformity.

Mr. W. H. OGILVIE did not regard this as a case of renal rickets, as the change seen at the lower end of the femur did not resemble that of a recent case of renal rickets he showed to the Section. In the latter case the bone presented a more definitely moth-eaten appearance, and the deformity was due to the epiphysis having slipped. The lower ends of the bone showed a trumpeted appearance, but the diaphysis was spread out, and there was a markedly increased density at the lower ends of the bones. The bones in the present child did not show any signs of osteoporosis, such as was evident in his own case of renal rickets, and a further contrast was that this child now shown appeared to be well in general health.

Mr. T. H. OPENSHAW suggested that perhaps this patient had a congenital flexure of the knees, and that the rickets was a superadded condition. It was very unusual to find both knees flexed to an equal degree in a case of recent onset.

Mr. H. A. T. FAIRBANK said that even though the bones of this child were unusually dense, he inclined to regard this case as one of renal rickets; the condition of the lower end of the femur was, he thought, very suggestive of that. It was not a bending, but a fracture at one side of the bone. The dense bone at the surface of the shaft ran into the lower fragment in the way usually seen in renal rickets. The impression he had, based on his experience, was that one did not see juxta-epiphysial fractures unless the child was going down-hill and the bone was atrophic. The prognosis of such was very grave. He had seen two or three cases in which light treatment had definitely cured, for the time being, changes apparently rickety, but not cases which had progressed to the stage of sustaining fracture; they usually progressed downwards to death. If the present case was a renal one, it seemed that the bones had been at one time much less dense than now, and that, therefore, treatment had enabled the child to deal with its condition. He counselled examination of the urine before deciding as to operation.

Mr. BAILEY, in reply, undertook to have the urine examined, and a blood-urea test done.

Coxa Vara.

Mr. FAIRBANK showed the bones from a patient the subject of coxa vara, whom he exhibited at the last meeting of the Section. There was an unusual congenital deformity of the upper end of the femur, coxa vara, and a very short femur, with a bend in it a short way down the shaft. He did an osteotomy on the case, and was proceeding to over-correct the bend in the femur when death suddenly supervened, and no cause for this collapse could be discovered. There was even less than the usual amount of bleeding, and the bone oozed less than was customary; moreover, there were no evidences of shock. At the post-mortem examination the greater part of one lung was found to be indurated by a thrombosis in the coronary vessels. The specimen now exhibited showed that the neck was present and was cartilaginous, but not ossified. He had a similar case in which death took place under the anæsthetic, and there nearly the whole of one lung was an infarct. Neither of the cases was septic, as far as he could discover, and there did not seem to be sufficient shock or bleeding to account for the thrombotic condition. He therefore assumed that the clot began to form in the heart.

Osteomyelitis Variolosa.

Mr. P. J. VERRALL described, and illustrated on the screen, two cases of this condition which had been under his care in the last year. There was osteomyelitis of practically all the bones of the two limbs, including the metacarpals and the metatarsals, with septic arthritis of the elbows and wrists. It could be readily conceived that in the course of such a disease as small-pox there was a great deal of absorption into the bony system generally, with transient arthritis, pains in the bones themselves also being quite common, but actual osteomyelitis in the disease was a comparative rarity. Osler just mentioned it as a possibility. Recently two observers in America recorded what they regarded as the first case of this condition. A skiagram which Mr. Verrall now showed presented sinuses over all the metacarpal bones.

Osteomyelitis of the Clavicle.

The PRESIDENT showed a boy who, in May last, attended hospital for what was found to be osteomyelitis of the clavicle, and an abscess was opened. Last month practically the whole bone was removed without an anæsthetic, and the sequestrum was now shown. The skiagrams showed that the shaft had re-formed; he had not seen this happen before in membrane bone.

Mr. T. OPENSHAW said his experience was that clavicle bone did re-form. In one case he feared the end of the clavicle would collapse, but a new clavicle had formed in two years, very mis-shapen and very thick; but four years later there was a perfect clavicle, both as to shape and thickness. It was an indication that function regulated and determined the ultimate shape of the bone.

Ununited Fracture of Neck of Femur.

Mr. A. H. TODD showed a woman aged 30, who obtained a living by selling newspapers in a street pitch. She related that in March, 1924, she slipped on the snow, the impact being sustained on the left hip. She was treated at a provincial hospital four months by a Thomas splint, and was discharged, using crutches, as there was failure of union, and the shortening was about two inches. After walking a few hundred yards she had pain, and had been compelled to relinquish her work. Opinions as to what ought to be done for her were asked.

Mr. R. C. ELMSLIE said he thought the chance of getting good union in this femur, with such an amount of absorption at the neck was remote; but in a woman of this age the chance of securing reasonably good function was not by any means bad. He advocated removing the great trochanter, with the head of the bone, abducting the limb very widely, and trying to get the neck into the acetabulum, replacing the great trochanter an inch lower down in the shaft. Two years ago he operated on a man of 50 in that way, and though his duties involved climbing up rope ladders on to liners at sea, he had been six months back at work, and seemed to be doing very well. For nine months following operation he kept that man on a calliper splint.

Mr. OPENSHAW agreed with Mr. Elmslie that it was very unlikely there would occur union between the head and the great trochanter, as the surface was rounded off and devitalised. His own feeling would not be to scoop out the head from the acetabulum, though that could be done, but to break off the great trochanter, and put the top of the shaft into the acetabulum. The functional result of that, he thought, would be better than from any other treatment. If there had been fibrous union, a Hessing's splint would have constituted the best treatment.

Spontaneous Fracture through Neck of Femur.

Mr. H. C. EDWARDS showed a boy aged 6 years, who, in consequence of a cyst, sustained a spontaneous fracture through the femur neck. The boy, an only child, had never been strong, and he had been in bed for seven months prior to the hip giving trouble. He had had measles, which led to acute middle-ear disease, and for that the radical mastoid operation was performed. Chicken-pox was his last ailment. A week after his discharge from hospital he was walking in the street when he appeared to twist and crumple up, and was brought to hospital complaining of pain. The X ray showed he had an area of translucency in the neck of the left femur, and this was the site of the fracture. A double Thomas splint, with full abduction, was applied, and the position was maintained for five weeks, the Thomas being replaced at the end of that time by a double long Liston splint, being hinged at the left hip-joint so as to allow of full abduction. The patient was kept off his feet five months, and then was given a calliper splint, and allowed to walk. That splint he was still using. He was seen, by the skiagram, to have coxa vara, with the epiphysial line approaching the vertical. There was now no limitation of movement, except that of abduction, and the trochanter was raised. There was shortening to the extent of ¼ in. to ⅜ in. The problem now was as to how he should be treated for the coxa vara, or, most important, when it should be done. Should some time be allowed so as to see how the cyst remaining would behave?

Mr. ST. J. D. BUXTON said the question was whether all cases of cyst in bones should be operated upon, or whether they should not. He presumed that the purpose of the operation in most of the cases was to establish the diagnosis, though in most instances the skiagram enabled the nature of the disease to be known. There was no microscopical examination in the present case, but he agreed it seemed to be a cyst. It was curious that cysts should gradually become obliterated.

Congenital Malformation of Arm and Eyelid.

Mr. TODD showed a female child aged 6 years, whom he had known since she was a baby. There was a curious lump in the left eyebrow, with vertical grooves down it, while the right arm and hand presented a claw-like deformity. Except by applying splints to endeavour to correct the deformity nothing had been done. Skiagraphy of the skull was not satisfactory; he thought there might be a dermoid pressing on the motor area of the brain, thus causing the upper limb deformity. The question of treatment did not arise in this case, as the child was using her hand and arm, and the mother would not hear of any operative interference.

Deformity of Spine.—Swelling of Ankle.

The PRESIDENT showed two children with deformities of the spine, probably congenital. The first was a boy aged 6, who had only 11 ribs on one side, 12 on the other. His Wassermann reaction was strongly positive. The other, also aged 6, was a case of scoliosis; there was no evidence of rickets. Here also there was a strongly marked positive Wassermann. He had found that Wassermann was more commonly positive among children having congenital bony deformities than among ordinary hospital children. The boy with scoliosis had a double curve, and the heads of the femora did not appear to be calcified.

Mr. ELMSLIE said he recently saw a small boy who had a congenital malformation in the spine, and there were wedge-shaped vertebræ. There was a slight projection backwards at the site of the deformity, and the case had been diagnosed as spinal caries, and, to the distress of the father, a medical man, had been treated as such. It should always be possible to differentiate these cases from caries.

The PRESIDENT showed a boy aged 4 years, who was admitted to one of the London hospitals on account of swelling of the ankle, and was kept there seven weeks. Last January he came under the exhibitor's care in plaster, the diagnosis being tuberculosis of the ankle. When the plaster was removed, it was found that there was full movement, and but little swelling. A month later the ankle appeared to be normal, but a month later still, swelling recommenced, and again it subsided, skiagrams all along being negative. Last September the movements again became restricted, and there was swelling around the internal malleolus, but without undue heat. There was a small hæmatoma in the abdomen, and he thought it might be a case of hæmophilia. When the swelling again cleared, he was allowed to walk, but this caused pain and swelling, and therefore he was taken off his feet once more. The speaker had never known a case of the kind limited to the ankle-joint.

SECTION OF EPIDEMIOLOGY.

A MEETING of this Section was held on Nov. 26th, the chair being occupied by Dr. S. MONCKTON COPEMAN, the President, when Dr. G. F. BUCHAN (M.O.H. for Willesden) opened a discussion on the

HOSPITAL IN RELATION TO PUBLIC HEALTH.

The problem, he said, was a much wider one to-day than 20 years ago, and in order to visualise the extent to which hospital provision was necessary for public health purposes he took as his basis the requirements for an average community of 100,000 people. At the date of the passing of the Infectious Diseases (Notification) Act, 1889, the term infectious diseases was held to include only small-pox, cholera, diphtheria, erysipelas, scarlet, typhus, typhoid, puerperal, relapsing and continued fevers. But to these must now be added cerebro-spinal fever, encephalitis lethargica, acute poliomyelitis and polio-encephalitis, ophthalmia neonatorum, acute primary pneumonia, acute influenzal pneumonia, trench fever, dysentery, malaria, plague, and tuberculosis. Notification implied isolation of the sufferer, but this did not suffice unless there were means provided for the patient to recover. It had been found that for the diseases notifiable under the 1899 Act, one bed per 1000 population sufficed, while for epidemic diseases of the central nervous system the 100,000 people predicated would require one bed, a similar provision being needed for puerperal fever and puerperal pyrexia cases, on the basis of each case lasting six weeks; while for ophthalmia neonatorum one bed was ample. With regard to the acute pneumonias, on the basis of 124 notifications in the 100,000 population, and the admission of 40 per cent. of the notified cases, he would set apart eight beds. It did not seem necessary to make any special provision for cases of trench fever, dysentery, malaria, and plague. Experience with tuberculosis showed the need of one bed for every 1500 of the population, and the inclusion of this among the notifiable diseases had raised many new problems of hospital accommodation. As the tuberculosis authority was not usually either the sanitary authority or the infectious diseases hospital authority, hospital provision for this disease had been generally regarded as a separate matter. There was need for unification here. As regards hospital provision for complicated and uncomplicated cases of confinement Dr. Buchan's experience showed that about 20 per cent. of all confinements would be most suitably accommodated in hospital, and he considered that for a population of 100,000 16 beds for confinement cases were needed. It was not so clear what provision should be made for children under 5 years of age, but, on the figures he gave for Willesden, at least 12 beds would be wanted, and for school medical work 13. Only a small proportion of new cases of venereal disease required hospital treatment, and three beds would probably be found ample. Thus a total of at least 221 beds should be provided for 100,000 people.

Dr. Buchan went on to deal with some pressing public health problems. One of these concerned measles, and he urged that there should be hos-

pital room for severe complicated cases of that disease, and seven beds should be reserved for them. Whooping-cough also, like measles, caused many deaths, and at least four beds should be set apart for complicated cases of it. On the question of cancer of the breast, he pointed out that in Leeds it was found that if operation was performed while the disease was still restricted to the breast, 87 per cent. of the cases were still alive at the end of ten years after the operation; but if at operation the disease had advanced beyond the breast only 5 to 6 per cent. survived for that period. The accommodation for dying cases of cancer was scarcely a public health problem. He saw no reason why a hospital, suitably planned on the pavilion system, should not admit cases of all the diseases for which a local authority could make provision. He favoured a general hospital, with all the necessary special departments. In such an institution research could also very well be undertaken, chiefly, perhaps, in regard to the antecedents of patients coming to the hospital, in efforts to trace the factors influencing the production of the disease conditions; also the results of treatment and the general after-history of the patients.

Discussion.

Dr. T. CARNWATH considered that Dr. Buchan had approached the question from a commonsense point of view, though probably he would admit that some of the estimates given could be revised with advantage. For example, the suggestion of six beds per 100,000 for cases of rheumatic disease must be compared with Birmingham's provision of 100 beds for that disease to serve a population of about a million, and even the 100 were not found to be sufficient. Dr. Buchan's remarks concerning the present development of hospital accommodation would probably be echoed by most members of the Section; few of those engaged in public health work could be satisfied with the present arrangement of hospital provision. It was unsatisfactory to have little maternity homes and isolation hospitals springing up in all sorts of places, having no connexion with any central institution and no facilities for research. Much could be said in favour of the big hospital, such as Dr. Buchan portrayed, though small hospitals might well act as feeders to the larger one. In the matter of such cases as those showing the sequelæ of encephalitis lethargica a wider area must be contemplated. He welcomed the opener's comparison of the State hospital with the voluntary hospital, and it reminded him of the up-to-date equipment and staffing of the municipal hospital in Philadelphia, which he saw on his visit to the States, which impressed him very much. There the whole organisation of the hospital work was under a director of health, and the work was divided into a hospital section and a general section. Not only was the laboratory one of the finest he had ever seen, but the organisation for following up cases afterwards was well worthy of emulation on a large scale in this country, for in Britain among the large numbers being operated upon the after-history was known in only a small percentage.

Dr. J. D. ROLLESTON pointed out that in Paris and a number of other large towns on the continent there were not found special isolation hospitals for children, the pavilions for the treatment of infectious diseases being placed in the grounds of the ordinary children's hospitals. Only for adult cases were special isolation hospitals provided outside the ordinary hospital areas. The treatment of cases of infectious disease in ordinary children's hospitals was a matter of interest, as the best men on the staffs of those hospitals were likely to pay special attention to fever cases, and much valuable work on immunisation had been done in children's hospitals in recent years, especially in connexion with diphtheria and measles. There was great scope for study and research in isolation hospitals, not only in epidemiology, but also pediatrics, general medicine, and the history of medicine.

Dr. HUGH MCEWEN said many felt that in the past too many cases of scarlet fever had been isolated, and that a large number of patients with that disease might well, with due precautions and care, be nursed and treated in their own homes. He did not agree with the idea of some that small-pox cases could safely be treated in the same institution as other diseases, even though, apparently, it was done in Denmark. Dr. Buchan's comments on research work were very much to the point.

Dr. JANET LANE-CLAYPON asked whether there had been any real shortage of beds, and, if so, how severe that shortage was. With regard to cancer, she thought that in a neighbourhood like London theory was hardly likely to accord with practice in regard to the number of beds, because many cancer patients from all parts of England came into London for operation. Roughly, about 50 per cent. of the cancer cases came from outside the metropolitan area, therefore considerable provision had to be made in this respect for cases living outside that area. The proportion of inoperable cases could be altered, because obviously nearly every case was operable at some stage if it could be seen at that stage, and when the proportion of inoperable cases to the total had been reduced more bed provision would have to be made. Inquiry had been instituted as to the amount of delay in the admission of cases of cancer of the breast, and it was found that, for all practical purposes, there was no delay; in 800 cases there was a delay of more than a few days in only two, and in those the interval was purely accidental.

Dr. M. B. ARNOLD spoke of the difficulty of allotting beds to cover seasonal requirements, and said he thought most of Dr. Buchan's observations were founded on the assumption that the demand for beds would be steady month by month. But with regard to diphtheria, which most would prefer to treat in hospital, such a steady demand would not occur. At certain times isolation hospitals were almost forced to overcrowd, while at others the staff had to stand more or less idle. During the slack times the accommodation could be deferred for a time without definite harm to the patient. It seemed to him possible that someone responsible for supervising the needs of a district could smooth out these admission irregularities.

Dr. G. C. TROTTER remarked that Dr. Buchan seemed to include everything in his suggested hospital, so that there would be no need for other kinds. As to the idea of leaving cases of advanced cancer to the guardians, he did not see why that should be done, as there was still held to be a stigma attached to the Poor-law institutions. And if these cases were left at home it imposed a great hardship on the family, and the nursing and attention usually knocked up one or more members of it, even if a district nurse's services were secured to relieve the situation. Altogether he thought Dr. Buchan had made out his case. As time went on perhaps the stigma of the Poor-law would be removed.

Dr. M. RANDALL, speaking as one with experience of a place of about the size Dr. Buchan was dealing with, said it meant that more beds would be required and that opened the question of who would look after them. Sufficient fully trained nurses might be a difficulty; he did not think so-called fever nurses were capable of dealing with general cases, including surgical.

Dr. T. S. MCINTOSH mentioned that for six months he was assistant to Dr. Buchan at Willesden, and said he regarded the paper as very valuable, if only for the figures given of the estimated accommodation required for the various conditions. He had himself seen the hospital in Amsterdam which had been referred to, and was surprised to find that small-pox was being treated in a general hospital. But the medical superintendent had no fears about the spread of the infection to other patients. Yet the small-pox pavilions there were less than 40 feet from the street and from some of the other pavilions. He agreed that the best plan was to have one hospital for all kinds of cases, and it was desirable boldly to proclaim that it was the duty of the community to provide for

everyone in need of medical and surgical treatment who could not afford the usual fees.

The PRESIDENT said scarlet fever was now of so mild a type that it seemed unnecessary, and a waste of public funds, to treat it in hospital. But 30 years ago it was a much more serious disease. Measles had become more dangerous, and diphtheria was increasing. Cancer at the present time was largely on the increase, and many cases came for treatment to London from outside the metropolitan area. Many of the infirmaries had no cases of advanced cancer, and some cases did not remain in those institutions for more than a couple of months. Advanced inoperable cases could not be looked after at home, as they upset the household too much, and a large proportion of them could not at present come into hospitals or other public institutions.

Reply.

Dr. BUCHAN said he did not regard small-pox as so terrifically infectious as some of the older authorities considered it to be. And if anyone proposed to treat it along with other diseases in a general hospital, he would not try to dissuade him from doing so. Whatever people might say as to the number of Poor-law beds available, his view was that there were not yet sufficient beds in this country available for public health work.

ABERDEEN MEDICO-CHIRURGICAL SOCIETY.

A MEETING of this Society was held on Oct. 28th, when Dr. J. M. CROMBIE delivered a presidential address on the

Treatment of Fractures of the Mandible.

The commonest causes of these fracture, he said, are motor-cycle accidents, blows of the fist, kicks from horses, and industrial accidents. Generally the fracture is compound into the mouth; the site may be almost anywhere, but it is most often in the bicuspid or canine region. Very often a fracture there is accompanied by a fracture of the angle or ascending ramus on the opposite side. Oblique fractures are the rule, although transverse fractures are met with occasionally at the symphysis. In addition to the usual symptoms of fracture there are several special features in fracture of the mandible—viz., a little hæmorrhage into the mouth, inability to close the mouth and to articulate properly, and dribbling of saliva. The fragments can be seen to move when the patient swallows and there is usually a definite irregularity in the line of the teeth. In single fractures the smaller fragment usually over-rides the larger; in double fractures the centre fragment usually drops downward. Dislocated teeth are very common and care should be taken that a tooth has not dropped between the fragments. Fractures of the ascending ramus are usually accompanied by much swelling but very little displacement. Crepitus, difficulty in moving the jaw, and deviation to the affected side are the symptoms of fracture of the neck of the condyle.

Before treatment is begun, said Dr. Crombie, a good X ray photograph must be taken—especially an oblique view. A preliminary cleansing of the mouth is also necessary, as well as a dose of antitetanic serum. In the region of the ascending ramus and angle very little in the way of treatment is required except the support of a bandage. Where there is displacement of the fragments of the mandible and splinting is to be carried out, impressions of upper and lower jaws must be taken in modelling composition. Impressions of these are cast in plaster-of-Paris and if the fracture is in the dentigerous area the lower model is sawn through the side of the fracture and articulated with the upper model so that the condition of the jaws is as it was before the fracture occurred. Many kinds of splint have been devised for fixation, but most of them are modifications of the classical Hammond or Gunning splints. The original Hammond splint consisted of a piece of wire which was fitted round the inside and outside of the necks of the teeth in the lower jaw; after reduction of the fracture into this splint fixation was obtained by figure-of-eight wiring round the teeth. This was made of iron wire which in practice was too soft and had a nasty taste, and also stained the teeth. More recently gold, dental alloy, or German silver-gilt have been used. In a modification of this splint, which he has devised, said Dr. Crombie, bands are fitted round the necks of the second bicuspids or other suitable teeth and a band fitting the inside and outside of the intervening teeth is soldered to these. The original Gunning splint was made of vulcanite and covered both upper and lower teeth and part of the gum with a hole in front for speech and one at each side to allow the saliva from the parotids to enter the mouth. For cleansing purposes it was drilled all over with small holes. The fragments were reduced into the splint and the jaw held up by a four-tailed bandage. The modern splint is made of metal and only covers the teeth, the upper and lower cups being soldered together if the mouth is to be kept shut; if the mouth is to be kept open they are joined by soldered struts. This splint is usually cemented on to the teeth and an aluminium chin support is used for a day or two.

Dr. Crombie believed that fractures in the dentigerous area of the mandible should be treated by a single Gunning splint, cemented on. With this treatment, he said, the temporo-maxillary joint does not stiffen and after a few days ordinary food can be taken. It is possible to use this splint only when there are teeth on each side of the fracture; otherwise a double Gunning has to be used. Shaky teeth should be left as they often heal in place and if they do not they can easily be removed later. Where there is a comminuted fracture with much sepsis, a Payne's cradle splint is to be recommended; this is almost a double Hammond, the upper and lower splints being held together by cross struts. Free drainage is thus obtained and the mouth can be washed out easily with an antiseptic solution. Discussing the treatment of cases where there is much bone loss, Dr. Crombie said that it is of the greatest importance to keep the fragments in their proper relationship to the upper jaw. In edentulous people he recommended wiring or fixation of the bony fragments by kangaroo tendon. In conclusion, he stated that no matter how a fracture of the mandible is being treated, absolute cleanliness of the mouth is essential. The mouth should be syringed with an antiseptic (mixture of equal parts of carbolic acid and liquor potassæ: one volume of mixture diluted with 39 volumes of water) before and after each meal, and if the splint is detachable it should be removed and boiled. The food must be soft, but with the aid of a mortar and pestle a varied menu can be given.

Lesions of the Hip-joint.

A further meeting of this Society was held on Nov. 4th, when Dr. JAMES CROMBIE took the chair, and Mr. ALEXANDER MITCHELL gave a demonstration of lantern slides illustrating diseases of the hip-joint. Dealing with tuberculous lesions of this joint, Mr. Mitchell laid emphasis on the persistent tendency of the head of the femur to become dislocated—a condition which if left untreated led to shortening of the leg, even up to four inches. Fixation of the limb in a fully abducted position with extension prevented the head slipping out in this way, and combined with treatment along modern lines would lead to cure of the disease, probably with impaired movement, but with little shortening or subsequent disability. Unless this was thoroughly understood, said Mr. Mitchell, even the most faithfully carried out treatment would not produce the desired result. Difficulties such as proper fixation and nursing could be overcome to a great extent by prolonged institutional treatment and careful observation afterwards. In conclusion, Mr. Mitchell put forward a plea for the more active treatment of fractures of the neck of the femur in the aged.

A discussion followed.

Reviews and Notices of Books.

THE FUNDAMENTALS OF SCHOOL HEALTH.

By JAMES KERR, M.A., M.D., D.P.H. Cantab., Consulting Medical Officer to the L.C.C. London: George Allen and Unwin. 1926. Pp. 859. 35*s*.

THE author of this treatise has had unrivalled qualifications for his task. He has specialised both in ophthalmic and in aural surgery, and his experience in clinical and administrative capacities has been such as to earn him the sobriquet "the Father of School Hygiene." If anyone were not aware of these facts he would be able to deduce them by applying the canons of higher criticism to this text-book.

The book begins with an exposition of modern views of heredity; then follow chapters on growth, physique, and nutrition—veritable store-houses of facts and figures interspersed with practical comments. There is also an account of the various formulæ which have been devised to estimate nutrition and physique, and the recent methods by which Martin Flack and others have sought to test physical efficiency. A description of vitamins and their relation to other food factors is included; in conjunction with this should be read the chapter on Light as a Healer, which deals particularly with the influence of ultra-violet rays, and the résumé of our knowledge of rickets and dental caries.

Sleep is discussed from the practical aspect; the treatment of enuresis is not so full as the difficult problem deserves. The chapters on the Spine and the Foot are of much general interest; the former contains a note on orthostatic albuminuria, here called lordotic. Tuberculosis, rheumatism, and heart conditions are considered in detail, the indications for prophylaxis and general care being given. According to Dr. Kerr, actual phthisis in children of school ages is a rarity, amounting to no more than 4 per 1000, but there are large numbers of children showing pulmonary gland infection, which is extremely amenable to treatment by ordinary hygienic methods. In this way he reconciles many apparently conflicting estimates of the number of tuberculous children. A sound explanation is given of what is here meant by hygienic treatment; and the school aspect is dealt with under the heading of open-air schools, which, as Dr. Kerr emphasises, must be far more than mere schools in the open. An attempt is made to describe mental development and intelligence from the physiological standpoint; some of the functions assigned to the supragranular layer of the cortex and to special areas of the brain can hardly be regarded as established. The presence of a localised moral centre is certainly not generally accepted; and, indeed, the whole question of the moral imbecile is in some confusion. Dr. Kerr is an enthusiastic advocate for the sterilisation of the mentally defective.

The later part of the work deals with medical inspection, administration, and infectious diseases; here a valuable citation of some legal points is followed by an account of the hygiene of school buildings, including notes on the official requirements. A section on the health of teachers, the criteria of their acceptance into the service, and the procedure and circumstances of sick leave and invalidity is welcome. Lastly, there is a concise explanation of the use and methods of statistics. No bibliography is supplied, but references are given in the course of the text.

The volume is packed with information, and will be valued by everyone who is concerned with the health of children. And what practitioner is not?

THE SURGICAL TREATMENT OF GOITRE.

By WILLARD BARTLETT, M.D. St. Louis. London: Henry Kimpton. 1926. Pp. 365. 37*s*. 6*d*.

THIS is probably the largest volume yet published in England or America that is wholly devoted to the surgery of the thyroid gland. Every aspect of the subject is dealt with exhaustively and the text is throughout based on the author's extensive personal experience. It is not a book that will fill the occasional thyroid operator with confidence, for a careful reading of it will certainly impress upon him the many difficulties that are sure to be encountered, but he will obtain from it much sound advice which will probably save him from some of the pitfalls. The book will be read with interest by the experienced operator who will note the many idiosyncracies of Dr. Bartlett's technique, perhaps with profit to his own. Of particular value, perhaps, is the chapter on anæsthetics; the author favours a combination of local with light general anæsthesia. Twenty-three pages are devoted to the subject of ligation of arteries, Dr. Bartlett having found the iodine medication of Plummer to be less efficient than it appears to have been at the Mayo Clinic. In this he is at variance with many other operators. The book is fully illustrated.

The Thyroid Gland. By CHARLES H. MAYO, M.D., and HENRY W. PLUMMER, M.D. The Beaumont Foundation Lectures. Same publishers. 1926. Pp. 83. 8*s*. 6*d*.

A SUBJECT so debatable as the diseases of the thyroid gland and their treatment is productive of an increasing flow of literature. For those who are too busy along other lines to keep pace with the output a concise summary of our knowledge is of value. The position in 1925 is well summarised in this slim volume, where each author is responsible for about half, and each has made his portion of great interest. Dr. Mayo has contented himself with giving an account chiefly of the work and conclusions of others concerning the history, anatomy, physiology, and chemistry of the thyroid, with the ætiology, bacteriology, geography, and metabolic influence of goitre. Thus he describes the work of Rosenow upon the bacteriology of goitre, with his claim to have reproduced diseases of the thyroid in animals, but makes no comment on the validity of these claims or their application in treatment.

Dr. Plummer's contribution, on the other hand, expresses chiefly his personal views, and he leaves the reader in no doubt as to their nature. He deals in an interesting way with the classification of goitre and the clinical aspects of hyperthyroid states. He then discusses the theory of thyroid dysfunction, and this section, which summarises his experience with the use of iodine, is the most valuable part of the whole book. It was in March, 1922, that he first began the administration of Lugol's solution which has had so profound an effect upon the therapeutic and surgical treatment of hyperthyroidism. Control of the disease has been so satisfactory that Dr. Plummer finds that preliminary ligature of the thyroid arteries has been almost abandoned. Operative mortality has been very greatly reduced and post-operative control can also be maintained. He makes some startling statements concerning the treatment of colloid goitres with desiccated thyroid. The possibilities of thyroid medication will be fully impressed on anyone who reads Dr. Plummer's stimulating pages.

INTRACRANIAL LESIONS.

Studies in Intracranial Physiology and Surgery. By HARVEY CUSHING, M.D. The Edinburgh Cameron Prize Lectures. London: Humphrey Milford, Oxford University Press. 1926. Pp. xxii. + 146. 8*s*. 6*d*.

EVEN to-day the belief is too widely held that the physiology and pathology of the brain is but little understood and that the treatment of intracranial lesions holds out but small hopes of success. Dr. Harvey Cushing has already done more perhaps than any other living worker to dispel this belief, and these lectures will bring conviction to any sceptics who read them carefully. A wealth of information is

here gathered in a small space, and is presented in an easy narrative style. The story is not confused by a mass of pathological and scientific detail. We regret only that this course of lectures was not expanded to include an account of the author's work upon the meningiomas and the tumours of the nervus acusticus.

The first lecture is devoted to a consideration of the cerebro-spinal fluid and its circulation. Step by step the growth of our knowledge in the method of the secretion and absorption of the fluid is traced in an account which becomes the more interesting in that Dr. Cushing shows how his own knowledge was obtained and his own difficulties overcome. It is in the development of this line of work that he and his colleagues have specially excelled; but although he describes fully his own chemical and experimental investigations, full credit is given to other workers. The ingenious experiments of W. E. Dandy in producing hydrocephalus; the work of L. H. Weed in determining the method of absorption of the fluid and of altering the amount of fluid by the intravenous injection of hyper- and hypotonic solutions; the observations of Harvey upon the functions of the meningocytes to form a new limiting membrane, to keep the fluid paths free of blood and inflammatory products, and their importance in the formation of the meningiomas—all these are described in detail. In the second lecture, which is devoted to the pituitary gland, a few historical notes are followed by a detailed description of the histology and functions of the individual portions of the gland. Of especial interest is the account of the importance of the pituitary in the production of glycosuria and polyuria. The latter part of the lecture is devoted to surgical considerations, and a warning is given that at present it is premature to believe that the internal secretions of the gland can be controlled by surgical procedures. The last lecture, which is entitled Intracranial Tumours and the Surgeon, describes shortly the enormous progress that has recently been made in the diagnosis and treatment of intracranial tumours, and it is shown that the diagnosis of the presence of the tumour, of its site, and of its nature, has reached a stage that a few years ago would have been regarded as impossible. Dr. Cushing lays great stress upon the fact that the prognosis largely depends upon the pathological nature of the tumour, and he gives an account of his work with Dr. P. Bailey in classifying the gliomata and other neoplasms. At first sight this classification appears to be very complicated, but it is shown so clearly that the clinical progress depends on the variety of tumour that a knowledge of these types becomes essential.

The work is one of great interest and should not only be read by those who are interested in cranial surgery, but by all practitioners, for it demonstrates how much may be expected from the introduction of modern surgery into the treatment of these difficult cases.

THE INNERVATION OF THE URINARY BLADDER.

Die Innervation der Harnblase; Physiologie und Klinik. By Dr. HELMUT DENNIG, Privatdozent for Internal Medicine, Heidelberg. Berlin: Julius Springer. 1926. With 13 illustrations. Pp. 98. M.6.90.

DISSATISFIED with the usual descriptions of the innervation of the urinary bladder, and aware of the discrepancies and contradictions in these, Dr. Dennig has undertaken afresh an investigation of the problem, which he has approached from anatomical, physiological, and clinical sides. A full account is given of the results of section of the various nerve supplies (nervi pelvici, hypogastri, and pudendi), and of the clinical symptoms and signs in bladder disorders of spinal origin. The sensibility of the bladder receives careful consideration. There are chapters on the central (cerebral) representation of bladder mechanisms, on functional bladder impairment, on pharmacological investigation, and on diagnosis and treatment. More than nine pages of references are appended. It is difficult to give even a precis of the author's findings, in view of their detailed character and their wide range (from anatomical minutiæ to the "symbolic pollution" of the psycho-analyst). But we have found the book peculiarly interesting and informative, and commend it to the neurologist and clinician because of its scientific tone and its cautious conclusions. It would be assured of further appreciation were it to appear in an English edition.

CAVERNOUS SINUS THROMBOPHLEBITIS,

And Allied Septic and Traumatic Lesions of the Basal Venous Sinuses. By WELLS P. EAGLETON, M.D., Medical Director, Newark Eye and Ear Infirmary, Newark, N.J., &c. New York: The Macmillan Company. 1926. Pp. 196.

Dr. Eagleton has written a record of personal experience in the diagnosis and treatment of the always somewhat serious affections of the venous sinuses of the brain, in particular of the cavernous sinus. His method is to illustrate the ætiology, clinical varieties, and complications by specific clinical cases in greater or less detail, and on these to pass some critical comment. Numerous references are given to the literature at the end of each chapter or section. A presentment of this kind has both advantages and disadvantages; if the reader goes carefully through the clinical records his patience will be rewarded; yet he may at the same time get the impression that the synthetic study of the author's abundant material leaves a little to be desired. We miss really adequate anatomical diagrams or drawings of the structures with which he is dealing, for those on p. 111 are curiously incomplete; the clinical and pathological photographs are good. The chapter on differential diagnosis is unexpectedly meagre, whereas those devoted to treatment are more satisfying.

JOURNALS.

QUARTERLY JOURNAL OF MEDICINE.—The October number contains the following articles. Studies in Calcium and Phosphorus Metabolism. Part IV. The Influence of Free Fatty Acids in the Intestine on the Absorption and Excretion of the Mineral Elements, by S. V. Telfer. Previous papers have been published by the author in this journal on Calcium and Phosphorus Metabolism (*Quart. Jour. Med.*, 1922–23, xvi., 45, and 1923–24, xvii., 245) and the series is here continued. A child suffering from catarrhal jaundice formed the subject of the investigation and a study of mineral metabolism was made at three periods of the illness showing widely different levels of fatty acid concentration in the intestine, owing to alteration in the elimination of bile. Phosphorus absorption was greatest in the first period of the illness, when bile was absent from the intestine and a large excess of fatty derivatives were present. The relationship between this and the calcium combinations in the gut are also discussed.—Studies in Calcium and Phosphorus Metabolism. Part V. Infantile Rickets: the Excretion and Absorption of the Mineral Elements and the Influence of Fats in the Diet on Mineral Absorption, by S. V. Telfer. Further researches are detailed on the excretion of mineral elements in infantile rickets. Early cases were investigated, the minerals in the urine and fæces and the composition of the fæcal solids being determined. The results are compared with similar data previously obtained in normal subjects. During the active stage of rickets there is an excessive loss of mineral salts in the fæces, during healing there is an increased absorption from the intestines. The influence of fat in the diet was also determined, and it was noted that in accordance with their therapeutic values fish-liver oils increase the mineral retention values in rickets, whereas olive oil

and butter had no such effect. It is suggested that cod-liver oil produces its action in rickets by allowing free absorption of the mineral elements from the gastro-intestinal tract.—The Effect of Exercise on the Pulmonary Ventilation and Rate and Depth of Breathing in Chronic Bronchitis. Paper I. By J. M. H. Campbell and E. P. Poulton. A series of patients suffering from chronic bronchitis of varying grades of severity were housed for the night and the greater part of the day in a chamber containing 40 per cent. of oxygen for a period of a week. Observations were made on the respiratory exchange before, during, and after this period. The effect of exercise upon the ventilation and respiratory exchange was especially investigated. In this paper the pulmonary ventilation of patients with chronic bronchitis, not undergoing oxygen treatment, is considered before and after exercise. It was found that the ventilation at rest is just above normal, whereas the alveolar ventilation is about the same as in health. Exercise increases the rate of respiration, but the alveolar ventilation is relatively low. The fact that normally an increase of CO_2 increases the respiratory depth, and a deficiency of O_2 increases the respiratory rate was confirmed.—The Effect of Exercise on the Respiratory Exchange in Chronic Bronchitis. Paper II. By J. M. H. Campbell and E. P. Poulton. The changes in oxygen intake and carbon dioxide output as the result of exercise in cases of chronic bronchitis are now described. More oxygen was used during work and the percentage of carbon dioxide in the expired air was invariably lower in chronic bronchitis than in health. This appears to be the essential factor of the breathlessness. In myocardial disease the gaseous exchange may be very poor in spite of deep breathing. The effect of residence in the oxygen chamber will be described in a third paper.—The Action of Insulin in Glycogen Formation and its Therapeutic Application, by R. D. Lawrence. Although it is recognised that insulin is a necessary factor in carbohydrate metabolism, producing on injection a condition of hypoglycæmia, the mode of action is in doubt. Here it is definitely stated as proven that insulin forms glycogen and that this is its main, if not its sole, action. Insulin is therefore anabolic, preparing and storing carbohydrate for combustion, although not actually burning it. The effect of exercise on a diabetic who is taking insulin is to burn up the carbohydrate, empty the glycogen stores, and thus produce hypoglycæmia. Insulin is also probably essential for the storage of glucose produced from protein, in the form of glycogen, and it may also check the formation of new sugar from protein. It is almost certain that fat is converted into glucose, and this is not changed into glycogen in the absence of insulin. It is possible that the production of ketones is a normal step in the conversion of fat into carbohydrate, which is, however, a gradual process. If the change is unduly accelerated in disease or starvation, by the deficiency of combustible carbohydrate, then the ketone bodies may be formed so rapidly as to produce clinical ketosis. It is also suggested that when glycogen is deficient the stimulus for the conversion of fat into carbohydrate is supplied by a hormone from the pituitary. The paper concludes with a consideration of the therapeutic aspect of the glycogenic theory of insulin action.—Some Observations on the Recorded Mortality from Diabetes in Recent Years in England and Wales as a Whole and its Principal Divisions, including London, with Special Reference to the Introduction of Insulin, by Matthew Young and W. T. Russell. By the middle of the year 1923 insulin was available in this country in sufficient quantities for the treatment of diabetes. An endeavour has been made to determine the effects of its use upon the mortality figures for diabetes and the age distribution of the disease. There is no accurate information available as to the number of diabetics in this country, but if the average duration of life is five years from the date of diagnosis of the disease, then there would be about 24,000 diabetics in England and Wales in the period 1923–24, and 29,000 for the British Isles, and of these 40 per cent. would be aged 65 and upwards. The figures show that previous to the introduction of insulin the mortality-rate for diabetes was definitely falling, owing probably to treatment by starvation. Since the introduction of insulin treatment the further fall in the death-rate has been relatively slight.

THE JOURNAL OF INDUSTRIAL HYGIENE for November is devoted entirely to various aspects of silicosis. In the opening paper E. L. Collis deals yet again with the statistical characteristics of dust-phthisis, but he reinforces old arguments by appeal to new and as yet unpublished data of occupational mortality for the years 1921–23. The data confirm in a signal way such earlier conclusions as that silicosis is only one of the dust diseases, of which bronchitis is the most important, that it occurs in association with Bright's disease, and that it possesses definite statistical characteristics which enable its presence to be detected, as, for example, among coal-miners, even when the phthisis mortality is below normal.—This latter point is taken up in the second article by N. Tattersall from the clinical side. He tells of the dust-risk for that small group of miners who sink and tunnel through sandstone rocks to reach the coal seams, and then describes the clinical features of 22 such miners who came under his observation as tuberculosis physician; he illustrates the silicosis found by six convincing radiographs. The condition is clearly identical with that seen in South African gold-mines, and is equally fatal. Dr. Tattersall instances six men who, three and a half years ago, were working together boring a hard heading, all of whom have since died of tuberculous silicosis.—Some relief to the deadly nature of silica dust is given by P. Heffernan, who tells of exposure to this dust without the occurrence of silicosis; he introduces his paper by interesting references to the ancients, whom he says did not suffer from stone-masons' disease, because they seldom used sandstones for building purposes. He then tells of certain brick-makers in Derbyshire who make silica bricks, but, although the process is a dusty one, do not suffer therefrom. The dust in this instance is composed of fine silica sand mixed with clay, which holds the bricks together (silica 83 per cent. and clay 9 per cent.). The only cases of silicosis seen among 176 regular brickmakers had worked previously as dressers of Derbyshire gritstone. Comparative radiographs are given of such a stone-dresser and a silica brickmaker, which show the lungs of the latter clear. Statistics are given showing a phthisis mortality per 1000 of 7·7 for Derbyshire gritstone masons and of 0·6 for the brickmakers. This immunity from silicosis when the silica dust is mixed with clay is comparable to that previously found in Stirlingshire and Yorkshire. The reason is yet unknown.—The next article, by E. H. Kettle, is a summary telling of his own experiments with silica. They show that silica is a definite tissue poison, and that when fine silica dust is introduced into the body it passes fairly rapidly into colloidal solution; in this form it attacks and kills the living tissues. Such necrotic foci provide a pabulum, especially favourable to the growth of tubercle bacilli, which, after injection, are found in far larger numbers in such silicotic tissues than in tissues damaged by other necrosing agents. Prof. Kettle holds that the silicotic lung favours the tubercle bacillus, not because it is fibrotic, but because it contains silica.—The series of articles is completed by a note by P. S. Hay describing shortly a dust-trap for catching dust generated by percussive rock-drills. Compressed air escaping from the drills is used, to act on the ejector principle for creating a localised exhaust draught. This draught sucks away the dust as it is formed and carries it into a filter formed of a flannel cylinder, which terminates in a metal box. The filtered air escapes from the flannel, while the dust drops into the box. The device should prove of value wherever percussive drills are used, either in mines or for dressing granite.

THE LANCET.

LONDON: SATURDAY, DECEMBER 4, 1926.

HYGIENE IN THE ELEMENTARY SCHOOL: PRECEPT AND PRACTICE.

IN his report[1] for 1925 to the Board of Education Sir GEORGE NEWMAN says that "it is common knowledge that a considerable number of schools throughout the country fail to reach a minimum standard of health and sanitation." He cites one county where there are 51 schools with no water-supply at all; 97 whose old and unhygienic desks require replacement; 62 in which the playgrounds are unsuitable in size, position, or surface; and 35 with no other sanitary accommodation than privy middens. Reference to the reports of school medical officers will show that in many urban districts conditions are no better. One of these officers, for instance, writing of a county borough with a population of 91,000, makes the following statements:—

"the majority of the schools were erected prior to 1880 . . . certain school buildings are out of repair, the roof gutters and exterior walls being defective and damp in places. . . . Many of the schools are provided with trough closets and it is quite common to find them in a foul condition. . . . At almost every school the urinals are not provided with flushing apparatus, and complaints have been received of the stench arising from these conveniences. The major portions of the playgrounds at several schools are unpaved—becoming pools of water and mud in wet weather."

These conditions are not exceptional; the criticisms apply to elementary schools all over the country. But to tell the truth in plain language is often impolitic when a medical officer is faced by a committee which has false standards of economy, is versed in procrastination, is ignorant or unheedful of sound hygiene, and glad to accept as sufficient the minimal requirements of the Board of Education. This country has little to be proud of in tolerating class-rooms which allow a floor space of only 10 square feet per child—less than is permitted by any other great nation. Everyone who cares for preventive medicine must agree with Dr. JAMES KERR, whose text-book we review on another page, that "it is time to give up the squalid ideals in relation to the elementary school-room." The moment may be wrong for the wholesale outlay of money on new buildings or on radical alterations of structure, but it is not wrong for the correction of definite nuisances and dangers to health, and measures to this end must take precedence of newer schemes, however picturesque and attractive. The whole position is disappointing. In his report for 1918 Sir WILLIAM HAMER said: "It may be assumed that a quarter of a million school-children in London are brought up in ignorance of, and without the possibility of, that minimum of attention to hygienic requirements which should now be necessary in every civilised community." The same holds good to-day, not only in London, but throughout the country, and the effects of school inspection and treatment are largely nullified by allowing inimical influences full play in the school-room.

[1] Report for 1925 of the Chief Medical Officer to the Board of Education. London: H.M. Stationery Office.

The teaching of elementary hygiene now has a place in the curriculum; but when the school conditions are such as have been described, the oral lesson is so much waste of time. NOEL PATON and LEONARD FINDLAY have recently shown that the greatest single factor in healthy childhood is efficiency of the mother. Legislation has delivered the future parents of the race into the hands of the State at an impressionable age, and though satisfactory education of their intellect may be impossible in our elementary schools for many years to come, the education of their bodies is practical politics—an ideal infinitely easier to realise. And personal health, often made possible by higher wages and easier conditions, will go far to promote the maternal efficiency which ought to give children of the next generation a better start. Such a start is profoundly important, but even though we cannot secure ideal homes for the children of to-day, we can at small cost ensure tolerably healthy school conditions and there instil, by example more than precept, the knowledge of much that is essential to health and happiness. From the psychological point of view good surroundings are as necessary as suitable and sufficient food, fresh air and sunlight, exercise and rest, and a child once accustomed to conditions that are bright, airy, clean, and wholesome will grow intolerant of what is mean, dirty, and squalid. In hundreds of schools, however, it is the mean, the dirty, and the squalid that are put before the children's eyes. Overcrowding leads to a loss of self-respect, prevents the development of individuality, encourages filth, vermin, and infectious or contagious diseases, and renders ventilation more difficult. Many schools are dirty. Little imagination and less science are shown in the dusting, brushing, and scrubbing that go on fitfully; the surroundings and the playground (if any) are often nothing more than patches of mud, much of which the children bring into school on their boots. The walls of rooms are made of bare brick, or have dull, rough surfaces; the rooms themselves are filled with old, unnecessary, dusty furniture, and decorated with uninspiring pictures. Even to-day there are practical exponents of the hot-air system of heating and ventilation; even to-day the draught and open window are unintelligently handled, lights are ill-placed, and windows grimy.

The present drop in the school population gives an excellent opportunity for closing structurally unsuitable schools and for bringing down the numbers of children in class-rooms. These measures would be a big step in the right direction. Improved cleanliness can be secured by supervising the work of caretakers and cleaners, and by removing useless furniture or impedimenta; walls should be made smooth and painted in flat colours—bright, but not glaring—so as to be readily washed, whilst floors may be treated with dust-allaying oil. The formation of smaller classes lessens the difficulty of ventilation; the children respond better to discipline, and desks can be spaced to meet the need for light and air. Heating and ventilation in schools admittedly present difficult problems, requiring much careful thought, but there are few systems in existence—however inefficient in themselves—that could not be better, and probably more economically, run if a little more intelligent supervision were given to them. To hold open-air classes does not necessarily require much ingenuity or special provision; the shed in the playground may give ample protection even in cold weather, and simple exercises at intervals not only keep up the necessary heat, but bring about adequate adaptation in the

whole mechanism of the child. Perhaps the gravest leakage of heat occurs through sodden footwear, which many children have to wear throughout the day during wet weather. As a source of debility this is probably of great importance, yet the provision of simple slippers—which can be made by senior girls at little expense and with some educational benefit—is the exception in most school areas. The midday hour, especially in country districts, may well be utilised in giving the children a hot meal. It is sometimes possible to use the opportunity for teaching plain cookery and dietetic principles to the bigger girls, and if efficiently supervised, a meal can be made into an occasion for imparting cleanly and orderly table habits. Again, the play instinct of children largely determines their growth, so that the lack or unsuitability of playground accommodation cries out for immediate reform. Washing arrangements —for the most part inadequate—now exist in most schools, but often the water will be found to be turned off, "as the children make such a mess." One, or perhaps two, roller towels are used for the removal of dirt both from sweating or perhaps hastily soused hands and faces, and from boots. There is no need to refer to septic conditions of the skin, nose, mouth, ears, and eyes. It is not enough to have wash basins; there must be soap, preferably in receptacles from which only a small quantity can be taken at one time. Paper towels are satisfactory and not expensive, in view of their advantages. Some responsible person should always be present during the times of ablution. Erection of spray or shower baths may be somewhat expensive, but in the long run it is cheaper than the present involved system of compulsory cleansing, and the moral value is beyond calculation. Swimming baths are a luxury, excellent as they are. As for the condition of sanitary conveniences, that is something that must be faced before any pretence is made to inculcate the principles of hygiene. Till these abuses are dealt with there is little need to consider the broader aspects of structural alteration, building sites, exposure, and surroundings; but enough has been said to show the immediate necessity for public bodies, educationists, and medical men to make further efforts to improve the conditions of elementary schools.

EXPERIMENTS ON ANIMALS.

A CHARGE of alleged dog-stealing led recently to the conviction of a dealer who has supplied animals to the University College School of Physiology; the episode has been followed by prompt inquiry on the part of the authorities, by whom an official statement has now been issued. The episode has raised questions concerning the most satisfactory method of securing an adequate supply of animals for the purpose of research. Presumably it would not be impossible for the Medical Research Council to undertake the breeding of those required, though there is potential material already in existence. In a letter to the *Times* Prof. A. V. HILL has pointed out that over 50,000 stray, homeless, and unwanted dogs are annually sent to the lethal chamber, and the diversion of some of these to the service of scientific research would solve the problem simply and sensibly. But though this solution of the difficulty is adopted in America and elsewhere, in England it is barred by the law. In 1906 Parliament passed a Dogs Act, concerned with divers matters such as the liability of dog-owners for injury to cattle, the compulsory dog-collar, and the exemption of sheep-dogs from licence duty. One section of this measure dealt with the seizure and detention of stray dogs and their destruction by the police, if unclaimed, after a proper interval and after due notification to the owner, a register being kept with a brief description of every dog thus seized and detained. The humanitarian zeal shown by some propagandists, and the distrust of medicine shown by others, procured the insertion of a sub-section (Section 3, Subsection 5) enacting that "no dog so seized shall be given or sold for the purpose of vivisection." This clause, Prof. HILL suggests, should be repealed, but we fear that the attempt to do so would rally once more those who have supported the kindly but narrow views of the promoters of a series of Dogs' Protection Bills.

There are as many dog-lovers in the medical profession as in any other. We shall all agree that experiments upon dogs and cats should be restricted to the minimum. There would probably be scant professional opposition to a regulation that these animals should not be used for demonstrating to students accepted observations which need no further confirmation, but that is a very different thing from enacting by law that no canine subjects should be employed in any capacity for medical research. The reasons for using the dog for experiments devoted to the diminution of human and animal pain were fully and fairly stated in the memorandum[1] issued by the Medical Research Committee in 1919. It was there shown how such experiments had led to the prevention of disease and suffering in matters such as rickets, disorders of the teeth, the effects of alcohol and diseases of the heart, and how much the experiments had contributed to our knowledge of blood circulation. It is probable that some who are ready to take a prominent part in what they consider to be a defence of the dog have never studied this document, which should be supplemented by Dr. C. H. BEST'S letter on p. 1192 in the matter of insulin research, while many who now assume that all experiments classed as vivisection necessarily involve disregard of pain do not read the Inspector's reports prefixed to the annual Home Office return under the Act of 1876. That Act makes animal experiments legal, subject to an elaborate system of licensing, regulation, and inspection. Inspecting officers pay frequent visits, usually without previous notice, to all places registered for experiment. In the latest report, that for 1925, the inspectors found all animals suitably lodged and well cared for, and the licensees generally attentive to the requirements of the Act and the conditions attached by the Home Office to their licences. They report only two cases of irregularity in the year. One of these was the unlicensed immersion of trout in polluted water under a misunderstanding of the scope of the Act; immediate steps were taken by the offender to obtain a licence and the appropriate certificate. The other irregularity concerned certain simple inoculations made in the case of cats; the inoculator held Certificate A but not Certificate E; it was clear that he had erred unwittingly, and it was considered sufficient to admonish him. The importance of the report is that it shows how large a proportion of experiments are painless, and how great is the care taken to prevent the suffering of pain.

However reassuring an Inspector's report may be, there will still be dog-lovers who look upon every research worker as a ghoul, while forgetting that veterinary medicine owes a debt to medical research. Mr. STEPHEN COLERIDGE inserts in a letter to the *Times* the observation that "it is, of course, idle to

[1] THE LANCET, 1919, i., 947.

expect from a man of science any consideration of pity for vivisected dogs "—it is idle to expect from Mr. COLERIDGE reflections of any other character. A discovery of modern science—the use of insulin in cases of diabetes—has been made by means of experiments upon dogs, and to make this discovery fit into the contention that vivisection is unjustified by results, Mr. COLERIDGE must deny that insulin is a successful remedy. He does so, and he adduces figures from the returns of the Registrar-General in support of his denial. Here, at any rate, is a definite issue of fact upon which medical science can meet him confidently. The reply by Prof. T. R. ELLIOTT and Sir WALTER FLETCHER, restating matters within the knowledge of every medical practitioner, deserves the widest possible publication. The records of hospital patients treated with insulin show the vast misery that has been saved by the discovery.

SMALL-POX IN THE NORTH.

SMALL-POX having failed in recent times to make itself felt as a fatal disease is now clogging the machinery of local government by its mere abundance. In the last Weekly Return there were 353 cases, all except 17 notified from counties north of the Dee and Humber, and 288 of them from the small county of Durham. Middlesbrough was the first scene of this northern outbreak; it was introduced there by a visitor in 1920, and up to the middle of 1925, when it rapidly diminished, about 1800 cases had been reported, all of conspicuously mild type. In the previous Middlesbrough epidemic of 1897–98 Dr. CHARLES DINGLE, medical officer of health, had to report[1] a third fewer cases, but attended with 166 deaths, and (in contrast with the Gloucester epidemic) the outbreak was only with difficulty got under control. In the recent epidemic Dr. DINGLE strove manfully to stem the tide, but receiving little or no support from his sanitary authority, he regarded it as hopeless to obtain immunity by vaccination, and accepted[2] the second-best plan of letting the population obtain immunity by contracting the disease in this mild form. Only an occasional case is now appearing in this town of 136,000 inhabitants.

The next serious outbreak was in Ashington, mid-Northumberland, where 500 cases occurred in two years in a colliery population of about 30,000. Here the sanitary authority, having no small-pox hospital, fell back on the isolation hospital, described[3] by Sir GEORGE NEWMAN as not at all suitable for the purpose. Friends and relations were permitted to visit patients at this hospital without proper precaution against the spread of infection, with the result that much inconvenience and loss of wages occurred locally, and infection spread to other areas. The part-time M.O.H. was not in a position to meet such a public health crisis in an intensely antivaccinist population, with a sanitary authority which strenuously opposed any efforts to get contacts vaccinated. Finally, notified cases seem to have been left at home with little or no supervision. The position at Ashington has since changed for the better with the appointment of a new medical officer, still a part-timer. The next outbreak occurred at Newburn, a colliery and iron-working district on the extreme western boundary of Newcastle, and gave an anxious time to the medical staff of that county borough. Here the outbreak was regarded, not as small-pox, but as a mild inoffensive disease, probably chicken-pox, and in the great majority of cases notified as small-pox no action of any kind was taken. Most of the cases of small-pox that occurred in Newcastle were traced directly to infection from Newburn; but each of the numerous outbreaks in the city remained restricted to one or two cases at most, showing how readily the disease is controlled when handled efficiently. During the past summer the disease crossed the Tyne, and outbreaks began to appear in the county of Durham, where the C.M.O. took a very active part in assisting and advising the district medical officers. Unlike Northumberland, Durham is a very densely populated county, and the result of mismanagement would be seen in thousands rather than hundreds of cases. Three members of Dr. EUSTACE HILL'S health committee, who criticised his drastic action at one meeting, were absent from the next, being themselves confined to hospital with small-pox. It is noteworthy that in none of the towns on Tyneside has the disease got any real hold, because it has been grappled with from the start.

In Gateshead a considerable number of cases were discovered by the M.O.H. in a very thorough house-to-house investigation of some streets from which one or two cases had been reported. In Newcastle, where the cases have never exceeded an occasional one, two, or three a week, the population is relatively well vaccinated, this measure having been pushed quietly and unostentatiously during the past year or two. Infantile vaccination in Newcastle approaches 70 per cent. But Newcastle has stood by its neighbours, and at the present moment is housing 30 or 40 cases from the Brandon district of Durham, where existing accommodation is overtaxed, and cases have been sent to Sealburn, Blacksell, and Shincliff, and even to Middlesbrough, while the suitability of Brancepeth Castle as a temporary hospital is being canvassed. In spite of all this costly inconvenience the vaccination centres are only sparsely visited. Contrast with this the extraordinary freedom of London from small-pox. At a recent meeting of the County Council, Mr. G. H. WALMSLEY, chairman of the Public Health Committee, said that during the years 1923-25 there had been 25 cases of small-pox reported in London, as compared with 11,630 in the rest of England and Wales. This he justly ascribed to the energetic action of public authorities in London in following up and vaccinating contacts, combined with the facilities for prompt diagnosis provided by the Council, and the close coöperation between all the medical officers concerned.

[3] Annual Report of C.M.O. of Ministry of Health for 1925, p. 36.

IT is a hundred years since the death of the illustrious Laënnec, and it is also exactly a hundred years since the second edition of his masterly work, the "Traité d'auscultation," was published. The Paris Academy of Medicine has taken the initiative in celebrating this double anniversary by a series of meetings on Dec. 13th, 14th, and 15th. On Monday, Dec. 13th, there will be an afternoon reception at the Académie de Médecine and the Hôtel de Ville, followed by a reception at the Sorbonne in the presence of the President of the Republic, at which addresses will be given by the Rector, Prof. P. Ménétrier and by Prof. A. d'Arsonval, Prof. H. Roger, and Prof. Léon Bernard. The foreign delegates will also speak. On the following day there will be a morning visit to the Musée Carnavalet and in the afternoon Prof. P. J. Bar, Prof. G. C. Mirallie, Prof. M. Letulle, Prof. E. Sergent and Prof. C. Achard will deliver addresses at the Academy of Medicine on different aspects of Laënnec's work. There will also be an exhibition of souvenirs. For Wednesday, Dec. 15th, the arrangements include a reception at the Hôpital Laënnec and an address by Dr. Rist, followed by visits to the Hôpital Necker and the Hôpital de la Charité. In the afternoon, during a visit to the Institut Pasteur, there will be an address by Prof. A. Calmette on Prevention of Tuberculosis since the Days of Laënnec. The fêtes will close with a banquet the same evening at the Palais d'Orsay. All who wish to join in these interesting ceremonies should communicate with the Secretary-General, Prof. A. Roussy, 21, Rue de l'École de Médecine, Paris, 6. We understand that the Royal College of Physicians will be represented by Sir John Broadbent and the Royal Society of Medicine by Sir StClair Thomson.

Annotations.

"Ne quid nimis."

THE RECOGNITION OF THE FAILING HEART.

THE word "cure" is hardly applicable to heart disease. We can relieve symptoms and improve the functional efficiency of the diseased organ, and we can look forward to the day when we shall be able to prevent heart disease, but a heart once damaged is permanently damaged, and can never be restored to its normal condition. The importance of early diagnosis is paramount, in order that we may be in a position to arrest the progress of disease before it is too late, and while the heart is still capable of meeting the demands of a life of moderate activity. In his Morrison lectures[1] delivered before the Royal College of Physicians of Edinburgh, Dr. John Cowan discusses the evidence on which such early diagnosis must be based. In most forms of chronic disease disturbance of function can be recognised long before the appearance of objective signs resulting from structural changes in the diseased organ, and nowhere is this more true than in the case of the heart. Dr. Cowan rightly emphasises the fact that the earliest sign of impending heart failure is impairment of the tolerance for exercise. It is surprising that in framing a prognosis, the importance of making a careful study of the heart's functional capacity does not appear to be more generally recognised. Despite the teaching of the past quarter of a century and more, despite the overwhelming evidence to the contrary afforded by the examination of hundreds of healthy young men during the war, it still happens that people with perfectly normal hearts are told they are suffering from heart disease because of the discovery of a systolic murmur or of occasional intermissions in the radial pulse due to ventricular extrasystoles.

Broadly speaking, there are two methods of estimating the heart's functional capacity. The one is to ascertain by careful inquiry whether symptoms of distress are produced by a degree of exertion which previously was well tolerated. A progressive diminution in cardiac response, no matter how trivial it may appear to the patient, provided it cannot be accounted for by other causes, is always suggestive of the approach of myocardial insufficiency. Allowance must be made for advancing years, and it is not uncommon for a man who retains his mental vigour to be unwilling to recognise the natural impairment of his physical capacity. The common tendency is for patients to make light of, rather than to exaggerate, the severity of their symptoms, the result, perhaps, of an inherent optimism or of the insidious onset of the disability. In many cases the history alone suffices to clinch the diagnosis, but at times it is desirable to supplement it by physical tests, which must, of course, be appropriate to the physique and age of the patient. They should, so far as possible, conform to the type of muscular activity to which the patient is habituated, and for this purpose there is none more universally applicable than the ascent of a flight of stairs. Even such a simple movement as raising the body with one foot on a chair is less trustworthy, for it introduces the factor of balance and the use of less-trained muscles. It is not only the form of the test which is of importance in the assessment of the heart's physical capacity, but also the criteria adopted in assessing the result of the test. Attempts have been made to obtain a numerical expression of the heart's efficiency, and probably the one which has gained most general acceptance is the increase in heart rate following a standard exercise, compared with the resting rate two minutes after cessation of the exercise. This is a rough guide but in no way fulfils the requirements of a truly quantitative test. Reliance should be placed rather on the severity of symptoms such as breathlessness, precordial discomfort, or dizziness induced by the exercise.

Dr. Cowan calls attention to the ominous significance of progressive changes in the physical signs, such as gradually increasing cardiac enlargement, impure heart sounds which subsequently give place to definite murmurs, and the earliest appearance of traces of œdema in the ankles and congestion of the internal organs. Similarly, a progressive fall in systolic blood pressure is a sure sign of myocardial failure. The systolic arterial pressure is a measure of the heart's capacity to meet its liabilities, and should bear a quantitative relation to the diastolic pressure, but as the heart finds it more and more difficult to carry on, the systolic and diastolic values tend to approach one another. Additional evidence of myocardial failure is sometimes afforded by the electrocardiogram. For example, bundle branch block already has an established place in prognosis, but there are other changes of a similar nature associated with the onset of failure, the significance of which is not yet fully understood.

RADIOTHERAPY IN GERMANY.

RADIATION therapy has passed through phases and fashions inseparable from the development of a new and important therapeutic agent. The old empiricism gave place to a new dogmatism. To-day there is a general disposition to return to older methods, but with this difference, that we need never go back to slipshod ways, for radiotherapeutics have become enriched by a wealth of technical resources and a harvest of clinical and biological knowledge. Its future lies in the application of these principles to properly selected cases. Towards that end the labours of our German colleagues are contributing in generous measure. The favourable impression given by the first volume of a comprehensive work on radiotherapy published in three parts during the last two years is fully sustained by the second and third volumes, dealing with the clinical aspect, special technique, and results of radiation therapy.[1] Surgery is divided into technical and clinical sections. For the convenience of surgical specialists without special radiological training, the essentials of physics are first summarised in an elementary article (Baerwald). Technique and biology are dealt with in the same introductory fashion (Rapp). Holfelder follows with a more detailed chapter on special technique, which includes a description of his "field selector," and contains a number of practical hints based on his personal methods. The technical section is completed by Rapp, discussing radioactive bodies. Its inclusion involves some repetition, as the ground was more fully covered in Vol. I., but gives completeness to a volume which is intended for the surgeon as well as for the radiologist. The clinical section contains some 80 pages on Carcinoma and Sarcoma (Werner) and the remaining 340 pages deal with other surgical conditions. This proportion should be noted by those in whose minds radiotherapy connotes cancer treatment. Prof. Werner's article is conservative in tone, and appears to summarise the present trend of German opinion in relation to cancer treatment by X rays. He opposes the "cancer dose" theory of Seitz and Wintz, but does not entirely reject the theory of the "irritation dose." His views on choice of method and selection of cases are sound and helpful. As to results, he admits that radical cures are few and that results of radiation are far behind those of surgery. He makes a good point in insisting that we should, in a given case, decide at the outset whether a palliative or a radical result is to be aimed at, lest the possibility of a good palliative result be sacrificed, as it often is, through overtreatment. Heliotherapy in surgical tuberculosis receives due attention. The photographs on pages

[1] Lehrbuch der Strahlentherapie. Edited by Prof. Hans Meyer. Berlin: Urban and Schwarzenberg. Vol. II. (Surgery). 1925. With 284 illustrations. Pp. 702. Vol. III. (Medicine). 1926. With 172 illustrations. Pp. 884. Price per vol., M.45

302 and 321 showing results in extreme cases are good propaganda, but that on page 322 appears to carry this to undue lengths. It represents an emaciated boy grotesquely mutilated by amputation, and bears the title "Example of the surgical treatment formerly employed in surgical tuberculosis." Jüngling emphasises the value of X rays in tuberculosis of bones and joints. Small doses, exact technique, and wise selection of cases, combined with good clinical judgment, are necessary to success. Holfelder treats of a miscellany of other surgical conditions. Interesting chapters on Radiation in Ophthalmology and Rhinology together with a section on Surgical Diathermy, complete the volume. Vol. III. is devoted to medicine. In a vigorous article, Pordes (Vienna) gives expression to the spirit of revolt against the too rigid technicalities in which X ray therapy has become involved. He charges the technician and the physicist with making incursions into the realm of biology, and of simplifying the monstrous complexity of biological processes to the point where they can be crammed into the rigid confines of a mathematical formula or of a regular curve; the physician who uses radiological treatment as an elastic therapeutic agent is unjustly regarded as guilty almost of malpraxis. Meanwhile, the patient's claims recede into the background, and the bewildered physician decides ultimately to work according to the scheme of school "X" or institute "Y," or even merely to follow the instructions given away at the time of purchase with apparatus "Z"! Pordes then applies himself to reconsidering the observed facts, and writes in a stimulating and commonsense vein. Other articles of special interest include Blood Diseases (Holthusen), Mediastinal Tumours (Kienbock), Pituitary Tumours (Kupferle), Malignant Diseases of the Thyroid (Haenisch), to name only a few. The special section on Diseases of Children is useful. The article on Graves's Disease is in the nature of a compilation, a defect from which the work, as a whole, is singularly free. We infer from this article that the bulk of evidence strongly opposes the often-repeated statement that X ray treatment seriously hampers surgical removal of the thyroid gland. This risk appears to have been exaggerated. Nearly all the articles have good case reports; statistical information as regards results is, for the most part, lacking. The indices to the separate volumes are excellent, and with the "contents tables" make reference to any special subject easy. The bibliographies are exhaustive. This text-book as a whole is one of the best and most complete works on the subject we have yet seen, and the editor and his collaborators deserve the highest praise.

RECURRENT IRITIS.

OPHTHALMOLOGISTS now regard recurrent iritis as generally due to metastasis from a focal infection and its radical cure as dependent on the removal of the source of infection. Acting on this idea, Drs. E. E. Irons and E. V. L. Brown reported two series of 100 cases each in 1916 and 1923 in which careful studies of each patient were made to determine what kinds of infection were present. The sources of infection were removed so far as possible and the effect on the eyes noted. They have now presented a report to the American Medical Association summarising the first 50 cases from which they have been able to obtain reports with reference to recurrence.[1] In 43 of these 50 cases there was no recurrence of iritis after a period of observation of from three to 12 years. In the remaining seven recurrence had taken place. In the former (non-recurrent) group the ætiology, in more than half the cases, was ascribed either to the teeth or the tonsils and removal of the source was a comparatively simple matter. In the small recurrent group more than half were ascribed to either syphilis, gonorrhœa, or tubercle. This affords prima facie evidence in favour of the author's theory of causation being correct. In one dental case, for instance, in which there had been 12 previous attacks there was none for four years after the removal of the teeth, and in one tonsillar case in which there had been three previous attacks there had been no recurrence nine years after removal of the tonsils. It cannot, however, be claimed that treatment on these lines is always infallible or sufficient. In one case attributed to the tonsils in which there had been 21 previous attacks there was no recurrence for three years in spite of the tonsils having been left in, and in another similar case where there had been three previous attacks no recurrence for four years. As was remarked in the discussion the hygienic treatment which the patient receives has also its effect. Of other sources of infection Dr. W. Zentmayer emphasised the importance of the prostate and said that infection from this source is probably more often non-gonococcal than gonococcal. It should be added that in the case of gonorrhœa routine treatment of the prostate during the acute stage is apt to aggravate the ocular inflammation. Another source of focal infection was suggested by Dr. Lloyd Mills, of Los Angeles, in whose experience a large proportion of cases of chronic ocular inflammation are found associated with heavy intestinal infections of protozoa and flagellates of proved tissue-invasive capacity and nearly always with an accompanying chronic colitis. Effective treatment directed to the cure of this condition has, according to him, had most encouraging results. The day is past when all cases of iritis were said to be either syphilitic or "rheumatic," and though a more scientific diagnosis may not always be easy, we now know the direction in which to look for it.

AMPUTATIONS AND ARTIFICIAL LIMBS.

IN an annotation on the adjustment of artificial limbs in our issue of Nov. 20th we commented upon the need of closer coöperation between operating surgeons and limb-makers. In a letter from Mr. Muirhead Little, which we publish to-day, he draws attention to another aspect of the question of the supply of artificial limbs to hospital patients. It is no reproach to the operating surgeon to say that, unless by chance he has had orthopædic experience, he will not want to instruct in details the limb-maker, with whom he, in present circumstances, seldom comes into contact. How many surgeons, having performed amputations of the thigh and seen the flaps soundly united, have opportunities to consider whether movement of the hip-joint is free and unrestrained? Yet it very often happens that there is contracture limiting flexion and such contracture, if of more than a slight degree, is fatal to free and comfortable locomotion on an artificial limb. A patient in such a condition may be sent to a limb-maker to be fitted, and although the socket supplied may accurately fit the stump, he finds that he cannot use the limb. The limb-maker may or may not realise what is the matter, and if he does, he may hesitate, on his own initiative, to send the case back to the surgeon with an intimation which in effect would mean that the latter had not done his work completely. Fifteen years ago there was a measure of excuse for all this, for amputations were few, and seemed to be becoming fewer; but since the great increase of motor-car accidents their number has much increased, and the subject of prosthetics has become proportionately more important. The British limb-making firms are second to none in skill, and are animated by the desire to do the best for their customers; at present their work is apt to go uncriticised, but honest criticism is absolutely necessary to efficiency, let alone progress. There is now in existence a first-rate institution—The Surgical Supply Depôt, Kensington—where among other things excellent provisional peg-legs or pylons are made, of which more use might be made in hospital practice than is at present done. We feel that a similar institution for the supply of permanent artificial limbs might be established under surgical supervision, with the coöperation of all the

metropolitan general hospitals. Opportunities for meeting the demand for artificial limbs at such an establishment would be open to all limb-makers, while the prescription and the approval of the limbs supplied would be in the hands of surgeons with special experience, They would supervise the training of the amputees in the use of the appliances, and discuss with the manufacturers both the limb to be made and any subsequent modifications that seemed needful.

CYCLIC VOMITING.

THERE can be few questions on which current opinion is in so fluid a state as on the ætiology of recurrent paroxysmal attacks of vomiting. The so-called cyclic vomiting of children and the "pernicious" vomiting of pregnancy are both *associated* with ketosis, and a generation of students has learnt to describe them as "due to acidosis." Marfan even gave the name "acetonæmic" vomiting to the recurrent attacks in childhood. A further question followed naturally on this explanation: What is the cause of the acidosis? Some have answered this question by positing an inherent intolerance to fats, and treat the condition by prescribing a diet in which fat is rigidly restricted. That ketosis is the *cause* of these conditions is perhaps still to a certain extent the conventional view, but in recent years it has been freely questioned, and the number of those who are convinced of it is probably rather small. A few years ago the causal connexion between ketosis and the vomiting of pregnancy was challenged, and support was given to the existence of psychogenic factors in the ætiology. A number of pediatrists have expressed a similar scepticism about the causation of cyclic vomiting. Prof. J. L. Morse, of Harvard, has recently dismissed it as a popular fallacy, and it has been the experience of many who are engaged in the treatment of children that the attacks of vomiting are generally associated with some dietetic defect—not by any means always an excess of fat—and respond to the correction of the defect, whatever it may be, without any particular restriction of the fat in the diet. Other cases occur in which the toxic element is small, and which present no fundamental distinction from the clinical picture of migraine. Doubt as to the adequacy of the ketosis theory opened the way for rival suggestions, of which there have been many. Chronic appendicitis has been put forward, particularly in America, as a common cause, and success has been claimed for the results of appendicectomy. Prof. L. T. LeWald, of New York,[1] has investigated a large number of these children radiologically, and gives the results of an analysis of 44 cases. He found some abnormality in a part of the intestinal tract in the majority of cases, but considered that no one condition was so constantly present as to suggest a true cause. Abnormal length of the colon was his most frequent finding, being present in 35 cases, while "dilated ptosed stomach" was found in 23 cases. The two conditions were often present together. Of the individual cases which he describes, one, associated with headache and strabismus and cured by operative correction of the latter, may well be classed as migraine. Another case, with redundant colon, obtained no relief from appendicectomy but was subsequently improved by a suitable abdominal belt. A third, previously attributed to acidosis, was found to have a severe degree of pylorospasm. Prof. LeWald concludes that cyclic vomiting is probably of reflex nature and is usualy associated with abnormalities of some portion of the digestive tract. The questions of whether these abnormalities are mainly congenital or acquired, and to what extent they are responsible for the symptoms, are not discussed, but raise some points of interest. His other conclusion, that "cyclic vomiting is not an entity, and has no specific cause" is perhaps the most accurate representation of the ætiology which can be given, and is one which will discourage the adoption of any stereotyped line of treatment.

[1] Radiology, November, 1926.

THE BRITISH SOCIAL HYGIENE COUNCIL.

IT will be remembered that a short time ago the National Council for Combating Venereal Disease changed its name to the British Social Hygiene Council and widened the scope of its work. There was a certain amount of opposition to a change of policy involving coöperation with local authorities in general health propaganda, but the report for the year 1925–26, which has just been issued, shows that fears of the direct work of the Council against venereal disease being reduced have not been justified by the event. Owing to pressure of work Sir Auckland Geddes has resigned from the presidency of the Council; Lord Willingdon has been elected in his place, which is especially appropriate, as the Council is shortly sending a delegation to India. The members of this delegation will be Dr. David Lees, of Edinburgh, Mrs. Neville Rolfe, secretary-general of the Council, and a secretary; expenses are being met by a voluntary fund raised in India, and invitations have been received from the governments of the chief provinces. The Council's work abroad, especially in the Dominions and Colonies, is well recognised, as was shown by the interest aroused by the Imperial Social Hygiene Congress held at Wembley last year, whilst its work at home continues to be of great importance. In particular the new programme of education demands notice. In presenting the principles of social hygiene to the public it became obvious that a definite statement on sexual continence was necessary. A committee consulted various authorities, and in March last the Council published the following:—

"The British Social Hygiene Council are of the opinion that: (1) In the interests of the race and of the individual it is essential that the stability of the family in marriage should be preserved, and social habits and customs should be adjusted to this end. (2) There is overwhelming evidence that irregular sex relations, whether in married or unmarried, lead to physical, mental, and moral harm. (3) There is no evidence either from physiology or from experience that for the unmarried sexual intercourse is a necessity for the maintenance of physical health. (4) There is no evidence either from psychology or from experience that for the unmarried sexual intercourse is a necessity for the maintenance of mental health."

This pronouncement has formed a basis for addresses delivered last year by Prof. J. Arthur Thomson, Dr. William Brown, and Prof. Julian Huxley under the ægis of universities, local authorities, and branches at 21 different towns. A medical film on the manifestations, diagnosis, and treatment of syphilis is now almost ready, and the first six sections are available for use in medical schools and by post-graduate associations. Especial effort is to be directed during the coming year to the relation between mental deficiency and the spread of venereal disease, and to the checking of congenital syphilis. The medical committee of the Council urges the need for antenatal work and the treatment of infected women during pregnancy.

SILKWORM DISEASE.

PEBRINE began to make itself felt in the French silk industry in the 'fifties of last century. For a time the cultivators kept going by importing clean eggs from uninfected districts, and, indeed, reached their maximum production (26 million kilos of cocoons) in 1853. Despite all their efforts, however, the yield steadily fell after that until in 1865 only some 4 million kilos were obtained. Various individuals and commissions examined the matter, and Cornalia described the corpuscles which are now known as *Nosema bombycis*, but nothing was achieved towards the practical suppression of the disease. It is said that Pasteur, when he was asked by Dumas in 1865 to see what he could do, did not know that a caterpillar turned into a chrysalis and a chrysalis into a moth. That pebrine is now a thing of the past is sufficient evidence that this sort of ignorance does not matter very much to a man with a flair for experimental inquiry and a belief in the efficacy of microbes in causing disease. All Pasteur's writings

on silkworm diseases are collected in a noble volume,[1] the fourth of his collected works, by the pious care of Dr. Vallery-Radot. Three more volumes are promised, and the whole collection will form a splendid monument. The reproduction of the originals is, as far as a few test pieces go, meticulously correct, and the only thing we regret is that no footnotes or running commentary has been added to show the present state of the various hares that Pasteur started. Classical texts are edifying enough, but for those who have little knowledge of the subjects dealt with they are all the better for prolegomena, notes, and appendices.

ETHYLENE ANÆSTHESIA.

ETHYLENE has only been in use, at all commonly, for three years and it may be still too early for a confident pronouncement on its exact place among available anæsthetics. Nevertheless, there are certain advantages and certain defects which are already so clear that the permanent value of this drug may be fairly gauged. For major operations, where complete muscular relaxation is required, it is obviously not in the same class as ether. On the other hand, it is more potent than nitrous oxide and can be used effectively with higher proportions of oxygen, which makes it a valuable aid where a patient is very feeble or ill. It is, in fact, for short operations on this type of person that ethylene is likely to be chiefly employed. The after-effects are slight, but so also are those of nitrous oxide and oxygen in similar cases. A writer in *Surgery, Gynecology, and Obstetrics* for November advances the claims of ethylene over "gas and oxygen" from the point of view of safety. His premises, however, do not seem correct, for he refers to the danger of nitrous oxide and oxygen in unskilled hands—a danger that exists, no doubt—but to the safety of ethylene properly employed. The truth appears to be that both these anæsthetics are quite safe for short operations, but either of them may cause deaths during long administration. We gather from the article quoted that both chloroform and ether are viewed with greater disfavour on the other side of the Atlantic than they are here. It is just possible that through an eagerness for improvement anæsthetists in the United States have not sought or obtained from the older drugs the best that they can give.

A STUDY OF INCIDENCE OF ILLNESS.

A REPORT of the U.S. Public Health Service, dated Sept. 24th, 1926, contains a useful study of the incidence of sickness in the town of Haggerstown in Maryland during a period of 28 months. This town has a population of about 30,000, mostly white, and the investigation was limited to these. The study comprised some 1600 families selected for their representative character, and because of convenience for repeated visiting. After a preliminary visit, at which exact information was obtained, there followed 16 subsequent canvasses at intervals of from six to eight weeks. The data thus obtained as to illnesses which lasted at least three days are suggestive. Mr. Sydenstricker, statistician of the Public Health Service, gives the following as among the broad results obtained. An illness-rate of slightly more than one illness per person per year is indicated, the term illness being used as exclusive of attacks—for instance, of catarrh—which did not result in illness. This rate is about ten times as high as the rate for illnesses causing absences from work for eight days or longer among adult male industrial workers in a group of American industries. Nor is this surprising in view of the fact that the Haggerstown statistics include young children and aged people, as well as adults of intermediate ages. As in the English statistics of medical work under the National (Health) Insurance Acts, it is striking how low is the position occupied by tuberculosis, cancer, cardiac diseases, and renal diseases in the causes of illness during the 28 months' observation. The inference is drawn that these serious causes of mortality are actually less frequent as causes of illness than the illnesses which most of us at intervals experience. This conclusion needs tempering, of course, by consideration of the extensive treatment of these more serious illnesses in hospitals and infirmaries. Colds and bronchitis caused illness in 419 per 1000 persons in the group under observation; influenza and "grippe" in 143, digestive diseases 95, tonsillitis and sore-throat 65, puerperal conditions 46, accidents 40; the numbers under other headings becoming smaller and smaller, until we reach the lowest point of the scale, where appear pneumonia with 7, diphtheria, scarlet fever, and typhoid (aggregate) 6, hay fever and asthma 5 cases per 1000 persons. That death-rates are not a suitable index of illness is shown by the fact that in Haggerstown only 20 per cent. of the mortality, but 61 per cent. of the illnesses were due to respiratory diseases. Mr. Sydenstricker's report contains other observations worthy of note, and these are to be the subject of further study.

RESEARCH IN CLINICAL PSYCHIATRY.

AT the quarterly meeting of the Royal Medico-Psychological Society held at the Horton Mental Hospital, Epsom, on Nov. 16th, a resolution was put calling for the institution of a preliminary Research and Clinical Psychiatry Committee. In a letter circulated to the members of the Association prior to this meeting, the President, Lieut.-Colonel J. R. Lord, expressed the view that such a committee should be composed mainly of medical officers actually engaged in research and higher scientific psychiatry, with the addition of representative teachers in psychiatry, clinicians of note and standing, psychologists, sociologists, and some interested in statistics. The committee, he thought, should be a large one to permit of good attendances at meetings and the group consideration of sections of work such as ætiology, symptomatology, treatment, classification, records, and statistics. At the meeting the President was able to report an encouraging response to this letter, and the receipt of many helpful suggestions from members. He reiterated the view that every member should either have definite work to do for the Association or some direct interest in it. Resolutions were unanimously passed appointing a preliminary committee to prepare the way for the Standing Committee to be set up under the charter. Local authorities are being asked to afford facilities for the holding of divisional clinical meetings, to which local practitioners will be invited, and to encourage all assistant medical officers to attend these meetings.

POOR-LAW HOSPITAL EXTENSION AT LEEDS.—The Leeds board of guardians is considering the reorganisation of its hospital system. An extension of St. James's Hospital has just been opened and Dr. J. Dick, assistant medical superintendent of Fir Vale Hospital, Sheffield, has been appointed its medical superintendent and chief medical officer of the union. The guardians have also under their control two other hospitals at Bramley and Rothwell respectively. It is proposed so to enlarge that at Bramley that it will ultimately accommodate from 800 to 900 patients and become a training school of the same type as St. James's. The arrangements at St. James's for visits by consultants are to be extended, and it is intended that there shall be two visiting surgeons, three visiting physicians, a gynæcologist, an aural surgeon, and an ophthalmic surgeon, and that the resident staff shall consist of six house surgeons and physicians who will work under the visiting surgeons. The latter will have their own patients, and will be at liberty to call in other consultants on agreed terms. It is further proposed to appoint a pathologist and bacteriologist, to set up a separate X ray department, and generally to develop the infirmary on the lines of a general hospital.

Modern Technique in Treatment.

A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions.

CC.—THE TREATMENT OF CHILBLAIN (ERYTHEMA PERNIO).*

I.—General Considerations.

BEFORE discussing the pathogenesis of the actual lesion of chilblain it is convenient to consider the ætiology of the condition called "chilblain-circulation," acrocyanosis, or acroasphyxia, which is its usual accompaniment. It must however be recognised that chilblains may, rarely, occur in persons whose peripheral circulation is normally good, and conversely that a "chilblain-circulation" is not necessarily complicated by their development. Although patients liable to chilblains are not, as a rule, cases of Raynaud's disease, yet the latter often give a history of chilblains in childhood.

The Fat Subject of Acrocyanosis.

The subjects of acrocyanosis may roughly be divided into two types—the fat and the thin. The former is best exemplified by the blue-legged young woman, whose lower extremities have recently been the subject of some discussion in connexion with the wearing of silk stockings. This type is practically confined to the female sex, and presents the following clinical characteristics.

The patient is usually between the ages of 15 and 25, but the symptoms may persist until late middle age and may become accentuated at the menopause. She is fat, phlegmatic, and mentally often rather dull. The skin is harsh and dry on the extensor surfaces of the limbs, where there is also well-marked keratosis pilaris, particularly in the regions in which the cutaneous vascular stasis is most evident—viz., the posterior surface of the upper arms and the legs below the knees. Even in summer the peripheral vascular stasis can be recognised, especially in the lower halves of the legs, and in cold, damp weather it reaches its maximum. The lower extremities show an increasing degree of cyanosis from the thighs downwards; above the knee there is livedo, below it there is a diffuse dilatation of the cutaneous vessels which is most evident on the lower postero-external surface. Here the skin is of a livid purple colour and icy cold to the touch. It is in this situation, where the vascular stasis is most marked, that the hypodermic nodules of Bazin's erythema induratum arise, should the patient have an active tuberculous focus with bacteriæmia, and it may be remarked that Bazin's disease is hardly ever met with except in patients of this type; apart from true erythema induratum chilblains may occur and give rise to a real difficulty in the differential diagnosis. Around the pilo-sebaceous follicles, the site, as has been said, of keratosis pilaris, are little blue rings of venous stasis, and the lanugo hairs are coarse and long. The skin is bound down to the subcutaneous fat and cannot be pinched up, and both it and the underlying tissue give the impression of being œdematous. Moreover, in severe cases there is actual œdema of the lower part of the legs, ankles, and feet, with pitting on pressure. To a less degree there is the same vascular stasis, with circumfollicular halos, keratosis pilaris, and sensation of œdema on the extensor surfaces of the upper arms. Livedo may be apparent on the forearms, and the hands are blue, cold, and often clammy; their dorsal surfaces and the fingers may be swollen and œdematous, and covered with chilblains of varying severity. In many of these patients there are menstrual irregularities; puberty is often retarded and the periods scanty and infrequent. This is not, however, constant.

The ætiological factors responsible for these characteristics must at present be regarded as uncertain and perhaps complex. The majority of patients are girls who live a sedentary indoor life and whose diet is lacking in fresh vitamin- and mineral-rich food, and it is probable that in the ætiology of the underlying endocrine disturbance, heredity, an unsuitable dietary, lack of fresh air and sunlight, and chronic septic absorption or intestinal toxæmia may all play a part.

The Thin Subject of Acrocyanosis.

To come now to the thin type of person with acrocyanosis, examples are met with in both sexes, and the symptoms may begin in early childhood—i.e., before puberty.

The patients are usually of a nervous and emotional temperament in contrast with the phlegmatic calm of the first type, and muscular hypotonus, with a resulting faulty stance and visceroptosis, is a characteristic feature. Loss of vasomotor tone is shown by a tendency to alternate pallor and flushing, by the coldness and blueness of the extremities, and by the static albuminuria sometimes found. This thin type, too, is more susceptible to infection, so that persistent nasopharyngeal catarrh, recurrent attacks of tonsillitis, and tuberculosis are common.

In childhood transient arthritis, endocarditis, and chorea, and in adult life chronic rheumatoid arthritis are found much more commonly in patients of the thin than of the fat type. The latter are also often subject to catarrh, and may develop tuberculosis of the lymphatic glands, in which case, as has been said, Bazin's erythema induratum is a likely complication, but their resistance to infection is undoubtedly greater. In other words, whereas liability to various infections is common to both, the constitutional disturbance is greater and permanent damage to certain organs and structures more likely to occur in the thin type.

The Hyposphyxial Syndrome.

Reference may here be made to the hyposphyxial syndrome or "hyposphyxia" of Alfred Martinet,[1] under which term the author gives an accurate clinical description, chiefly as regards the circulatory system, which applies to both the types differentiated above.

An appreciation of this hyposphyxial state is important because the sluggish circulation not only interferes seriously with the general tissue metabolism, but also predisposes to the development of cutaneous and other diseases when a chronic infection is present, since circulating bacteria may become embolised, and their toxins are more likely to produce inflammatory reactions, in situations where the vascular stasis is greatest.

Thus erythema induratum and papulo-necrotic tuberculide, which are respectively subcutaneous and cutaneous tuberculides, are seen only in hyposphyxial persons, and are due to the embolism of tubercle bacilli, carried in the blood stream from some distant tuberculous focus and coming to rest in a subcutaneous or dermic vessel. The hypodermic nodules, described by Dr. Whitfield as the non-tubercular form of erythema induratum and as occurring exclusively in middle-aged women suffering from chronic rheumatism, are similarly due to embolism of streptococci and, perhaps, other organisms.

Lupus erythematosus in its distribution affords a beautiful example of the localising influence of circulatory stasis in a chronic infection. The actual eruption may be due both to circulating toxins and to an actual bacteriæmia: its sites of election are the butterfly or flush area of the face, the ears, and the fingers, and its incidence in the last situation appears to be directly proportional to the degree of the coincident chilblain circulation.

The Actual Lesions in Chilblains.

The mechanism of the production of the actual lesion of chilblain is not altogether clear. There is presumably an initial contraction of the small arterioles and capillaries in response to the stimulus of cold, followed by a reactionary vasodilatation. This secondary vasodilatation appears to be accompanied by increased permeability of the vessel wall, with the result that serum, occasionally blood-stained, oozes into the tissues and produces a firm nodule of localised œdema over which the epidermis is stretched. Sometimes the exudation is so intense that an actual bulla is formed, the roof of which is constituted by the entire epidermis. In any case the latter is apt to be damaged, with the formation of a so-called "broken" chilblain. The ulcerated surface thus produced may become secondarily infected, and in severe cases there is considerable tissue-destruction with scar-formation. Not infrequently, if the chilblain condition of the skin persists, a thickening of the horny layer takes place and obstinate painful fissures result. Though usually discrete, chilblains may become confluent, and in the

* An article in this series on the Treatment of Chilblains—II. The Management of the Case, by Dr. Barber—will appear in THE LANCET next week.

[1] Presse Médicale, 1912, xx., 1064.

worst cases the fingers and even the whole hand may be swollen, œdematous, and covered with painful ulcers and fissures. Subjectively the lesions give rise to sensations of burning and intense irritation, causing the patient to scratch and deliberately relieve the tension by breaking through the distended epidermis.

Ætiology.—The ætiology of chilblain has already been partially dealt with in the above discussion on acrocyanosis, which is one of the most important predisposing factors. There are, however, several points which must be further considered. The influence of cold is obvious, and the combination of cold and damp is particularly noxious. Given, however, a feeble peripheral circulation, the question arises whether the mere physical action of cold alone on the local vasomotor mechanism is sufficient in itself to produce the lesions of chilblain, or whether cold acts by merely intensifying the vascular stasis already present. As has been pointed out by Dubreuilh and Petges,[2] there is a very close resemblance between chilblain and erythema induratum both anatomically (Audry [3]) and clinically. In fact, one might regard the latter as a subcutaneous chilblain just as the common form of erythema nodosum (in spite of assertions that have been made to the contrary) is undoubtedly the subcutaneous variety of erythema multiforme and angeioneurotic œdema a subcutaneous urticaria.

The suggestion, however, made chiefly by French writers, that chilblains should be considered as a superficial form of erythema induratum, and therefore as a tuberculide, cannot be accepted.

At the same time there is considerable clinical evidence that chilblains may actually be due to bacterial embolism or to the action of bacterial toxins on the cutaneous vessels, thus bringing them into line with erythema multiforme, erythema nodosum and induratum, and lupus erythematosus.

For example, a woman who suffered from Raynaud's disease, with early sclerodactyly, but who had never had chilblains, was operated on for appendicostomy; shortly after the operation an acute *Bacillus coli* infection developed with high temperature of the septicæmic type. In spite of the fact that she was, of course, completely at rest in bed, this febrile attack was accompanied by the appearance of large numbers of typical chilblains on the hands and feet. With the subsidence of the infection they disappeared and have never returned.

The influence of cold could not be invoked in this case, and one can but conclude that the chilblain lesions were produced by a bacteriæmia, with embolism in the cutaneous vessels, or, which is less likely, by the action of bacterial toxins.

Lastly the view, put forward by Sir Almroth Wright, that chilblains, urticaria, angeioneurotic œdema, and the so-called physiological albuminuria are due to lowered coagulability of the blood, which allows the transudation of plasma through the vessel walls and which is associated with a deficiency of calcium, must be referred to. It is responsible for the treatment of these conditions by the internal administration of calcium. Wright's view is certainly not universally applicable.

Dr. W. Payne has kindly estimated the total and ionisable calcium in a few young girls of the fat, acroasphyxial type. In none of them did the figures indicate calcium deficiency, and in some they were above normal. This corresponds with my clinical experience that chilblains in this type of patient are seldom relieved by calcium lactate, whereas the simultaneous administration of thyroid gland and large doses of iodine is usually of great value. On the other hand, calcium salts, parathyroid gland, and cod-liver oil are often very effective in the thin, hypotonic, scrofulous patient with acroasphyxia, not only in improving the general condition and resistance to infection, but also in lessening the tendency to chilblain.

Special Articles.

PARIS.

(FROM OUR OWN CORRESPONDENTS.)

The Treatment of Poliomyelitis by Irradiation and Diathermy.

IN 1911 Prof. L. Bordier, of Lyons, successfully treated a case of chronic anterior poliomyelitis (Aran-Duchenne type of progressive muscular atrophy) by the application of X rays to the cervical cord, and this led him to use radiotherapy for the treatment of acute poliomyelitis in children. His first results were published in 1921.[1]

During the first fortnight of an attack there is diffuse meningomyelitis of the spinal cord with œdema and hyperæmia. This leads on to atrophy of the motor cells of the anterior horn, and the result is paralysis and trophic disturbance in those muscles whose innervation corresponds to the affected neurons. Treatment with X rays is directed against the central cause of the paralysis, and it is claimed that irradiation diminishes œdema, reduces the small-celled infiltration, and promotes resolution of the inflammatory processes.[2] Experimentally and clinically it has been proved that the application of X rays to the spinal cord of young subjects is without danger.[3]

Radiotherapy, according to Prof. Bordier, ought to be started as soon as possible after the end of the febrile period. The exact site of the lesion can be discovered, if necessary, by testing the electrical reactions of the muscles, and X rays are then applied to the spinal cord at the appropriate level. The dosage needed is about 200 units R at a sitting; 600 R, or three units H, may be given during three successive irradiations, through a filter of 6 mm. of aluminium; and the operator makes use of either one or two ports of entry according to whether the paralysis is unilateral or bilateral. The direction of the beam of X rays ought to be perpendicular to the vertebral discs,[4] and the X ray tube and the patient are, therefore, arranged so that the angle between the principal plane of the tube and the sagittal plane of the body shall be 25 degrees (cervical region) or 30 degrees (dorso-lumbar region). After a course of treatment there is an interval of 25 days; two or three courses may be given according to the state of the patient.

The second therapeutic agent recommended by Prof. Bordier is diathermy of the muscles, which is intended to increase the blood-supply and temperature of the tissues, and thus promote better nutrition of the whole paralysed limb. Diathermy, he states, should be used from the beginning, independently of irradiation, and should be continued until the normal temperature of the limb permanently returns. It can be given daily, or at longer intervals. The technique is simple. A patient whose lower limb is to be treated is made to sit down on a metal electrode, and a second electrode is applied to the sole of his foot. The amount of current should be moderate, and the séance lasts about ten minutes.

Lastly, electrotherapy is valuable, as generally recognised, to restore the tone and function of paralysed or atrophied muscles. This is the third phase of treatment, and needs to be continued for a long time.

Since Bordier's combined method has been put forward it has given very encouraging results, both in his own hands[5] and in those of many others.[6] It has been criticised, of course, and he has replied

to the objections[3]; and his opinions have recently received experimental confirmation.[7] Though the treatment cannot at once cure the more serious cases, where there is a complete reaction of degeneration in many muscles, it considerably improves the prognosis and mitigates the consequences of the disease. In most cases of moderate gravity there is a favourable response, and in view of the unsatisfactory results of other methods, that put forward by Prof. Bordier appears well worth trial.

A Study of Suicide.

Under the direction of Prof. P. Toulouse, chief of the dispensary for mental prophylaxis, Dr. Suzanne Serin has just completed a study of suicide as occurring in Paris, and has examined 307 cases. The study shows that suicide is most frequent among males, aged persons, and the unmarried, and that, in spite of the large foreign population in Paris, suicide is limited almost wholly to the French. The main causes are psychopathic states, alcoholism, private cares, incurable disease, and poverty. One-third of the cases she regarded as of psychopathic origin, and half of these presented distinct mental abnormalities, including melancholia, dementia præcox, epilepsy, and traumatic psychoses; the other half showed defective mental balance in alcoholic or epileptic individuals, where suicide was not, she thought, directly related to the alcoholism or epilepsy. Another third of the cases proved directly due to alcoholism itself, apart from alcoholic mental affections. Prevention of suicide, says Dr. Serin, is most difficult in cases of poor mental equilibrium, for here suicide cannot be foreseen. Fairly effective prevention should be practicable in psychopathic cases through more careful organisation of mental dispensaries, clinics, and similar institutions.

The Centenary of Pinel.

Philippe Pinel died in 1826 at the age of 81, and the Academy of Medicine has been celebrating his centenary. Prof. Achard gave a masterly account of his life and works, referring especially to his "La médecine rendue plus précise et plus exacte par l'application de l'analyse (1802)" and his "Nosographie Philosophique," which was as a code of medicine for all his generation. Pinel spent most of his time in studying mental disorders, and wrote in 1809 a medico-philosophical treatise on insanity. To disorders of the understanding he tried to apply the same processes of reasoning as were used in ordinary medical practice, and he made great efforts to introduce more humanity into the conduct of asylums and to put an end to the fierce conflicts—far too common in those times—between attendants and patients. In the eyes of posterity this is perhaps his principal claim to glory.

Prof. Le Dentu.

One of the masters of French Surgery, Prof. J.-F.-A. Le Dentu, member of the Academy of Medicine and Commander of the Legion of Honour, has died in Paris at the age of 85. He was formerly surgeon to the Hôpital Necker and the Hôtel Dieu, and was professor of clinical surgery in the Faculty of Medicine from 1890 to 1908. He published a number of standard works on operative technique, and in collaboration with Delbet edited a treatise on Surgery in ten volumes.

The Argentine Republic has sent Prof. Enrique Feinmann to study French and Swiss clinics for the treatment of industrial accidents and diseases. He will also examine the organisation of European ministries of labour.

A centre for the re-education of the deaf has been opened by Dr. G. de Parrel at 78 boulevard Malesherbes, Paris.

On Nov. 6th the honorary degree of M.D. of the University of Paris was conferred on Dr. O. Medin, of Stockholm, especially known for his work on epidemic anterior poliomyelitis, and on Dr. C. Chagas, of Rio de Janeiro.

BUCHAREST.

(FROM OUR OWN CORRESPONDENT.)

Strong Measures against Venereal Disease.

A GOVERNMENT Bill embodying the recommendations of many medical authorities is now before the Chamber of Deputies and is likely to become law within a short time. Among the Bill's provisions is one compelling doctors to notify the name of any patient suffering from venereal disease who stops having treatment whilst still a danger to his neighbours. On receiving such a notification the magistrate-doctor will refer the patient to a centre for compulsory treatment. Any person reported to be a source of venereal infection, as well as those who have suspicious-looking rashes, may be compelled to undergo examination by an official doctor unless he can produce a medical certificate stating that he is having treatment or is healthy. Magistrate-doctors will also be obliged to examine every month all boys and girls over 15 years of age in secondary schools, besides hawkers, domestic servants, and many other classes of the community. All those subjected to this monthly examination, except school-children, will be given a health-card which they will have to carry about with them. Where patients are likely to infect others whilst undergoing out-patient treatment they may be forcibly put into hospital. The Bill contemplates such restraint in the first place, for tramps and prostitutes, and in the second for kitchen-maids, waiters, and other public servants, if suffering from oral lesions, facial rashes, and the like. To ensure their adequate accommodation the State will provide funds to aid municipalities in setting up the necessary institutions. The Bill lays down that an infected person is entitled to moral and financial compensation from the one who infected him. Individuals who have infected many others will be prosecuted by the health authorities, even if the violated parties do not demand it. To establish the fact of infection, a thorough investigation must be made and the case must be submitted to a specialist in venereal disease; where syphilitic infection is alleged, the claim must be made within four months from the date of infection. The Bill promises very serious punishment for syphilitic nurses who infect healthy infants and for parents who employ a healthy woman to nurse a syphilitic baby, or board out a syphilitic child with healthy people. No person suffering from any venereal disease will be allowed to marry until completely cured, and registrars will demand a medical certificate from all candidates for marriage, stating that they are free from such disease. Registrars will also be obliged to distribute booklets explaining the perils of venereal diseases to those whose marriages they record. As regards prostitution, the Bill states that only girls above 18 years of age may get licences. Girls younger than 18, if presenting themselves for registration as prostitutes, are to be placed under the care of their parents or else put in reformatories. Where girls wish to give up prostitution the competent magistrates will have to place them in institutions or refer them to employment bureaus, where they can get decent work. The new law is going to ensure the success of the campaign against venereal disease by setting up an antivenereal office, which will have the duty of controlling and supervising prostitution. This office will be provided with special health and morality police, who will, in fact, be detectives.

A Source of Income for Dentists.

Some time ago a dentist called Anbock settled in Cluj and by reason of good connexions soon developed a large practice. His method of treating the teeth was very simple. He told the patients that the gold fillings in their teeth were useless and vile work, that

the alloy was bad, and that it had to be changed. He began his methodical treatment by picking out the gold from the properly made fillings; when the teeth again became painful he replaced the gold with a valueless yellow alloy which, he said, was pure gold, prepared after his special method, patented in all foreign countries. By the time that the patients had begun to feel a peculiar taste in their mouths the eminent dentist had made his escape. The unfortunate patients were informed by other dentists that the fillings which the swindler had put in were only exploratory fillings, and accordingly reported their misfortunes to the police. The culprit, however, has moved on to Jugoslavia.

Prohibition of Secret Remedies.

The Bucharest Health Board has issued an order that all so-called patent medicines be removed from drug stores and chemists' shops within three months. These drugs are called secret remedies in Rumania because they bear on the label no indication of the ingredients they contain. Instructions have been issued to all custom houses that no foreign medicinal preparations of this kind be allowed to enter the country, even if marked as samples of no declared value, and any custom house officer convicted of permitting such medicines to pass will be suspended from his position.

IRELAND.

(FROM OUR OWN CORRESPONDENT.)

County Medical Officers of Health.

UNDER the Local Government Act, 1925, it became the duty of county councils throughout the Irish Free State to appoint whole-time medical officers of health for each county. Last week the Department of Local Government and Public Health sent a letter to the several councils, reminding them of this duty, and offering to send a medical inspector to explain their position. The reception so far given to the letter has been chilling. The Galway and Wexford councils have flatly declined to take any steps, and several other counties have postponed a decision. It will evidently require more than moral suasion to get the local authorities to move. A salary of £800 was mentioned in more than one county as suitable for their medical officer, though there are few, if any, areas in the Free State in which the salary, on the British Medical Association scale, should not be at least £1100. As most of the supply of medical officers of health must come from England, an attractive salary will be necessary in order to secure competent men. Again, some of the inspectors seemed to suggest that the county medical officer of health should be a jack-of-all-trades, that he should personally be occupied in the medical inspection and treatment of school-children, and in such duties. It is unfortunate that the Minister has, as yet, taken no steps to set up a consultative council, such as is provided for by the Act.

The Milk Supply of Ireland.

The Government of the Free State has recently appointed a Commission on Milk Supply, and last week it was engaged in hearing expert evidence. Dr. J. W. Bigger, professor of bacteriology and preventive medicine in the University of Dublin, urged the grading of milk, and suggested three grades in addition to pasteurised milk, the highest being from tuberculin-tested cows. There was at present no incentive, he said, to supply pure milk, as the price charged was the same as that paid for impure milk. Penalties should be imposed on anyone who sold milk below a specified standard; if the practice persisted the penalty should be exclusion from the milk trade. Dr. J. D. McCormack, Local Government Department inspector, attributed the apathy of local authorities in regard to the Dairies Order to want of knowledge. He recommended closer coördination between urban and rural authorities. A maximum price for milk should be fixed according to grade. Mr. O'Donovan, veterinary surgeon, giving evidence on behalf of the Dublin Corporation, said that the corporation staff should have power to supervise milch cows belonging to the city, even when removed for summer grazing outside the county borough area, and also to supervise the sources of rail-borne milk, where tubercle bacilli had been found.

The first general meeting of the Irish Clean Milk Society was held on Nov. 25th, when Mr. W. Buckley, Chairman of the British National Clean Milk Society, gave an address. He said that America was 25 years ahead of Great Britain so far as the milk-supply was concerned, and pointed out that a great deal more could be done by education than by coercion.

A National Medical Service.

At the annual meeting of the Association of Trade Union Approved Societies held recently the President, Mr. L. W. Duffy, made a strong plea for a national medical service in the Irish Free State. He said that every country in Europe, except Ireland, had rejected the British system of approved societies. The societies had degenerated into benefit-paying organisations on the lines of the old tontine society, and no serious effort was made to prevent illness or cure disease. The mortality from tuberculosis was again on the increase, and the maternal mortality was alarming. Medical benefit on a contributory basis was no substitute for a national health service, and when the public realised what was at stake, and began to appreciate the ravages of the present system, they would demand a national service, even if it were to cost twice as much.

Cancer Research in Dublin.

The principal Irish medical colleges and schools, as well as other bodies, are represented on the committee of the Cancer Research Institute which is to be set up in connexion with the Royal City of Dublin Hospital. Mr. Justice Wylie has been appointed chairman of the committee, Dr. Louis Cassidy honorary secretary, and Mr. Hubbard Clark honorary treasurer. The hospital is going to take over the Erlangen apparatus hitherto worked at the Coombe Hospital, and will furnish a laboratory with other facilities for research work; but Sir John Lumsden, a member of the committee, has denied the report that the committee has been formed to carry on the Erlangen treatment. Its object, he says, is not to advocate any particular form of treatment, but to investigate the origin and treatment of cancer.

JAMES MACKENZIE INSTITUTE FOR CLINICAL RESEARCH.—On Nov. 9th Prof. Ashley Mackintosh reviewed the groups of causes known to influence or coöperate in the production of arterio-sclerosis, and emphasised the importance of removing them. They included "tear and wear," especially from worry, and infective or toxic causes not necessarily of gastro-intestinal origin. In this connexion he professed himself a believer in an hereditary variation in the viability of the vessels. Prof. Mackintosh was emphatic in his statement that the sufferer from hypertension should be prevented from concentrating his attention on his malady, and for this reason deprecated the too frequent recording of blood-pressure readings, which led to a "hypertension hypochondriasis" (Osler and McCrae). He found greatest benefit from a mode of life which involved as little interference as possible with habits, work, and food, especially in elderly patients. He did not drastically reduce protein but allowed 3–5 oz., especially of white meat, per day, believing that too much stress had been laid on the dangers of giving protein. Diets must not be cut down so far as to lower the patient's general condition. He outlined the proper care of the skin and bowels and strongly advocated the weekly or bi-weekly use of calomel. Before describing other medicinal treatment he discussed the question how far hypertension was a compensatory function, and showed that it was not apparently compensatory so far as the kidney was concerned, there being no proved relationship between the power of concentrating urea and the blood pressure. Prof. Mackintosh referred to other methods of treatment by venesection, by electrical methods, and especially by diathermy, and in conclusion urged the importance of watching the heart carefully.

MEDICINE AND THE LAW.

An Unregistered Specialist.

WHAT is a "specialist"? If a man calls himself a specialist in canine diseases, does not the description amount to a claim that he is "specially qualified" to practise veterinary surgery or some branch thereof within the meaning of Section 17 of the Veterinary Surgeons Act of 1881? Mr. Gill, the Westminster Police-court magistrate, has answered the latter question in the affirmative. A blacksmith who advertised his business as including "veterinary farriery" was held in 1892 to be within the section; so also was a defendant who used the description "canine specialist; dogs and cats treated for all diseases"—this being the decision in Royal College of Veterinary Surgeons v. Collinson ([1908] 2 K.B., 248), which Mr. Gill expressly followed. Section 17 punishes with a fine not exceeding £20 anyone who, not for the time being on the register of veterinary surgeons nor having been on August 27th, 1881, the holder of the veterinary certificate of the Highland and Agricultural Society of Scotland, "uses the title of veterinary surgeon or veterinary practitioner, or any name, title, addition or description stating that he is a veterinary surgeon or a practitioner of veterinary surgery or any branch thereof, or is specially qualified to practise the same." The defendant in the recent case was Mr. Edward Sewell, described in the *Times* report as having been for many years in practice as a veterinary surgeon and canine specialist in South Kensington. He used the offending words "specialist, canine diseases" on the receipt to a bill. It was argued on his behalf that recent decisions have shown a trend towards greater laxity in favour of the unregistered practitioner. Mr. Gill, however, did not agree; he fined the defendant £2 and £10 10*s.* costs, and undertook, if desired, to state a case for a higher court.

The comparative effect of professional registration is well known. No unregistered dentist may practise, or hold himself out as practising or as being prepared to practise, dentistry—an absolute monopoly. No unregistered veterinary surgeon may call himself a veterinary surgeon or veterinary practitioner—a substantial monopoly. But, as was mentioned lately when discussing Lieut-Colonel Kynaston's case, an unregistered medical practitioner has (subject to limitations as to signing death certificates, &c., and as to the Dangerous Drugs Acts) full liberty to practise, so that the registered medical practitioner has virtually no monopoly at all.

Sale of Poisons: Lysol "free from Carbolic Acid."

The Pharmacy Acts and the various enactments about poisons are so complicated that it is high time the law was simplified. Administration, too, might be coördinated, even if this involves the surrender by the Privy Council of some of its surviving powers in this respect. Two months ago an Edinburgh prosecution under the Pharmacy Act in connexion with the sale of a bottle of "lysol" drew fresh attention to the obscurity of the law. As experts are aware, there is a subtle legal distinction between the label "Poison" and the label "Poisonous." Section 17 of the Pharmacy Act of 1868 (amended by the Dangerous Drugs and Poisons (Amendment) Act of 1923) requires that poisons shall be labelled with the word "Poison," the name of the poison, and, if poison is merely one of the ingredients of a preparation, with particulars of the proportion of the poison to the other ingredients. The poisons which must thus be labelled are those in the schedule of the 1908 Act, and certain others added by the Privy Council on the recommendation of the Pharmaceutical Society. The schedule includes "carbolic acid and liquid preparations of carbolic acid and its homologues containing more than 3 per cent. of those substances," with certain exceptions for sheep-wash and other agricultural and horticultural preparations. Another part of the 1908 Act (Section 5) says that certain acids are not to be sold by retail unless the bottle or vessel containing them is labelled with the name of the substance, the word "Poisonous," and the name and address of the seller. The acids include sulphuric, nitric, and hydrochloric acid, soluble salts of oxalic acid and other substances prescribed by Order in Council; an Order in Council of 1912 added "all liquid substances sold as carbolic or carbolic acid or carbolic substitutes or carbolic disinfectants containing not more than 3 per cent. of phenols."

Last September an Edinburgh druggist's assistant sold a bottle of lysol. On the carton were the words "Free from Carbolic Acid." It was labelled "Poisonous," and to that extent it complied with Section 5 of the 1908 Act; but it was not labelled "Poison," and so it did not comply with the amended Section 17 of the 1868 Act. The assistant was summoned for having failed to comply with the latter requirement, the lysol being "a liquid preparation containing more than 3 per cent. of carbolic acid and its homologues." A report of the case published in the *Analyst* shows that Mr. J. Rutherford Hill, resident secretary of the Pharmaceutical Society, said that analysis of the bottle disclosed approximately 31 per cent. by weight of carbolic acid and its homologues, commonly known as cresols; he thought the label "free from carbolic acid" could not be true, and was misleading. The city analyst gave confirmatory evidence, but was unable to say whether the bottle contained sufficient carbolic acid to make it poisonous; nor had either witness, it appears, determined the exact amount of carbolic acid actually present. The defendant admitted selling the bottle, but said he did not know lysol was a poison. The label "free from carbolic acid" conveyed no special information to him; he knew nothing of carbolic acid or its effects. The sheriff held the charge not proven on the ground that there was no definite proof before him of the presence of carbolic acid in the bottle or of its presence in a quantity making the liquid a poison within the schedule. He remarked that the label "free from carbolic acid" would suggest to an unskilled person that in selling the lysol he was not selling carbolic acid, and he added that only a skilled person would understand the meaning of homologues of carbolic acid. These remarks suggest that, even if the missing proof had been abundantly supplied, the sheriff would have hesitated to inflict a heavy penalty upon the druggist's assistant. In other words, though ignorance of the law is no excuse, the law is in so technical a state that magistrates will not punish the ordinary citizen for breaking it.

Vaccination: Conscientious Objector's False Declaration.

It is the common experience of those who practise law in criminal courts that for some reason convictions for perjury are hard to obtain, and punishments for perjury are often lenient. Thus, prosecutions which should have the effect of deterring prospective perjurers end by deterring prospective prosecutors. Last year's Criminal Justice Act handed over to quarter sessions and to courts of summary jurisdiction the power to deal with offences under Section 5 of the Perjury Act (false statutory declarations). The delegation of jurisdiction may lead to more convictions if it also leads to still smaller sentences. Under the Vaccination Act of 1907 a parent must make a statutory declaration of conscientious objection within four months of the date of a child's birth. In a case recently heard before the Kingston justices a vaccination officer had pointed out to a parent that the latter had not completed an exemption form in respect of his infant daughter nearly 5 months after her birth. The father thereupon made a declaration at the magistrates' clerk's office that his daughter was born on May 30th, though the correct date was April 30th. The defendant pleaded that he had made an honest mistake, and added that he had been away from home when the child was born. The Bench presumably did not accept this plea entirely, for, if

successful, it would have involved acquittal. They fined the father £3, stating that they believed he had acted hastily and without thinking what he was doing.

Acquittal of Two Doctors on a Charge of Manslaughter.

On Nov. 30th at Manchester Assizes Dr. Arthur Stuart Holden and Dr. Frederick Langton Webster were acquitted on a charge of manslaughter in connexion with the death of a young woman who had succumbed in Dr. Webster's surgery. The accused were committed for trial for murder on a coroner's warrant following an inquest at Bamber Bridge on Oct. 29th, but the charge was later reduced. There was a preliminary hearing of the case before the Bamber Bridge justices on Nov. 5th and 8th. The defendants denied the suggestion that an illegal abortion had been performed and stated that the patient had died during an examination under an anæsthetic. Sir Bernard Spilsbury, who examined organs sent to him, and Dr. W. A. Simpson, acting police surgeon, who conducted the post-mortem examination, found circumstances which led them to form certain suspicions, but Dr. T. Watts Eden, who was called by the defence, said that he did not agree that there was any conclusive evidence of an instrument having being used or an operation performed. Dr. W. Fletcher Shaw and Dr. D. Dougal also gave evidence to the same effect. Dr. S. R. Wilson considered that the manner of death was consistent with death from syncope under a light anæsthetic. Mr. Justice Branson, in summing up, pointed to the irreproachable character of both accused doctors, and the jury after 15 minutes' deliberation, brought in a verdict of Not Guilty, with which the judge said he entirely agreed.

Dr. Holden and Dr. Webster were defended by the London and Counties Medical Protection Society.

Public Health Services.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

THE following are some of the statistics of four administrative counties for 1925 :—

Name of county.	Estimated mid-year population (R.-G.).	Birth-rate.	Death-rates per 1000 of the population.					Death-rates per 1000 births.	
			All causes.	Tuberculosis.	Cancer.	Resp. diseases with influenza.	Heart disease.	Infant mortality.	Maternal mort. from childbirth.
Lancashire..	1,785,500	15·9	12·7	0·88	1·27	2·7	1·7	82	5·2
Essex	958,700	17·1	10·3	0·87	1·36	1·6	1·5	52	3·0
Somerset ..	398,000	15·5	12·2	0·78	1·50	2·0	1·9	51	4·2
Gloucestershire ..	334,000	16·7	12·4	0·87	1·53	1·9	1·9	56	4·5

Lancashire.

Dr. J. J. Butterworth shows by tabular statements, diagrams, and maps the great changes during the last 30 years in various rates in the 121 districts which make up the administrative county. Thus, comparing the first quinquennium of this period with the last, the birth-rate has fallen from 28·34 to 19·13, the death-rate from 17·64 to 12·61, the infant mortality rate from 167 to 85, and the death-rate from respiratory tuberculosis from 1·19 to 0·72. The maps show that whereas in 1891–95 23 of the 121 districts had death-rates of 20 and upwards and 70 had death-rates of from 15 to 20, in 1921–25 there were no districts with death-rates of 20 and upwards, and only 7 with death-rates from 15 to 20. Other maps show that whereas in the earlier quinquennium 65 of the districts had infant mortality-rates of 150 and upwards and 46 had rates from 100 to 150, in the later quinquennium no districts had infant mortality-rates of 150 and upwards, and only 19 rates of between 100 and 150. Five of the districts have no hospital accommodation for small-pox and 12 have no accommodation for other infectious diseases. On June 30th, 1926, there were 901 county patients in tuberculosis hospitals, 677 being adults and the remainder children.

The county has arranged with 11 hospitals for the operative treatment of tonsils and adenoids, and adequate provision has been made for following-up, re-examination, and after-treatment. Under the council's scheme 598 children received operative treatment during 1925. The dental scheme has been extended and clinics established at 15 centres. The dental staff consists of seven full-time surgeons and one part-time surgeon. The scheme comprises the routine treatment of the 6-year olds and the following-up of this group in subsequent years. Apart from this routine work the dentists treat expectant and nursing mothers, children under school age, and "casuals." These last include cases made urgent by pain or abscess and cases where the child's health is suffering from the state of the teeth. It is impossible under this scheme to inspect and treat the older children. A mass of details are given in the report with regard to the sanitary circumstances of the 121 districts. Under the heading of Smoke Abatement we learn that 3129 observations were made and that the number of legal proceedings was 28. The time limit for the emission of black smoke permitted by the different local authorities varies from three minutes in the hour to the very high limit of 12. The medical officers of about a hundred districts state that there is a shortage of houses. The County Public Health Department had 66 samples of milk examined for tubercle bacilli, which were found in five of them. The officials of 28 of the local authorities submitted 366 samples, of which 39 contained tubercle bacilli. The County Health Department helped the Lancashire Milk Recording Society with its second "Clean Milk" competition, but there were only seven competitors. Out of 2990 milk samples 12·8 per cent. were reported to be adulterated, deficient or dirty, as compared with 9·4 per cent. in 1924. The samples from one vendor contained formaldehyde.

There were 178 notifications of encephalitis lethargica during the year, with 98 deaths. The districts with the highest death-rates from pulmonary tuberculosis were Litherland with 1·72, Ormskirk with 1·57, and Audenshaw with 1·45. Of the 729 midwives, 80 per cent. are qualified by examination and the remainder are "bona fide." There were 93 notifications of puerperal fever and 25 deaths. This high case-fatality is taken to indicate the incompleteness of the notification. The Registrar-General gives the number of deaths from puerperal sepsis in the county area as 41.

An inquiry was made as to the present condition of the eyes in cases of ophthalmia neonatorum reported during the years 1919 to 1923. The tabular statement appears to indicate an improvement during the later years, as the number of totally blind children was two for 1919, three for 1920, two for 1921, and none for 1922 and 1923. (During 1925 out of 14 notified cases there was one case of total blindness and five of impaired vision.) Since April, 1919, the whole of the medical and nursing staffs of the Education Committee and Health Committee have been amalgamated, and children are now being looked after by the same doctors and nurses from birth or before until they leave school. This has proved a great advantage. An experiment has been made in giving a course of lectures and demonstrations on baby management to school-girls aged from 11 to 13 at one of the centres. Those who attended showed intense interest and great eagerness to learn. The county council's child welfare area comprises 74 districts; in the remaining 47 the local sanitary authorities are responsible for the child welfare work. The orthopædic scheme will shortly be complete. For the Manchester area there is the Ancoats Hospital, with a country hospital at Windermere and six out-patient centres, with Mr. Harry Platt in charge as consulting orthopædic

surgeon. For the Liverpool area the central hospital is in Myrtle-street, Liverpool, and the country hospital at Heswall, on the Dee, with Mr. T. P. McMurray as orthopædic surgeon and Sir Robert Jones as consultant. Up to the present time five out-patient centres have been set up in the Liverpool area. The county council has purchased the Biddulph Orthopædic Hospital, which is beautifully situated in North Staffordshire, only 28 miles from Manchester, and stands in its own grounds of 91 acres. When this hospital has been made thoroughly up to date it will serve the portion of the county other than the areas allocated to Liverpool and Manchester.

Essex.

Dr. W. A. Bullough reports that 22,628 houses were erected during the five years 1920–24. The figures are not available for 1925, but he states that the rate of building is now more than meeting annual requirements, and should tend to relieve some of the gross overcrowding. A new appointment has been made of a senior clinical ("part-time") tuberculosis officer. In the absence of a much-needed central sanatorium a scheme for large extensions at Black Notley has been put forward, which, if approved by the Ministry, will result in the first up-to-date sanatorium in the county. There are now eight tuberculosis care associations in the county doing excellent work, chiefly in populous districts. At the end of 1925 the county council was the authority under the Notification of Births Act in 26 out of the 47 sanitary districts, and in order to avoid confusion and overlapping Dr. Bullough would like the county council to be the sole authority for all rural districts and those urban districts which are not education authorities. The combined medical service by which local medical officers of health become assistant county medical officers for the purpose of tuberculosis, school inspection, child welfare, venereal diseases, and supervision of midwives, and which was begun in 1920, has now been extended to 33 of the 47 districts, and Dr. Bullough, after five years' experience, is satisfied that the standard of the health services has been raised thereby.

Dr. Bullough claims that his county has the greatest number of farms producing Grade A milk.

Reviewing the situation of isolation hospitals and small-pox hospitals, he emphasises the advantages both in economy and efficiency of pooling the accommodation in all the hospitals in the county. If this were done, he says, half the isolation hospitals would serve the needs and the remaining half could be used for advanced tuberculosis, open-air schools, maternity hospitals, and convalescent homes for orthopædic patients. A greater variety of infectious diseases could also be admitted, because particular hospitals could be allocated to particular diseases. The county council is chary about undertaking the adequate examination of milk for tubercle. Thus the number of biological tests for the year ending March 31st, 1926, was limited to 15. Other matters dealt with by Dr. Bullough are: the nuisance caused by the dumping of London refuse on the low-lying land in the S.E. of the county; the progress of the town-planning scheme for the area between Shoeburyness and East Ham; and the water-supply of the county. The Stour appears to be one of the most likely sources for future needs, but this river belongs to Suffolk. Other possible sources are the rivers Colne and Roding. The county sanitary inspector deals with some of the difficulties in obtaining a pure milk-supply owing to the deep-rooted objection of a certain class of cowmen to any change in habits.

Somerset.

Dr. W. G. Savage reports 52 notifications of encephalitis lethargica, with 24 deaths. He, like Dr. Bullough, condemns the present wasteful and unsatisfactory system of having a number of small isolation hospitals under different authorities scattered through the county, whereas, "with present facilities for travel, a few hospitals could well serve the needs of the county with economy in cost and a great improvement in the quality of treatment provided." The county sanatorium at Quantock was opened in June, 1925, with 61 beds, 30 for men and 31 for women. The results after a year are very encouraging. The number of contacts attending the dispensary for examination was 21·9 per cent. as compared with 20·8 per cent. in 1924. Over 32 per cent. of the pulmonary tuberculosis contacts showed suspicious or definite signs of tuberculosis in both years. Unused buildings at Quantock were utilised as a summer camp for weakly children with most satisfactory results. Dr. L. J. Short, the tuberculosis officer, reports that of 1589 new cases examined 495 were diagnosed as having pulmonary tuberculosis. Of these 495, 203 were only in stage 1, "and experience has shown that nearly all these are likely to get well." Every year, says Dr. Short, it has been possible to write off a number of persons as cured and unlikely to relapse, and the number of ex-patients in full regular work continues to increase. These results are so very different from those reported elsewhere that Dr. Short cannot help wondering if there is something specially favourable in the Somerset air, constitution, or tuberculosis scheme. Trained midwives attended 53·8 per cent. and "bona fide" midwives 2·6 per cent. of the births. The trained midwives sent for medical aid in 27·5 per cent. of their cases, the "bona fide" in 11·9 per cent. There were 22 notifications of puerperal fever with 10 deaths, and Dr. Savage would like to see these cases removed in the early stages to hospital. The isolation hospitals would be the most suitable if an efficient staff were available. There were 30 notifications of ophthalmia. Though there was no complete loss of sight, there were four cases with probable definite impairment of vision. Here again Dr. Savage advocates immediate hospital treatment for all severe cases. In September a comprehensive scheme for dealing with crippled children was begun. Twenty-four beds were retained at the Bath Children's Orthopædic Hospital, and a number of centres are provided throughout the county at which the orthopædic surgeon and nurse attend. All varieties of crippling defects are included in the scheme. A fuller account will be given of the results achieved in next year's report. The pollution of rivers from milk depôts gave little trouble during 1925. The number of houses erected, 1386, was a considerable increase on any of the previous three years, the numbers of which were 995, 646, and 973. Meat inspection is carried out well in some districts, poorly in others. During the year the county council provided a special course of lectures and demonstrations for the sanitary inspectors of the county at the well-equipped Weston-super-Mare public abattoir. About 30 inspectors attended. Dr. Savage finds that in some cases butchers who give written notice of intention to slaughter at fixed times on fixed dates in some cases slaughter at other times without giving the required notice and so avoid inspection. Graded milks make some progress; thus at the end of 1925 there were in the county 4 producers of Certified Milk, 5 of Grade A (tuberculin tested), and 4 of Grade A, to be compared with 1, 1, and 2 respectively for 1924.

Gloucestershire.

Dr. J. Middleton Martin made an inquiry into the geographical distribution of fatal diseases in his county during the decade 1901–10. He has followed this with a similar inquiry for the decade 1911–20. The general result of the earlier inquiry was the conclusion that the most important factor was the circumstances of the home as opposed to the more remote environment. In comparing the two decades it is to be noted that at the earlier period the deaths under one year and the deaths from one to five years constituted 15 and 6 per cent. respectively of the total deaths, whereas during 1911–20 the deaths under one year were only 10·2 per cent. and the deaths from one to five years 4·4 per cent. of the total mortality. The evidence from the study of the

geographical distribution of disease brings out the fact that there is a very large incidence of enlargement of the thyroid gland among school-children in the area following the Cotswold Hills from the north-east of the county to the outskirts of Bristol, with parallel bands of low incidence following the Severn and of very low incidence on the west of the Severn. There are two curious exceptions. West Dean R.D. has a high rate in the area of lowest incidence, while Stow-on-the-Wold R.D. has a very low rate in the area of high incidence. On the Cotswolds the water is usually hard and pollution not more than in other places. The local waters in the Severn valley are also hard. On the west of the Severn the most striking fact is the exceptionally high rate for West Dean, which surrounds an urban district, of almost identical circumstances, with a very low rate. The contrast between the west and east sides of the forest may be due to the fact that West Dean has a doubtful water-supply, whereas the east side of the forest has mostly a public water-supply of good quality. Other conclusions resulting from this inquiry were that pediculosis in the head is most prevalent in agricultural districts and in areas where there is much female labour; that the distribution of pulmonary tuberculosis tends to be the converse of that for other forms of tuberculosis, and that bronchitis seems to be an illness of sheltered rather than of exposed conditions, whilst the reverse holds for pneumonia. In the surveys for both decades Dr. Martin suggests that the lesson may be—the great importance of the immediate as compared with the remote environment.

During 1925 midwives attended 64 per cent. of the births and sent for medical help in over 28 per cent. of their cases. It is now very rare for an uncertified woman to act as a midwife. The scheme for the extension of medical services makes steady progress with a corresponding lessening of expense. Thus if 1925 be compared with 1922 the total cost per attendance has been reduced from 15*s.* 6*d.* to 7*s.* 11¾*d.*; the cost of medical officers per attendance at out station from 4*s.* 3½*d.* to 2*s.* 0¼*d.*; and the cost of specialist's services per case from 12*s.* to 8*s.* 8½*d.* The work is carried out at three general hospitals and 11 out stations. The chief feature of the scheme in 1925 has been the extension of the orthopædic service. The orthopædic surgeon is Mr. J. S. Robinson, of the Cheltenham General Hospital, at which institution ten beds have been retained. An orthopædic nurse began work in November. The future development of this service is at present under consideration, and the construction of a hospital for crippled children may be the result.

Progress has been made, as the result of better transport facilities, in making the isolation hospitals serve wider districts. The year 1925 saw greater activity in the provision of houses, and an encouraging feature is the steady increase in the number of houses built by private enterprise from 53 in 1919 to 718 in 1925. Dr. Martin hopes that more will be done in the way of renovation and enlargement of existing houses, and is of opinion that the grants for repairing work which will shortly be available will act as a valuable stimulus to improved housing.

INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED NOV. 20TH, 1926.

Notifications.—The following cases of infectious disease were notified during the week: Small-pox 353 (last week 218), scarlet fever 2110, diphtheria 1133, enteric fever 55, pneumonia 1123, puerperal fever 57, puerperal pyrexia 166, cerebro-spinal fever 7, acute poliomyelitis 47, acute polio-encephalitis 4, encephalitis lethargica 46, dysentery 6, ophthalmia neonatorum 90. There were no cases of cholera, plague, or typhus fever notified during the week. The total of cases of acute poliomyelitis and polio-encephalitis taken together—namely, 51—is substantially higher than last week, 10 cases having been notified from the County of London, 3 of them from Wandsworth, the others widely scattered; the other counties reporting more than 3 cases were Devon 4, Lancaster 4; there were no cases reported from Rutland and only 3 from Kent—namely, 1 each from Beckenham, Tunbridge Wells, and Eastry R.D. Of the 353 cases of small-pox, 288 were reported from the county of Durham, only 5 of these from Gateshead C.B., the remainder scattered over 18 urban and rural districts, Brandon and Byshottles standing first with 92, Lanchester second with 41; Northumberland reported only 4 cases, 1 from Newcastle C.B., 3 from Ashington; the West Riding of Yorkshire reported 38 cases—viz., 3 from Sheffield, 6 from Doncaster, 12 from Mexborough, and the remainder from seven urban and rural districts; Derby reported 16 cases, 4 from the county borough, the others from five districts; Lancaster reported 5 (Ashton-in-Makerfield 4, Golborne 1); Nottingham 1 (Sutton-in-Ashfield); Yorks, North Riding 1 (Middlesbrough).

Deaths.—In the aggregate of great towns, including London, there was no death from small-pox, 1 (0) from enteric fever, 6 (1) from measles, 3 (0) from scarlet fever, 28 (3) from whooping-cough, 32 (10) from diphtheria, 68 (15) from diarrhœa and enteritis under 2 years, and 78 (19) from influenza. The figures in parentheses are those for London itself.

The Services.

ROYAL NAVAL MEDICAL SERVICE.

THE following appts. have been notified:—Surg. Comdrs.: J. G. Danson to *Maidstone*; G. O. M. Dickenson to *Victory*, for Royal Marine Infirmary, Portsmouth; and F. E. Anley to *Weymouth*, and as Fleet Medical Officer.

Surg. Lt.-Comdr. G. L. Ritchie to *Lowestoft*, on recommg.

Surg. Lts.: D. H. Kernohan to *Ganges*, for R.N. Sick Quarters, Shotley, temp., addl; and J. F. Kirwan to *Adamant*.

ROYAL NAVAL VOLUNTEER RESERVE.

Prob. Surg. Lt. R. B. H. Wyatt to be Surg. Lt.

Surg. Lt. T. W. Drummond to be Surg. Lt.-Comdr.

ROYAL ARMY MEDICAL CORPS.

Maj. O. C. P. Cooke retires on retd. pay, and is granted the rank of Lt.-Col.

Capts. H. D. F. Brand and C. Armstrong to be Majs.

Capt. W. I. F. Powell is secd. for duty with the Sudan Def. Force.

TERRITORIAL ARMY.

Maj. W. F. Munro resigns his commn. and is granted the rank of Lt.-Col. with permission to wear the prescribed uniform.

D. G. Robinson to be Lt.

Capt. M. C. Paterson, R.A.M.C., to be Divl. Adjt., 50th (Northumbrian) Div., vice Capt. J. M. Mackenzie, vacated.

Lt. E. L. Hancock is secd.

ROYAL AIR FORCE.

Flight Lt. P. A. Hall is promoted to the rank of Squadron Leader.

Flying Officer J. Parry-Evans is promoted to the rank of Flight Lt.

Temp. Capt. J. R. Williams, General List (Army), Dental Surgeon, is granted a temporary commission as a Flight Lt.

Flight Lt. J. S. Smith (Capt., Army Dental Corps) relinquishes his temporary commission on return to Army duty.

INDIAN MEDICAL SERVICE.

The King has approved the relinquishment of their temporary commissions by the following officers: Capts. Dhirendra Prasad Bose, Gopal Das Malhotra, Balkrishna, M.B., Aswini Kumar Nandi, Pramatha Nath Ghosh, Palathunkal Mathen Matthai, Antonelli Saldanha, Chhaganlal Motichand Contractor, Amulya Prasad Maitra, Mancher-shaw Ardeshir Mithavala, Madhav Vithal Pathak (these officers are permitted to retain the rank of Capt.). Sobha Ram Puri, Narayan Das Mehta, Munshi Ram Gupta, Jiban Ratam Dhar, Hem Chandra Mitter, Rustim Edulji Dadachanji, Vishnu Kashinath Parab, Jehangir Hormusjee Clarke.

Maj.-Gen. Sir Charles Mac. Watt has retired from service.

Dr. Kashi Prasad Bhatnagar, of the temporary Provincial Medical Service, medical officer in immediate charge of the Chamoli Dispensary, Garhwal, to officiate as Civil Surgeon, Garhwal, during the absence on leave of Dr. L. V. Jaensch.

Maj. E. G. A. Mathews, Civil Surgeon, on return from leave, is posted to Hardoi. Dr. Ganga Prased Rawat, officiating Civil Surgeon, is posted to Jalaun (Orai) from Hardoi.

Dr. Ganga Charan Garg, of the Provincial Medical Service, Medical Officer in immediate charge of the Sadr Dispensary, Rae Bareli, to the District Jail, Lucknow, for temporary duty. Col. G. Tate succeeds Col. A. W. R. Cochrane as Inspector-General of Civil Hospitals of the United Provinces.

Dr. A. C. Bentley, Director of Public Health, Bengal, is granted an extension of leave for 16 days.

GENERAL MEDICAL COUNCIL.

PENAL CASES.

TUESDAY, NOV. 23RD.

IN accordance with the usual custom the penal cases were heard in public, the Council deliberated on them in camera, and the results were then announced.

The Registrar read reports by the Dental Board of the United Kingdom on the cases of William Laird, registered on Feb. 18th, 1925, as of 6, Hartington-street, Belfast, "Dentist, 1921," charged with employing persons to canvass for him; of Hubert Lancelot Terry Bramley, registered on Jan. 6th, 1923, as of 13, Bracton-drive, Gordon-road, Nottingham, "Dentist, 1921," charged with personal canvassing; and of John William Marsh, registered on Sept. 11th, 1922, as of "Glenthorne," High-street, Thame, Oxon, "Dentist, 1921," who had been convicted and imprisoned for obtaining goods on false pretences. The Board had considered that the names of all these practitioners should be erased from the Dental Register. The Council ordered that they be erased.

The Case of Hira Lal Basu, registered as of 87B, Park-street, Calcutta, India, L.M.S. Calcutta, 1899, F.R.F.P.S. Glasg., 1913. This practitioner had been summoned to appear before the Council on the charge of advertising his arrival in Rangoon by paragraphs in local newspapers in 1925, and by causing articles to be published in these papers in which he claimed to be able to perform the "Steinach operation" for rejuvenation. Mr. Basu did not appear and was not represented. The Council's solicitor read a letter from him in which he stated that an acquaintance had lured him to Rangoon with the promise of a 3000 guinea fee, and that the offending matter was published without his knowledge. The Council ordered that his name be erased from the Register.

The Case of Egerton Carl White, registered as of 238, High-street, Cheltenham, M.B., Ch.B., 1912, U. Glasg., charged with abusing his position by committing adultery with a married woman with whom he stood in professional relationship. Dr. White was represented by Mr. O. Hempson, solicitor. The solicitor for the Council stated that Dr. White had performed two operations on Mrs. Watson in 1922 and that in September, 1924, they had started to live together. A divorce had been granted to Mr. Watson in May, 1925, and made absolute in November, 1925. Dr. White, giving evidence in his own defence, stated that he had first met Mrs. Watson socially at the end of 1921, and had become her friend and then her lover. Their sexual relationship had begun shortly after Christmas. They would have gone away openly then, but that Dr. White was in debt to his wife's family for certain capital with which he had set up in practice, and until he had paid this off he did not feel he was justified in taking that step. Mrs. Watson suffered from dysmenorrhœa and had naturally asked his advice; he had recommended curettage and she had preferred that he should perform this operation. He had done so twice in 1922. He had exercised his medical skill as a friend and not as a professional man and had rendered no account. In 1924, since he had then cleared himself of debt, he and Mrs. Watson made their relationship public. Mrs. Watson corroborated. Cross-examined about a sum of money Mr. Watson said he had given her to pay for her operation, she stated that she had asked for it for other purposes. There was no evidence that the sum was paid to Dr. White. The Council found that the facts alleged against Dr. White were not proved to their satisfaction and dismissed the case.

The Case of Thomas Blaney, registered as of 17, Saville-place, London, S.E. 1, L.R.C.P. Edin., 1920, L.R.C.S. Edin., 1920, L.R.F.P.S. Glasg., 1920. This practitioner had been convicted in 1925 for being drunk and incapable and was also charged with being drunk when certain patients were under his professional care. Mr. Blaney, who was represented by a solicitor, stated that he had suffered from domestic trouble which had induced him to drink to excess, but he had now been a teetotaller for four months. He produced two patients as witnesses to his good character. The Council postponed judgment for one year on the assurance of the respondent that he would abstain from alcohol during that time, and required him to forward evidence of his continued good conduct before their next November session.

The Case of Robert John Campbell, registered as of 7, Bradford-street, Ancoats, Manchester, M.B., Ch.B., 1922, Aberd., who appeared before the Council charged with having been convicted of drunkenness in 1923 and of having been convicted in May, 1926, of being drunk in charge of a motor-car and of driving to the public danger. Dr. Campbell's defence was that he had performed three operations on the day when the alleged offence was committed and was under the influence of chloroform, to which he was highly susceptible. He had had nothing to drink but a glass of beer and one whisky all day, but was sleepy because of the anæsthetic. This defence had not been given its full weight by the magistrate who had tried the case. The Council decided, on Dr. Campbell's undertaking to abstain altogether from alcohol in the future, not to erase his name from the Register.

The Case of Percy Bateman, registered as of 423, New Cross-road, S.E. 14, L.R.C.P. Edin., 1906, L.R.C.S. Edin., 1906, L.F.P.S. Glasg., 1906, who had been convicted on four occasions for drunkenness, three of them during the last six years. Mr. Bateman undertook to abstain from alcohol, saying also that he was taking a long rest from practice. The Council suspended judgment for a year under the customary guarantees.

The Council then considered business in camera until the end of their Wednesday sitting.

THURSDAY, NOV. 25TH.

The Case of David Davey Rosewarne, registered as of 2, Vere-street, London, W. 1, M.R.C.S. Eng., 1909, L.R.C.P. Lond., 1909, charged with abusing his position as a medical man by seducing a patient whom he was attending professionally, and also with having sexual intercourse with her on divers subsequent occasions while she was still his patient. The Council heard this case in camera, and decided to erase the name of Mr. Rosewarne from the Register.

EXECUTIVE COMMITTEE.

At a meeting of the Executive Committee the official notification was made of the reappointment of the following members of the Council: Mr. Samuel Osborn, Prof. J. B. Leathes, Dr. E. Magennis, Dr. D. J. Coffey, Sir J. W. Moore, and Dr. A. W. Mackintosh.

The following names, erased under Section 14 of the Medical Act, 1858, were restored to the Medical Register: Alexander Girvan, J. E. Hannigan, Sir Robert Porter, Henry C. E. Quin, F. G. Ralston.

The Poisons and Pharmacy Acts.

A communication from the Privy Council was read, in which the General Medical Council were asked to nominate a representative to serve on a committee appointed to consider the scope and administration of the Poisons and Pharmacy Acts. The President expressed his willingness to serve in the meantime, but doubted whether he would be able to continue a member after the November meeting. He was nominated by an unanimous vote.

Dangerous Drugs Regulations.

In the regulations made under Section 7 of the Dangerous Drugs Act, 1920, amending the Dangerous Drugs Regulations, 1921, and dated August 27th, 1926, the Secretary of State is empowered to refer the question of whether a medical practitioner is administering dangerous drugs otherwise than as required for purposes of medical treatment, to a tribunal in England of three members, one each to

be nominated by the General Medical Council, the Royal College of Physicians, and the British Medical Association. A similar tribunal is to be set up in Scotland with a nominee from the Royal College of Physicians of Edinburgh in place of that from the Royal College of Physicians of London. Sir Humphry Rolleston, with Dr. Wardrop Griffith and Dr. R. B. Wild as substitutes, was nominated for England, and Dr. A. Mackintosh, with Dr. J. A. Adams as substitute, for Scotland.

Sir Nestor Tirard was nominated by the Council to sit on the Advisory Committee newly appointed by the Ministry of Health to make regulations under the Therapeutic Substances Act.

Medical Practice in Malta.

Under Ordinance No. XVII. of 1901, amended 1906 and 1921, no one may practise the medical profession in Malta without a licence from the head of the Government. This licence is granted to any British subject producing a certificate from the Medical Board showing that he is a British subject of full age and is qualified by a recognised university or under the provisions of an Act of the Imperial Parliament. Physicians so licensed have certain duties which they must carry out, under penalty of fines for the first offence and imprisonment for the second. They are obliged to attend urgent cases by day or by night, to report to the superintendent of the public health anything they observe that may affect it, and to inform the police of every case of serious bodily harm, every death, and every birth at which no midwife has been present. Physicians are prohibited from practising pharmacy, and it is forbidden to employ any conventional sign in a prescription.

The amended Act was read before the Executive Committee.

OTHER BUSINESS.

On Thursday, Nov. 25th, the General Council ordered the following names to be restored to the Medical Register: David Williamson Anderson, removed 1925; Edwin Ernest Willis, removed 1922; William Joseph Ryan, removed 1926.

The Council received reports from the Education' Examination, Public Health, and Pharmacopœia Committees.

The number of copies of the British Pharmacopœia sold in the year ending Nov. 20th was 2401, an increase over last year.

The English Branch Council nominated Mr. L. P. Gamgee as a member of the Examination Committee in place of Dr. W. L. H. Duckworth, who has resigned his seat on the Council.

LEEDS AND WEST RIDING MEDICO-CHIRURGICAL SOCIETY.—At a meeting of this society on Nov. 19th Dr. Crawford Watson took the chair, and Dr. Wilfrid Edgecombe (Harrogate) read a paper on Vaccine Therapy in General Practice. Prophylactic immunisation, he said, depended mainly on the specific reaction to a vaccine, whereas curative immunisation appeared to depend mainly on the non-specific factor. General, focal, and local reactions might be caused by injection of a non-specific vaccine. In treating chronic infective diseases with vaccines three conditions should be fulfilled: the organism of the vaccine should be the true causal organism of the disease; the vaccine should be autogenous; and the source of infection should be located and removed if possible. He condemned speculative vaccines made from the bowel, or other source on the assumption, without adequate proof, that therein lay the source of infection. Any good from such vaccines must be due to the non-specific reaction, of the same order as the familiar protein-shock reaction. Prophylactic immunisation by vaccines in certain diseases, such as small-pox and typhoid, stood upon firm ground. Curative immunisation was on a less secure footing, and much of the vaccine therapy of the present day was purely empirical. A case of cervical rib was shown by Mr. E. R. Flint, and Dr. William MacAdam demonstrated a case of intermittent hydrarthrosis; whilst other patients were shown by Dr. J. Stewart, Dr. C. W. Vining, Dr. Cecilia Shiskin, Dr. R. Veale and Mr. A. Richardson, and radiographs by Dr. H. B. Scargill.

Correspondence.

"Audi alteram partem."

MEDICAL SCHOOLS AND THE LONDON UNIVERSITY BILL.

To the Editor of THE LANCET.

SIR,—The alterations in the constitution of the University of London which are proposed by the Departmental Committee will, in my opinion, be thoroughly advantageous.

The academic government of the University is at present in the hands of a Senate of 55, of whom 17 are nominees of the Crown or of bodies who have nothing officially to do with teaching. The future Senate will be a body of 48, of whom 25 will be directly concerned with teaching, 16 will be, as at present, the guardians of the interests of external students, and 5 will be coöpted by the Senate. It will be a much better body for academic purposes than the present Senate.

The present Senate is an extremely bad body for purposes of finance and general policy, and I do not think that the future one is likely to be any better. It is proposed to place those matters in the hands of a smaller body—the Council, on which the Senate will have a majority (eight members), and the Crown and the L.C.C. will appoint six. Such a body exists, I believe, in all English Universities except Oxford and Cambridge, and works well. There is no reason why it should not work well in London. The Council would act on the same principles as those on which the University Grants Committee now acts, and would be far less dictatorial than the L.C.C. now finds it necessary to be.
